Infiltration refers to the use of the filtration, adsorption, and biological decomposition properties of soils to remove pollutants prior to the intentional routing of runoff to the subsurface for groundwater recharge. Infiltration BMPs are a type of Retention BMP and include [infiltration basins](#), [infiltration trenches](#), [bioretention](#) without an underdrain, [dry wells](#), [permeable pavement](#), and [proprietary infiltration devices](#). Infiltration can provide multiple benefits including pollutant removal, hydromodification control, groundwater recharge, and flood control. However, conditions that can limit the use of infiltration include soil properties and potential adverse impacts on groundwater quality. A geotechnical investigation must be conducted when evaluating infiltration to determine the suitability of the site soil in adequately addressing groundwater protection. This may include an in-situ percolation test, per the guidance provided in Appendix C, and the determination of minimum depth to groundwater. The minimum separation to seasonal high groundwater or estimated mounded groundwater is five feet. Depth to seasonal high groundwater level shall be estimated as the average of the annual minima (i.e., the shallowest recorded measurements in each water year, defined as October 1 through September 30) for all years on record. If groundwater level data are not available or not considered to be representative, seasonal high groundwater depth can be determined by redoximorphic analytical methods combined with temporary groundwater monitoring for November 1 through April 1 at the proposed project site.

Soils should have sufficient organic content and sorption capacity to remove certain pollutants, but must be coarse enough to infiltrate runoff in a reasonable amount of time (e.g., < 72 hours for above-ground ponded water to prevent vector breeding). Examples of suitable soils are silty and sandy loams. Coarser soils, such as gravelly sands, have limited organic content and high permeability and therefore present a potential risk to groundwater from certain pollutants, especially in areas of shallow groundwater. Prior to the use of infiltration BMPs, consult with the local permitting agency to identify if vulnerable unconfined aquifers are located beneath the project to determine the appropriateness of these BMPs. In an area identified as an unconfined

aquifer, the application of infiltration BMPs should include significant pretreatment to ensure groundwater is protected from pollutants of concern.

Infiltration BMPs should not be placed in high-risk areas such as at or near service/gas stations, truck stops, and heavy industrial sites due to the groundwater contamination risk. Infiltration BMPs may be placed in high-risk areas if a site-specific evaluation demonstrates that sufficient pretreatment is provided to address pollutants of concern, high risks areas are isolated from stormwater runoff, or infiltration areas have little chance of spill migration.

In addition, infiltration BMPs must be sited at least 50 feet away from slopes steeper than 15 percent or an alternative setback established by the geotechnical expert for the project. Adequate spacing (100 feet or more) must be provided between infiltration BMPs and potable wells, non-potable wells, drain fields, and springs. Infiltration BMPs must be setback from building foundations at least eight feet or have an alternative setback established by the geotechnical expert for the project.

Infiltration is not allowed at locations with contaminated soils or groundwater where the pollutants could be mobilized or exacerbated by infiltration, unless a site-specific analysis determines the infiltration would not be detrimental. A site-specific analysis shall be prepared where pollutant mobilization (e.g., naturally-derived groundwater pollutants) is a concern. Projects must consider the potential for mobilization of groundwater contamination from natural sources as a result of stormwater infiltration (e.g., marine sediments, selenium-rich groundwater) to the extent that data is available.

Incidental infiltration that occurs in other types of Biofiltration BMPs and Treatment Control Measures, such as dry extended detention basins, vegetation swales, filter strips, and bioretention areas with underdrains, pose little risk to groundwater quality as treatment is provided in the BMP prior to infiltration.

Biofiltration BMPs

Biofiltration BMPs use vegetation and soils or other filtration media for runoff treatment. As runoff passes through the vegetation and filtration media, the combined effects of filtration, adsorption, and biological uptake remove pollutants. In biofiltration BMPs, pore spaces and organic material in the soils help to retain water in the form of soil moisture and to promote the pollutant adsorption (e.g., dissolved metals and petroleum hydrocarbons) into the soil matrix. Plants use soil moisture, promote the drying of the soil through transpiration, and uptake pollutants in their roots and leaves. Plants with extensive root systems also help to maintain filtration rates. Vegetation also decreases the velocity of flow and allows for particulates to settle.

Treatment Control Measures

Filtration

Various media, such as sand, perlite, zeolite, compost, and activated carbon, can be used in filtration BMPs to effectively remove total suspended solids (TSS) and associated pollutants such as organics (hydrocarbons and pesticides) and particulate metals. Filtration systems can be configured in the form of horizontal beds, trenches, or lastly, cartridge systems in underground vaults or catch basins.

Wetpools

A wetpool is a permanent pool of water incorporated into a wetpond or stormwater wetland BMP. Wetpools provide runoff treatment by allowing settling of particulates (sedimentation) by biological uptake and by vegetative filtration (if vegetation is present). Wetpool BMPs may be single-purpose facilities, providing only runoff treatment, or they may also provide flow control by providing additional detention storage with the use of a multi-stage outlet structure. If combined with detention, the wetpool volume can often be stacked under the detention volume with little further loss of development area.

“On-line” and “Off-line” Facilities

The location and configuration of control facilities can vary depending on the desired function. For example, drop structures or grade control may be located in a drainage channel so as to stabilize a channel for hydromodification control purposes. Such facilities are referred to as “in-stream” controls. Retention BMPs, Biofiltration BMPs, and Treatment Control Measures may not be located in-stream. Retention BMPs, Biofiltration BMPs, and Treatment Control Measures cannot be located in Waters of the US, but rather must be located upland to retain or treat runoff prior to discharge into Waters of the US.

If a Retention BMP, Biofiltration BMP, or Treatment Control Measure facility is designed such that all the runoff passes through the facility, the facility is called an “on-line” system. However, care must be taken to limit the resuspension of previously captured pollutants or damage to BMP performance during high flows. If, on the other hand, the facility only receives flows less than or equal to the stormwater quality design flow (SQDF), the facility is called an “off-line” system. Off-line systems therefore require a flow splitter or equivalent device. Generally treatment performance is better for off-line facilities because a larger percentage of the runoff is treated. Figure 6-1 illustrates the difference between on-line, off-line, and in-stream controls.

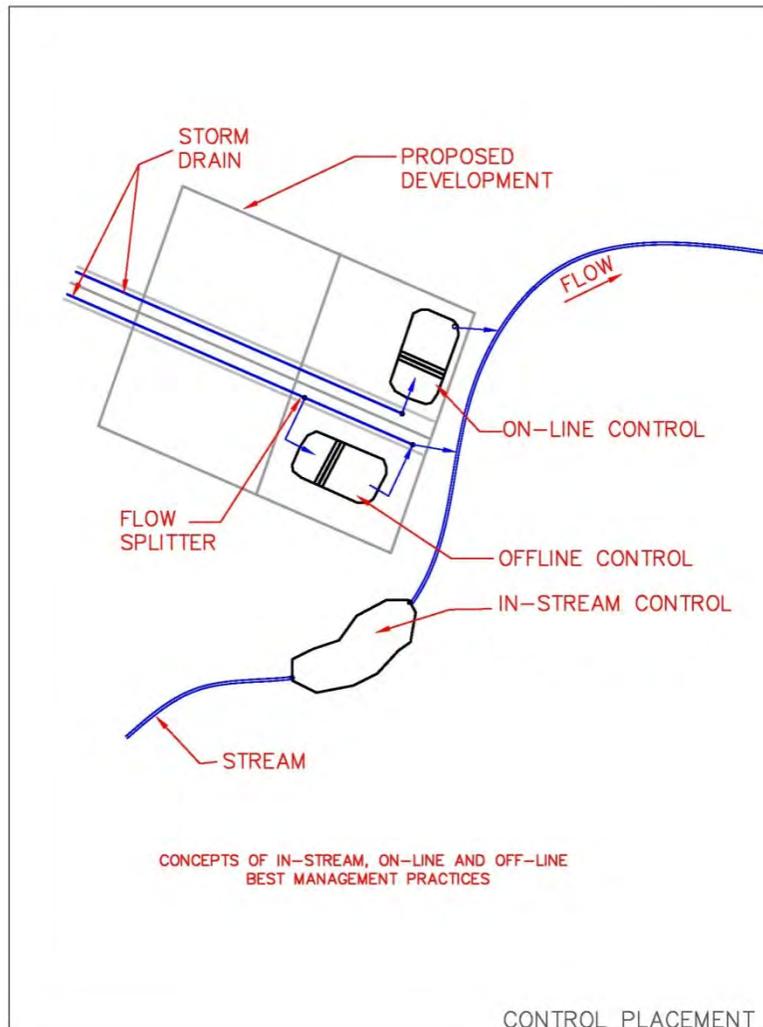

Figure 6-1: Differences between On-line, Off-line, and In-stream Control Measures

6.3 Retention BMP, Biofiltration BMP, and Treatment Control Measure Fact Sheets

This section provides fact sheets with recommended criteria for the design and implementation of Retention BMPs, Biofiltration BMPs, and Treatment Control Measures. The siting, design, and maintenance requirements in the fact sheets are intended to ensure optimal performance of the measures. Alternative designs may be approved by the local permitting authority based on site specific conditions if equivalent pollutant removal performance is provided.

The 2011 TGM also contains calculation worksheets to aid in the design of these BMPs in Appendix E. New BMPs that are equivalent to those included in the 2011 TGM are acceptable based on approval of the local permitting agency.

Fact sheets are provided for the Retention BMPs, Biofiltration BMPs, and Treatment Control Measures listed below:

Retention BMPs

Infiltration BMPs

- [INF-1: Infiltration Basin](#)
- [INF-2: Infiltration Trench](#)
- [INF-3: Bioretention](#)
- [INF-4: Drywell](#)
- [INF-5: Permeable Pavement](#)
- [INF-6: Proprietary Infiltration](#)

Rainwater Harvesting BMPs

- [RWH-1: Rainwater Harvesting](#)

Evapotranspiration BMPs

- [ET-1: Green Roof](#)
- [ET-2: Hydrologic Source Controls](#)

Biofiltration BMPs

- [BIO-1: Bioretention with Underdrain](#)
- [BIO-2: Planter Box](#)
- [BIO-3: Vegetated Swale](#)
- [BIO-4: Vegetated Filter Strip](#)
- [BIO-5: Proprietary Biotreatment](#)

Treatment Control Measures

- [TCM-1: Dry Extended Detention Basin](#)
- [TCM-2: Wet Detention Basin](#)
- [TCM-3: Constructed Wetland](#)
- [TCM-4: Sand Filter](#) (if vegetated, this is considered a Biofiltration BMP)
- [TCM-5: Cartridge Media Filter](#)

Pretreatment/Gross Solids Removal BMPs

- [PT-1: Hydrodynamic Device](#)
- [PT-2: Catch Basin Insert](#)

INF-1: Infiltration Basin

An infiltration basin consists of an earthen basin constructed in naturally pervious soils (Type A or B soils) with a flat bottom and provided with an inlet structure to dissipate energy of incoming flow and an emergency spillway to control excess flows. An optional relief underdrain may be provided to drain the basin if standing water conditions occur. A forebay settling basin or separate Treatment Control Measure must be provided as pretreatment. An infiltration basin functions by retaining the SQDV in the basin and allowing the retained runoff to percolate into the underlying native soils over a specified period of time. The bottoms of infiltration basins are typically vegetated with dry-land grasses or irrigated turf grass. A typical layout of an infiltration basin system is shown in Figure 6-2.

Infiltration Basin in a Fresno, CA Park, Before and After a Rain Event

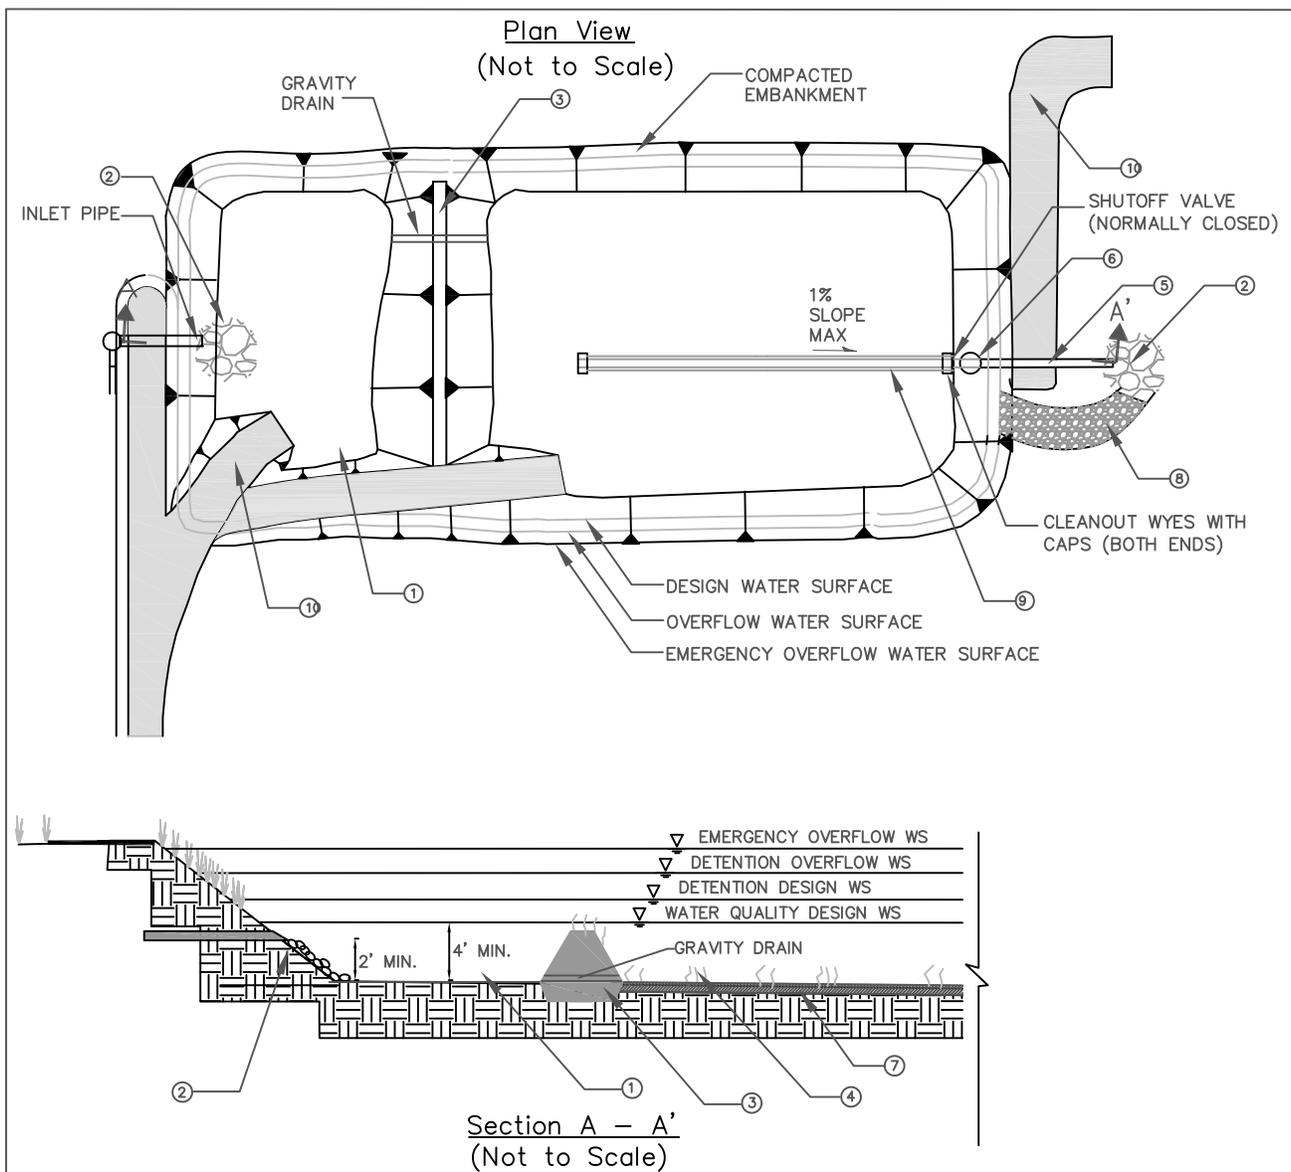

Photo Credit: Geosyntec Consultants

Application

- Mixed-use and commercial
- Roads and parking lots
- Parks and open spaces
- Single and multi-family residential
- Can integrate with parks

Routine Maintenance

- Removal trash, debris, and sediment at inlet and outlets
- Wet weather inspection to ensure drain time
- Remove weeds
- Inspect for mosquito breeding

NOTES:

- ① UPSTREAM PRETREATMENT SHALL BE PROVIDED. SEDIMENT FOREBAY WITH VOLUME EQUAL TO 25% OF TOTAL INFILTRATION BASIN VOLUME MAY BE USED IN LIEU OF UPSTREAM PRETREATMENT. DEPTH SHALL BE 4' MIN TO 8' MAX PLUS AN ADDITIONAL 1 FOOT MIN SEDIMENT STORAGE DEPTH.
- ② RIP RAP APRON OR OTHER ENERGY DISSIPATION.
- ③ EXTEND EARTHEN BERM ACROSS ENTIRE WIDTH OF THE INFILTRATION BASIN.
- ④ INFILTRATION BASIN BOTTOM AND SIDE SLOPES SHALL BE PLANTED WITH DROUGHT TOLERANT VEGETATION. DEEP ROOTED VEGETATION PREFERRED FOR BASIN BOTTOM. NO TOPSOIL SHALL BE ADDED TO INFILTRATION BASIN BED.
- ⑤ SIZE OUTLET PIPE TO PASS 100-YEAR PEAK FLOW FOR ON-LINE INFILTRATION BASINS AND WATER QUALITY PEAK FLOW FOR OFF-LINE INFILTRATION BASINS.
- ⑥ WATER QUALITY OUTLET STRUCTURE. SEE FIGURE 7-2 AND FIGURE 7-3 FOR DETAILS.
- ⑦ OVER EXCAVATE BASIN BOTTOM 1 FOOT. RE-PLACE EXCAVATED MATERIAL UNIFORMLY WITHOUT COMPACTION. AMENDING EXCAVATED MATERIAL WITH 2" - 4" OF COARSE SAND IS RECOMMENDED FOR SOILS WITH BORDER LINE INFILTRATION CAPACITY.
- ⑧ INSTALL EMERGENCY OVERFLOW SPILLWAY AS NEEDED. SEE FIGURE 2-4 FOR DETAILS
- ⑨ INSTALL OPTIONAL 6" MINIMUM DIAMETER PERFORATED PIPE UNDERDRAIN. INSTALL AT 0.5% MINIMUM SLOPE.
- ⑩ MAINTENANCE RAMP SHOULD PROVIDE ACCESS TO BOTH THE FIRST CELL AND MAIN BASIN.

	
Figure 6-2: Infiltration Basin	

Limitations

The following limitations should be considered before choosing to use an infiltration basin:

- Native soil infiltration rate - permeability of soils at the infiltration basin location must be at least 0.5 inches per hour.
- Depth to groundwater, bedrock, or low permeability soil layer – 5 feet vertical separation is required between the bottom of the infiltration basin and the seasonal high groundwater level or mounded groundwater level, bedrock, or other barrier to infiltration to ensure that the facility will completely drain between storms and that infiltrating water will receive adequate treatment through the soils before it reaches the groundwater.
- Slope stability - infiltration BMPs must be sited at least 50 feet away from slopes steeper than 15 percent or an alternative setback established by the geotechnical expert for the project.
- Setbacks - a minimum setback (100 feet or more) must be provided between infiltration BMPs and potable wells, non-potable wells, drain fields, and springs. Infiltration BMPs must be setback at least eight feet from building foundations or have an alternative setback established by the geotechnical expert for the project.
- Groundwater contamination - the application of infiltration BMPs should include significant pretreatment in an area identified as an unconfined aquifer to ensure groundwater is protected for pollutants of concern.
- Contaminated soils or groundwater plumes - infiltration BMPs are not allowed at locations with contaminated soils or groundwater, where the pollutants could be mobilized or exacerbated by infiltration, unless a site-specific analysis determines the infiltration would be beneficial.
- High pollutant land uses - infiltration BMPs should not be placed in high-risk areas such as at or near service/gas stations, truck stops, and heavy industrial sites due to the groundwater contamination risk unless a site-specific evaluation demonstrates that sufficient pretreatment is provided to address pollutants of concern, high risks areas are isolated from stormwater runoff, or infiltration areas have little chance of spill migration.
- High sediment loading rates – infiltration BMPs may clog quickly if sediment loads are high (e.g., unstabilized site) or if flows are not adequately pretreated.

Additional Control Functions

Infiltration basins can be designed for flow control by providing storage capacity in excess of that provided by infiltration and incorporating outlet controls. The additional storage and outlet structure should be provided per the requirements outlined in the [Dry Extended Detention Basins](#) section of the 2011 TGM. Note that the selected outlet structure should not be designed to drain the design volume intended for infiltration and should be similar to outlet structures that maintain a permanent pool (see Section 6.10.2 – Wet Retention Basins).

Multi-Use Opportunities

Infiltration basins may be integrated into the design of a park or playfield. Recreational multi-use facilities should be inspected after every storm and may require a greater maintenance frequency than dedicated infiltration basins to ensure aesthetics and public safety are not compromised. Any planned multi-use facility must obtain approval by the affected City and County departments.

Design Criteria

The main challenge associated with infiltration basins is preventing system clogging and subsequent infiltration inhibition. Infiltration basins should be designed according to the requirements listed in Table 6-1 and outlined in the section below. Detailed design procedures and an example are included in Appendix E.

Table 6-1: Infiltration Basin Design Criteria

Design Parameter	Unit	Design Criteria
Stormwater quality design volume (SQDV)	acre-foot	See Section 2.3 and Appendix E for calculating SQDV
Design drawdown time	hr	12 - 72 (See Appendix D, Section D.2)
Bottom basin Elevation	feet	5 feet above seasonally high groundwater table or mounded groundwater
Setbacks	feet	100 feet from wells, fields, and springs; 20 feet downslope of 100 feet upslope of foundations; Geotechnical expert should establish the setback requirement from building foundations that must be ≥ 8 ft.
Pretreatment	-	Sedimentation forebay or any Treatment Control Measure shall be provided as pretreatment for all tributary surfaces other than roofs.

Design Parameter	Unit	Design Criteria
Design percolation rate (P_{design})	in/hr	Measured percolation rate must be corrected based onsite suitability assessment and design related considerations described in this fact sheet.
Facility geometry	-	Forebay (if applicable): 25% of facility volume; flat bottom slope
Freeboard (minimum)	ft	1.0
Inlet/ Outlet erosion control	-	Energy dissipater to reduce velocity
Overflow device	-	Required if system is on-line

Geotechnical Considerations

An extensive geotechnical site investigation must be undertaken early in the site planning process to verify site suitability for the installation of infiltration facilities, due to the potential to contaminate groundwater, cause slope instability, impact surrounding structures, and have insufficient infiltration capacity.. Soil infiltration rates and the water table depth should be evaluated to ensure that conditions are satisfactory for proper operation of an infiltration facility. See Appendix C for guidance on infiltration testing.

The project designer must demonstrate through infiltration testing, soil logs, and the written opinion of a licensed civil engineer that sufficiently permeable soils exist onsite to allow the construction of a properly functioning infiltration facility.

- 1) Infiltration facilities require a minimum soil infiltration rate of 0.5 inches/hour. Pretreatment is required in all instances.
- 2) Groundwater separation must be at least 5 feet from the basin bottom to the measured [Seasonal High Groundwater Elevation](#) or estimated high groundwater mounding elevation. Groundwater levels measurements must be made during the time when water level is expected to be at a maximum (i.e., toward the end of the wet season).
- 3) Potential BMP sites with a slope greater than 25% (4:1) should be excluded. A geotechnical analysis and report addressing slope stability are required if located within 50 feet of slopes greater than 15%.

Soil Assessment and Site Geotechnical Investigation Reports

The soil assessment report should:

- State whether the site is suitable for the proposed infiltration basin;

- Recommend a design percolation rate (see “*Step 2: Determine The Design Percolation Rate*” below);
- Identify the seasonally high depth to groundwater table surface elevation;
- Provide a good understanding of how the stormwater runoff will move in the soil (horizontally or vertically) and if there are any geological conditions that could inhibit the movement of water; and
- If a geotechnical investigation and report are required, the report should:
 - Provide a written opinion by a professional civil engineer describing whether the infiltration basin will compromise slope stability; and
 - Identify potential impacts to nearby structural foundations.

Setbacks

- 1) Infiltration facilities shall be setback a minimum of 100 feet from proposed or existing potable wells, non-potable wells, septic drain fields, and springs.
- 2) Infiltration BMPs must be sited at least 50 feet away from slopes steeper than 15 percent or an alternative setback established by the geotechnical expert for the project.
- 3) The geotechnical expert shall establish the setback requirement from building foundations that must be ≥ 8 ft.

Pretreatment

Pretreatment is required for infiltration basins in order to reduce the sediment load entering the facility and maintain the infiltration rate of the facility. Pretreatment refers to design features that provide settling of large particles before runoff reaches a management practice; easing the long-term maintenance burden. Pretreatment is important for most all structural stormwater BMPs, but it is particularly important for infiltration BMPs. To ensure that pretreatment mechanisms are effective, designers should incorporate sediment reduction practices. Sediment reduction BMPs may include vegetated swales, vegetated filter strips, sedimentation basins or forebays, sedimentation manholes and hydrodynamic separation devices. The use of at least two pretreatment devices is highly recommended for infiltration basins.

For design specification of selected pretreatment devices, refer to:

- [BIO-3: Vegetated swales](#)
- [BIO-4: Vegetated filter strips](#)
- [TCM-4: Sand filters](#)

- [TCM-5: Cartridge media filters](#)
- [PT-1: Hydrodynamic separation device](#)

Sizing Criteria

As with sand filters, infiltration facilities can be sized using one of two methods: a simple sizing method or a routing modeling method. With either method the SQDV volume must be completely infiltrated within 12 to 72 hours (see Appendix D, Section D.2 for a discussion on drawdown time and BMP performance). The simple sizing procedures provided below can be used for either infiltration basins or infiltration trenches (see [INF-2: Infiltration Trench](#)). For the routing modeling method, refer to [TCM-4 Sand Filters](#).

Step 1: Calculate the Design Volume

Infiltration facilities shall be sized to capture and infiltrate the SQDV volume (see [Section 2](#) and Appendix E) with a 12 to 72 hour drawdown time (see Appendix D, Section D.2).

Step 2: Determine the Design Percolation Rate

The percolation rate will decline between maintenance cycles as the surface becomes occluded and particulates accumulate in the infiltrative layer. Monitoring of actual facility performance has shown that the full-scale infiltration rate is far lower than the rate measured by small-scale testing. It is important that adequate conservatism is incorporated in the selection of design percolation rates. For infiltration trenches, the design percolation rate discussed here is the percolation rate of the underlying soils and not the percolation rate of the filter media bed (refer to the “[Geometry and Sizing](#)” section of INF-2 for the recommended composition of the filter media bed for infiltration trenches).

Considerations for Design Percolation Rate Corrections

Suitability assessment related considerations include (Table 6-2):

- Soil assessment methods – the site assessment extent (e.g., number of borings, test pits, etc.) and the measurement method used to estimate the short-term infiltration rate.
- Predominant soil texture/percent fines – soil texture and the percent fines can greatly influence the potential for clogging.
- Site soil variability – site with spatially heterogeneous soils (vertically or horizontally), as determined from site investigations, are more difficult to estimate average properties resulting in a higher level of uncertainty associated with initial estimates.

- Depth to seasonal high groundwater/impervious layer – groundwater mounding may become an issue during excessively wet conditions where shallow aquifers or shallow clay lenses are present.

Table 6-2: Suitability Assessment Related Considerations for Infiltration Facility Safety Factors

Consideration	High Concern	Medium Concern	Low Concern
Assessment methods	Use of soil survey maps or simple texture analysis to estimate short-term infiltration rates	Direct measurement of ≥ 20 percent of infiltration area with localized infiltration measurement methods (e.g., infiltrometer)	Direct measurement of ≥ 50 percent of infiltration area with localized infiltration measurement methods or Use of extensive test pit infiltration measurement methods
Ventura Hydrology Manual soil number (measured infiltration rate)	3 ($f = 0.5 - 0.64$)	4 or 5 ($f = 0.65 - 0.91$)	6 or 7 ($f = 0.92$ or higher)
Site soil variability	Highly variable soils indicated from site assessment or limited soil borings collected during site assessment	Soil borings/test pits indicate moderately homogeneous soils	Multiple soil borings/test pits indicate relatively homogeneous soils
Depth to groundwater/impervious layer	<10 ft below facility bottom	10-30 ft below facility bottom	>30 below facility bottom

Localized infiltration testing refers to methods such as the double ring infiltrometer test (ASTM D3385-88), which measure infiltration rates over an area less than 10 sq-ft and do not attempt to account for soil heterogeneity. Extensive infiltration testing refers to methods that include excavating a significant portion of the proposed infiltration area, filling the excavation with water, and monitoring drawdown. In all cases, testing should be conducted in the area of the proposed BMP where, based on geotechnical data, soils appear least likely to support infiltration.

Design related considerations include (Table 6-3):

- Size of area tributary to facility – all things being equal, both physical and economic risk factors related to infiltration facilities increase with an increase in the tributary area served. Therefore facilities serving larger tributary areas should use more restrictive adjustment factors.
- Level of pretreatment/expected influent sediment loads – credit should be given for good pretreatment by allowing less restrictive factors to account for the reduced probability of clogging from high sediment loading. Also, facilities designed to capture runoff from relatively clean surfaces such as rooftops are likely to see low sediment loads and therefore should be allowed to apply less restrictive safety factors.
- Redundancy – facilities that consist of multiple subsystems operating in parallel such that parts of the system remains functional when other parts fail and/or bypass, should be rewarded for the built-in redundancy with less restrictive correction and safety factors. For example, if bypass flows would be at least partially treated by another BMP, the risk of discharging untreated runoff in the event of clogging the primary facility is reduced. A bioretention facility that overflows to a landscaped area is another example. Compaction during construction – proper construction oversight is needed during construction to ensure that the bottoms of infiltration facility are not overly compacted. Facilities that do not commit to proper construction practices and oversight should have to use more restrictive correction and safety factors.

Table 6-3: Design Related Considerations for Infiltration Facility Safety Factors

Consideration	High Concern	Medium Concern	Low Concern
Tributary area size	Greater than 10 acres.	Greater than 2 acres but less than 10 acres.	2 acres or less.
Level of pre-treatment/ expected influent sediment loads	Pre-treatment from gross solids removal devices only, such as hydrodynamic separators, racks and screens, AND tributary area includes landscaped areas, steep slopes, high traffic areas, or any other areas expected to produce high sediment, trash, or debris loads.	Good pre-treatment with BMPs that mitigate coarse sediments such as vegetated swales AND influent sediment loads from the tributary area are expected to be relatively low (e.g., low traffic, mild slopes, disconnected impervious areas, etc.).	Excellent pre-treatment with BMPs that mitigate fine sediments such as bioretention or media filtration OR sedimentation or facility only treats runoff from relatively clean surfaces, such as rooftops.
Redundancy of treatment	No redundancy in BMP treatment train.	Medium redundancy, other BMPs available in treatment train to maintain at least 50% of function of facility in event of failure.	High redundancy, multiple components capable of operating independently and in parallel, maintaining at least 90% of facility functionality in event of failure.
Compaction during construction	Construction of facility on a compacted site or elevated probability of unintended/ indirect compaction.	Medium probability of unintended/ indirect compaction.	Heavy equipment actively prohibited from infiltration areas during construction and low probability of unintended/ indirect compaction.

Adjust the measured short-term infiltration rate using a weighted average of several safety factors using the worksheet shown in Table 6-4 below. The design percolation rate would be determined as follows:

- For each consideration shown in Table 6-2 and Table 6-3 above, determine whether the consideration is a high, medium, or low concern.
- For all high concerns, assign a factor value of 3, for medium concerns, assign a factor value of 2, and for low concerns assign a factor value of 1.
- Multiply each of the factors by the corresponding weight to get a product.

- Sum the products within each factor category to obtain a safety factor for each.
- Multiply the two safety factors together to get the final combined safety factor. If the combined safety factor is less than 2, then use 2 as the safety factor.
- Divide the measured short-term infiltration rate by the combined safety factor to obtain the adjusted design percolation rate for use in sizing the infiltration facility.

Table 6-4: Infiltration Facility Safety Factor Determination Worksheet

Factor Category		Factor Description	Assigned Weight (w)	Factor Value (v)	Product (p) p = w x v
A	Suitability Assessment	Soil assessment methods	0.25		
		Predominant soil texture	0.25		
		Site soil variability	0.25		
		Depth to groundwater / impervious layer	0.25		
		Suitability Assessment Safety Factor, $S_A = \Sigma p$			
B	Design	Tributary area size	0.25		
		Level of pre-treatment/ expected sediment loads	0.25		
		Redundancy	0.25		
		Compaction during construction	0.25		
		Design Safety Factor, $S_B = \Sigma p$			
Combined Safety Factor = $S_A \times S_B$					

Note: The minimum combined adjustment factor shall not be less than 2.0 and the maximum combined adjustment factor shall not exceed 9.

Step 3: Calculate the surface area

Determine the size of the required infiltrating surface by assuming the SQDV will fill the available ponding depth plus (for infiltration trenches) the void spaces based on the computed porosity of the filter media (normally about 32%).

- 1) Determine the maximum depth of runoff that can be infiltrated within the required drain time (d_{max}) as follows:

$$d_{max} = \frac{P_{design}}{12} t \tag{Equation 6-1}$$

Where:

d_{max}	=	the maximum depth of water that can be infiltrated within the required drain time (ft)
P_{design}	=	design percolation rate of underlying soils (in/hr)
t	=	required drain time (hrs)

2) Choose the ponding depth (d_p) and/or trench depth (d_t) such that:

$$d_{max} \geq d_p \quad \text{For Infiltration Basins} \quad (\text{Equation 6-2})$$

$$d_{max} \geq n_t d_t + d_p \quad \text{For Infiltration Trenches} \quad (\text{Equation 6-3})$$

Where:

d_{max}	=	the maximum depth of water that can be infiltrated within the required drain time (ft)
d_p	=	ponding depth (ft)
n_t	=	trench fill aggregate porosity (unitless)
d_t	=	depth of trench fill (ft)

3) Calculate infiltrating surface area (filter bottom area) required:

$$A = \frac{SQDV}{((TP_{design} / 12) + d_p)} \quad \text{For Infiltration Basins} \quad (\text{Equation 6-4})$$

$$A = \frac{SQDV}{((TP_{design} / 12) + n_t d_t + d_p)} \quad \text{For Infiltration Trenches} \quad (\text{Equation 6-5})$$

Where:

$SQDV$	=	stormwater quality design volume (ft ³)
n_t	=	trench fill aggregate porosity (unitless)
P_{design}	=	design percolation rate (in/hr)
d_p	=	ponding depth (ft)
d_t	=	depth of trench fill (ft)
T	=	fill time (time to fill to max ponding depth with water) (hrs) [use 2 hours for most designs]

Geometry and Sizing

- 1) Infiltration basins should be designed and constructed with the flattest bottom slope possible to promote uniform ponding and infiltration across the facility.
- 2) A sediment forebay is required unless adequate pretreatment is provided in a separate pretreatment unit (e.g., vegetated swale, filter strip, hydrodynamic device) to reduce sediment loads entering the infiltration basin. The sediment forebay, if present, should have a volume equal to 25% of the total infiltration basin volume.
- 3) The forebay should be designed with a minimum length to width ratio of 2:1 and should completely drain to the main basin through an 8-inch minimum low-flow outlet within 10 minutes.
- 4) All inlets should enter the sediment forebay. If there are multiple inlets, the length-to-width ratio should be based on the average flowpath length for all inlets.
- 5) Design embankments to conform to requirements of the State of California Division of Safety of Dams, if the basin dimensions cause it to fall under that agency's jurisdiction.

Drainage

- 1) The bottom of the infiltration bed should be native soil, over-excavated to at least one foot in depth, and replaced uniformly without compaction. Amending the excavated soil with 2-4 inches (~15-30%) of coarse sand is recommended.
- 2) The hydraulic conductivity of the subsurface layers should be sufficient to ensure a maximum 72-hr drawdown time. An observation well shall be incorporated to allow observation of drain time.
- 3) For infiltration basins, an underdrain should be installed within the bottom layer to provide drainage in case of standing water. The underdrain should be operated by opening a valve, which should be closed during normal operation. Cleanouts should be provided for the underdrain. See Sand Filter Section VEG-8 for specifications for underdrains.

Emergency Overflow

- 1) There should be an overflow route for stormwater flows that overtop the facility or in case the infiltration facility becomes clogged.
- 2) The overflow channel should be able to safely convey flows from the peak design storm to the downstream stormwater conveyance system or other acceptable discharge point.

- 3) Spillway and overflow structures should be designed in accordance with applicable standards of the Ventura County Flood Control District or local jurisdiction.

Vegetation

- 1) A thick mat of drought tolerant grass should be established on the basin floor and side-slopes following construction. Grasses can help prevent erosion and increase evapotranspiration and their roots discourage compaction helping to maintain the surface infiltration rates. Additionally, the active growing vegetation can help break up surface layers that accumulate fine particulates.
- 2) Grass may need to be irrigated during establishment.
- 3) For infiltration basins, landscaping of the area surrounding the basin should adhere to the following criteria so as not to hinder maintenance operations:
 - a. No trees or shrubs may be planted within 10 feet of inlet or outlet pipes or manmade drainage structures such as spillways, flow spreaders, or earthen embankments. Species with roots that seek water, such as willow or poplar, should not be used within 50 feet of pipes.
 - b. Prohibited non-native plant species will not be permitted. For more information on invasive weeds, including biology and control of listed weeds, look at the [encycloweedia](#) located at the California Department of Food and Agriculture website or the California Invasive Plant Council website at www.cal-ipc.org.

Maintenance Access

- 1) Maintenance access road(s) shall be provided to the drainage structures associated with the basin (e.g., inlet, emergency overflow, or bypass structures). Manhole and catch basin lids should be in or at the edge of the access road.
- 2) An access ramp to the basin bottom is required to facilitate the entry of sediment removal and vegetation maintenance equipment without compaction of the basin bottom and side slopes.

Construction Considerations

To preserve and avoid the loss of infiltration capacity, the following construction guidelines are specified:

- 1) The entire area draining to the facility should be stabilized before construction begins. If this is impossible, a diversion berm should be placed around the perimeter of the infiltration site to prevent sediment entrance during construction.

- 2) Infiltration basins should not be hydraulically connected to the stormwater conveyance system until all contributing tributary areas are stabilized as shown on the Contract Plans and to the satisfaction of the Engineer. Infiltration basins should not be used as sediment control facilities.
- 3) Compaction of the subgrade with heavy equipment should be minimized to the maximum extent possible. If the use of heavy equipment on the base of the facility cannot be avoided, the infiltrative capacity should be restored by tilling or aerating prior to placing the infiltrative bed.
- 4) The exposed soils should be inspected by a civil engineer after excavation to confirm that soil conditions are suitable.

Operations and Maintenance

Infiltration facility maintenance should include frequent inspections to ensure that surface ponding infiltrates into the subsurface completely within the design infiltration time after a storm (see Appendix I for an infiltration BMP inspection and maintenance checklist).

Maintenance and regular inspections are of primary importance if infiltration BMPs are to continue to function as originally designed. A specific maintenance plan shall be formulated specifically for each facility outlining the schedule and scope of maintenance operations, as well as the data handling and reporting requirements. The following are general maintenance requirements:

- 1) Regular inspection should determine if the pretreatment sediment removal BMPs require routine maintenance.
- 2) If water is noticed in the basin more than 72 hours after a major storm the infiltration facility may be clogged. Maintenance activities triggered by a potentially clogged facility include:
 - a. Check for debris/sediment accumulation, rake surface, and remove sediment (if any) and evaluate potential sources of sediment and debris (e.g., embankment erosion, channel scour, overhanging trees, etc). If suspected upland sources are outside of the immediate jurisdiction, additional pretreatment operations (e.g., trash racks, vegetated swales, etc.) may be necessary.
 - b. For basins, removal of the top layer of native soil may be required to restore infiltrative capacity.
 - c. Any debris or algae growth located on top of the infiltration facility should be removed and disposed of properly.
 - d. Facilities shall be inspected annually. Trash and debris should be removed as needed, but at least annually prior to the beginning of the wet season.

- 3) Site vegetation should be maintained as frequently as necessary to maintain the aesthetic appearance of the site, and as follows:
 - a. Vegetation, large shrubs, or trees that limit access or interfere with basin operation should be pruned or removed.
 - b. Slope areas that have become bare should be revegetated and eroded areas should be regraded prior to being revegetated.
 - c. Grass should be mowed to 4" - 9" high and grass clippings should be removed.
 - d. Fallen leaves and debris from deciduous plant foliage should be raked and removed.
 - e. Invasive vegetation, such as Alligatorweed (*Alternanthera philoxeroides*), Halogeton (*Halogeton glomeratus*), Spotted Knapweed (*Centaurea maculosa*), Giant Reed (*Arundo donax*), Castor Bean (*Ricinus communis*), Perennial Pepperweed (*Lepidium latifolium*), and Yellow Starthistle (*Centaurea solstitialis*) should be removed and replaced with non-invasive species. Invasive species should never contribute more than 25% of the vegetated area. For more information on invasive weeds, including biology and control of listed weeds, look at the [encyclopededia](#) located at the California Department of Food and Agriculture website or the California Invasive Plant Council website at www.cal-ipc.org.
 - f. Dead vegetation should be removed if it exceeds 10% of area coverage. Vegetation should be replaced immediately to maintain cover density and control erosion where soils are exposed.
- 4) For infiltration basins, sediment build-up exceeding 50% of the forebay capacity should be removed. Sediment from the remainder of the basin should be removed when 6 inches of sediment accumulates. Sediments should be tested for toxic substance accumulation in compliance with current disposal requirements if land uses in the catchment include commercial or industrial zones, or if visual or olfactory indications of pollution are noticed. If toxic substances are encountered at concentrations exceeding thresholds of Title 22, Section 66261 of the California Code of Regulations, the sediment should be disposed of in a hazardous waste landfill and the source of the contaminated sediments should be investigated and mitigated to the extent possible.
- 5) Following sediment removal activities, replanting and/or reseeded of vegetation may be required for reestablishment.

INF-2: Infiltration Trench

Infiltration trenches are long, narrow, gravel-filled trenches, often vegetated, that infiltrate stormwater runoff from small drainage areas. Infiltration trenches may include a shallow depression at the surface, but the majority of runoff is stored in the void space within the gravel and infiltrates through the sides and the bottom of the trench.

Rural Highway Infiltration Trench

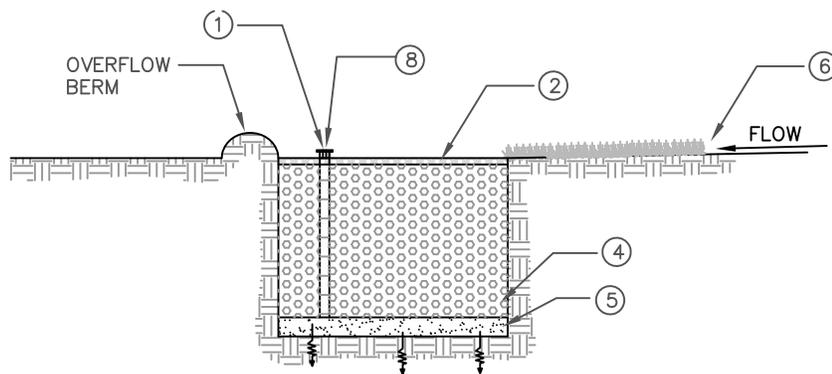

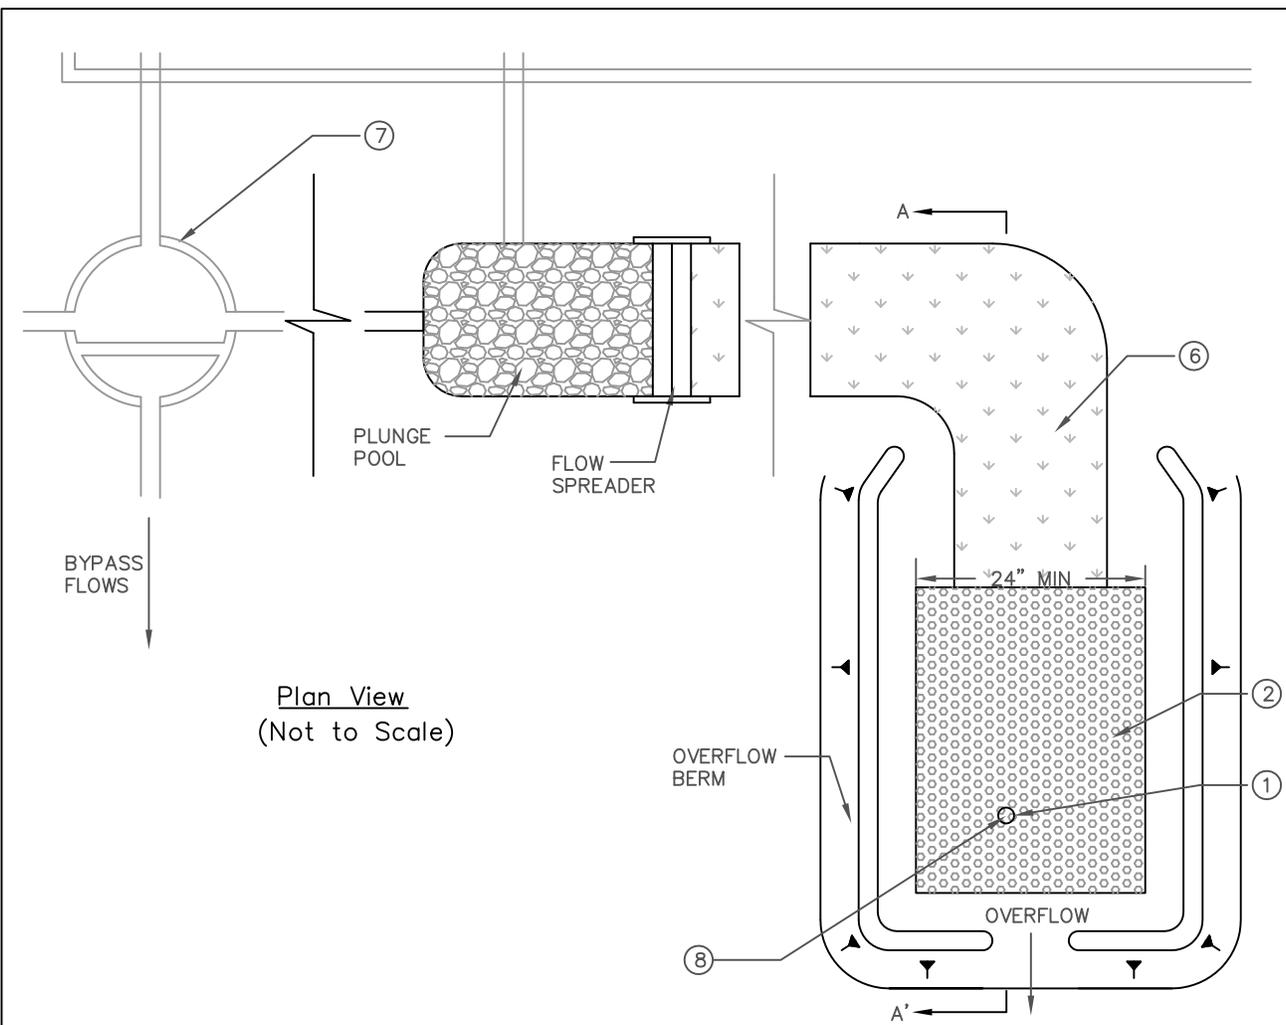

<http://stormwater.wordpress.com/2007/05/23/infiltration--trenches/>

Application

- Open areas adjacent to parking lots, driveways, and buildings
- Roadway medians and shoulders

Routine Maintenance

- Removal trash, debris, and sediment at inlet and outlets
- Wet weather inspection to ensure drain time
- Remove weeds
- Inspect for mosquito breeding

NOTES:

- ① OBSERVATION WELL WITH LOCKABLE ABOVE-GROUND CAP.
- ② 2" PEA GRAVEL FILTER LAYER.
- ③ MINIMUM 10' ABOVE SEASONAL HIGH GROUNDWATER TABLE AND 3' ABOVE BEDROCK.
- ④ 3' - 5' DEEP TRENCH FILLED WITH 2" - 6" DIAMETER CLEAN STONE WITH 30% - 40% VOIDS.
- ⑤ 6" DEEP SAND FILTER LAYER (OR FABRIC EQUIVALENT).
- ⑥ RUNOFF FILTERS THROUGH GRASS FILTER STRIP OR VEGETATED SWALE.
- ⑦ OPTIONAL FLOW CONTROL DEVICE FOR OFF-LINE CONFIGURATIONS.

Figure 6-3: Infiltration Trench

Limitations

The following limitations should be considered before choosing to use an infiltration trench:

- Native soil infiltration rate – soil permeability at the infiltration trench location must be at least 0.5 inches per hour.
- Depth to groundwater, bedrock, or low permeability soil layer – 5 feet vertical separation is required between the bottom of the infiltration trench and the seasonal high groundwater level or mounded groundwater level, bedrock, or other barrier to infiltration to ensure that the facility will completely drain between storms and that infiltrating water will receive adequate treatment through the soils before it reaches the groundwater.
- Slope stability - infiltration BMPs must be sited at least 50 feet away from slopes steeper than 15 percent or an alternative setback established by the geotechnical expert for the project.
- Setbacks - a minimum setback (100 feet or more) must be provided between infiltration BMPs and potable wells, non-potable wells, drain fields and springs. Infiltration BMPs must be setback from building foundations at least eight feet or an alternative setback established by the geotechnical expert for the project.
- Groundwater contamination - the application of infiltration BMPs should include significant pretreatment in an area identified as an unconfined aquifer to ensure groundwater is protected for pollutants of concern.
 - Contaminated soils or groundwater plumes - infiltration BMPs are not allowed at locations with contaminated soils or groundwater where the pollutants could be mobilized or exacerbated by infiltration, unless a site-specific analysis determines that infiltration would be beneficial.
- High pollutant land uses - infiltration BMPs should not be placed in high-risk areas such as at or near service/gas stations, truck stops, and heavy industrial sites due to the groundwater contamination risk unless a site-specific evaluation demonstrates that sufficient pretreatment is provided to address pollutants of concern, high risks areas are isolated from stormwater runoff, or infiltration areas have little chance of spill migration.
- High sediment loading rates – infiltration BMPs may clog quickly if sediment loads are high (e.g., unstabilized site) or if flows are not adequately pretreated.

Design Criteria

The main challenge associated with infiltration trenches is preventing system clogging and subsequent infiltration inhibition. Infiltration trenches should be designed according to the requirements listed in Table 6-5 and outlined in the section below. BMP sizing worksheets are presented in Appendix E.

Table 6-5: Infiltration Trench Design Criteria

Design Parameter	Unit	Design Criteria
Stormwater quality design volume (SQDV)	acre-feet	See Section 2 and Appendix E for calculating SQDV.
Design drawdown time	hr	12 – 72, see Appendix D, Section D.2
Trench bottom elevation	feet	5 feet from seasonally high groundwater table
Setbacks	feet	100 feet from wells, fields, springs Geotechnical expert should establish the setback requirement from building foundations that must be ≥ 8 ft Do not locate under tree drip-lines
Pretreatment	-	BIO-3: Vegetated Swale , BIO-4: Filter Strip , proprietary device, or sedimentation forebay, for all surfaces other than roofs
Design percolation rate, (P_{design})	in/hr	Measured percolation rate must be corrected based onsite suitability assessment and design related considerations described in this fact sheet
Maximum depth of facility (d_{max})	feet	8.0; Defined by the design infiltration rate and the design drawdown time (includes ponding depth and depth of media)
Surface area of facility (A)	square feet	Based on depth of ponding (if applicable) and depth of trench media
Facility geometry	-	Minimum 24 inches wide and maximum 5 feet deep; max 3% bottom slope
Filter media diameter	inches	1 – 3 (gravel); prefabricated media may also be used
Trench lining material	-	Geotextile fabric
Overflow device	-	Required if system is on-line

Geotechnical Considerations

An extensive geotechnical site investigation must be undertaken early in the site planning process to verify site suitability for the installation of infiltration facilities due to the potential to contaminate groundwater, cause slope instability, impact surrounding structures, and have insufficient infiltration capacity. Soil infiltration rates and the water table depth should be evaluated to ensure that conditions are satisfactory for proper operation of an infiltration facility. See Appendix C for guidance on infiltration testing.

The project designer must demonstrate through infiltration testing, soil logs, and the written opinion of a licensed civil engineer that sufficiently permeable soils exist onsite to allow the construction of a properly functioning infiltration facility.

- 1) Infiltration facilities require a minimum soil infiltration rate of 0.5 inches/hour. If infiltration rates exceed 2.4 inches/hour, then the runoff should be fully treated in an upstream BMP prior to infiltration to protect groundwater quality. Pretreatment for coarse sediment removal is required in all instances.
- 2) Groundwater separation must be at least 5 feet from the trench bottom to the measured season high groundwater elevation or estimated high groundwater mounding elevation. Groundwater level measurements must be made during the time when water level is expected to be at a maximum (i.e., toward the end of the wet season).
- 3) Sites with a slope greater than 25% (4:1) should be excluded. A geotechnical analysis and report addressing slope stability are required if located on slopes greater than 15%.

Soil Assessment and Site Geotechnical Investigation Reports

The soil assessment report should:

- State whether the site is suitable for the proposed infiltration trench;
- Recommend a design infiltration rate (see the Step 2 of sizing methodology section, “Determine the design percolation rate,” in the Infiltration Basin fact sheet above);
- Identify the seasonally high depth to groundwater table surface elevation.
- Provide a good understanding of how the stormwater runoff will move in the soil (horizontally or vertically) and if there are any geological conditions that could inhibit the movement of water; and
- If a geotechnical investigation and report are required, the report should:
 - Provide a written opinion by a professional civil engineer describing whether the infiltration trench will compromise slope stability; and

- Identify potential impacts to nearby structural foundations.

Setbacks

- 1) Infiltration facilities shall be setback a minimum of 100 feet from proposed or existing potable wells, non-potable wells, septic drain fields, and springs.
- 2) Infiltration BMPs must be sited at least 50 feet away from slopes steeper than 15 percent or an alternative setback established by the geotechnical expert for the project.
- 3) Infiltration BMPs must be setback from building foundations at least eight feet or an alternative setback established by the geotechnical expert for the project.

Pretreatment

Pretreatment is required for infiltration trenches in order to reduce the sediment load entering the facility and maintain the infiltration rate of the facility. Pretreatment refers to design features that provide settling of large particles before runoff reaches a management practice; easing the long-term maintenance burden. Pretreatment is important for most all structural stormwater BMPs, but it is particularly important for infiltration BMPs. To ensure that pretreatment mechanisms are effective, designers should incorporate sediment reduction practices. Sediment reduction BMPs may include vegetated swales, vegetated filter strips, sedimentation basins or forebays, sedimentation manholes and hydrodynamic separation devices.

For design specification of selected pre-treatment devices, refer to:

- [VEG-3: Vegetated swales](#)
- [VEG-4: Vegetated filter strips](#)
- [TCM-4: Sand filters](#)
- [TCM-5: Cartridge media filters](#)
- [PT-1: Hydrodynamic separation device](#)

Sizing Criteria

See [Sizing Criteria](#) section in the INF-1: Infiltration Basin fact sheet.

Geometry and Sizing

- 1) Infiltration trenches should be at least 2 feet wide and 3 to 5 feet deep.
- 2) The longitudinal slope of the trench should not exceed 3%.
- 3) The filter bed media layers should have the following composition and thickness:

- a. Top layer – If stormwater runoff enters the top of the trench via sheet flow at the ground surface, then the top 2 inches should be pea gravel with a thin 2 to 4 inch layer of pure sand and 2 inch layer of choking stone (e.g., #8) to capture sediment before entering the trench. If stormwater runoff enters the trench from an underground pipe, pretreatment prior to entry into the trench is required.
 - b. Middle layer (3 to 5 feet of washed, 1.5 to 3 inch gravel). Void space should be in the range of 30 percent to 40 percent.
 - c. Bottom layer (6 inches of clean, washed sand to encourage drainage and prevent compaction of the native soil while the stone aggregate is added).
- 4) One or more observation wells should be installed, depending on trench length, to check for water level, drawdown time, and evidence of clogging. A typical observation well consists of a slotted PVC well screen, 4 to 6 inches in diameter, capped with a lockable, above-ground lid.

Drainage

- 1) The bottom of the infiltration bed must be native soil, over-excavated to at least one foot in depth and replaced uniformly without compaction. Amending the excavated soil with 2 to 4 inches (~15% to 30%) of coarse sand is recommended.
- 2) The hydraulic conductivity of the subsurface layers should be sufficient to ensure the design drawdown time. An observation well should be incorporated to allow observation of drain time.

Emergency Overflow

- 1) There must be an overflow route for stormwater flows that overtop the facility or in case the infiltration facility becomes clogged.
- 2) The overflow channel must be able to safely convey flows from the peak design storm to the downstream stormwater conveyance system or other acceptable discharge point.

Vegetation

- 1) Trees and other large vegetation should be planted away from trenches such that drip lines do not overhang infiltration beds.

Maintenance Access

- 1) The facility and outlet structures must all be safely accessible during wet and dry weather conditions.
- 2) An access road along the length of the trench is required, unless the trench is located along an existing road or parking lot that can be safely used for maintenance access.

- 3) If the infiltration trench becomes plugged and fails, then access is needed to excavate the facility to remove and replace the top layer or the filter bed media, as well as to increase all dimensions of the facility by 2 inches to provide a fresh surface for infiltration. To prevent damage and compaction, access must be able to accommodate a backhoe working at “arms length”.

Construction Considerations

To preserve and avoid the loss of infiltration capacity, the following construction guidelines are specified:

- 1) The entire area draining to the facility must be stabilized before construction begins. If this is impossible, a diversion berm should be placed around the perimeter of the infiltration site to prevent sediment entering during construction.
- 2) Infiltration trenches should not be hydraulically connected to the stormwater conveyance system until all contributing tributary areas are stabilized as shown on the Contract Plans and to the satisfaction of the Engineer. Infiltration trenches should not be used as sediment control facilities.
- 3) Compaction of the subgrade with heavy equipment should be minimized to the maximum extent possible. If the use of heavy equipment on the base of the facility cannot be avoided, the infiltrative capacity should be restored by tilling or aerating prior to placing the infiltrative bed.
- 4) The exposed soils should be inspected by a civil engineer after excavation to confirm that soil conditions are suitable.

Operations and Maintenance

Infiltration facility maintenance should include frequent inspections to ensure that water infiltrates into the subsurface completely within the design drawdown time after a storm.

Maintenance and regular inspections are of primary importance if infiltration trenches are to continue to function as originally designed. A specific maintenance plan shall be developed specific to each facility outlining the schedule and scope of maintenance operations, as well as the documentation and reporting requirements. The following are general maintenance requirements:

- 1) Regular inspection should determine if the sediment pretreatment structures require preventative maintenance. Inspect a minimum of twice a year, before and after the rainy season, after large storms, or more frequently if needed.
- 2) If water is noticed in the observation well of the infiltration trench more than 72 hours after a major storm, the infiltration trench may be clogged. Maintenance activities triggered by a potentially clogged facility include:

- a. For trenches, assess the condition of the top aggregate layer for sediment buildup and crusting. Remove top layer of pea gravel and replace. If slow draining conditions persist, entire trench may need to be excavated and replaced.
- 3) Any debris or algae growth located on top of the infiltration facility should be removed and disposed of properly.
- 4) Inspect a minimum of twice a year, before and after the rainy season, after large storms, or more frequently if needed.
- 5) Clean when loss of infiltrative capacity is observed. If drawdown time is observed to have increased significantly over the design drawdown time, removal of sediment may be necessary. This is an expensive maintenance activity and the need for it can be minimized through prevention of upstream erosion.
- 6) Mow as appropriate for vegetative cover species.
- 7) Monitor health of vegetation and replace as necessary.
- 8) Control mosquitoes as necessary.
- 9) Remove litter and debris from trench area as required.

INF-3: Bioretention

Bioretention stormwater treatment facilities are landscaped shallow depressions that capture and filter stormwater runoff. These facilities function as a soil and plant-based filtration device that removes pollutants through a variety of physical, biological, and chemical treatment processes. The facilities normally consist of a ponding area, mulch layer, planting soils, and plantings. An optional gravel layer can be added below the planting soil to provide additional storage volume for infiltration. As stormwater passes down through the planting soil, pollutants are filtered, adsorbed, and biodegraded by the soil and plants. For areas with low permeability native soils or steep slopes, see section [INF-7: Bioinfiltration](#) or [BIO-1: Bioretention with Underdrain](#) for relevant design specifications.

Bioretention in Parkway and parking lots

Photo Credits: Geosyntec Consultants

Application

- Commercial, residential, mixed use, institutional, and recreational uses
- Parking lot islands, traffic circles
- Road parkways & medians

Preventative Maintenance

- Repair small eroded areas
- Remove trash and debris and rake surface soils
- Remove accumulated fine sediments, dead leaves and trash
- Remove weeds and prune back excess plant growth
- Remove sediment and debris accumulation near inlet and outlet structures
- Periodically observe function under wet weather conditions

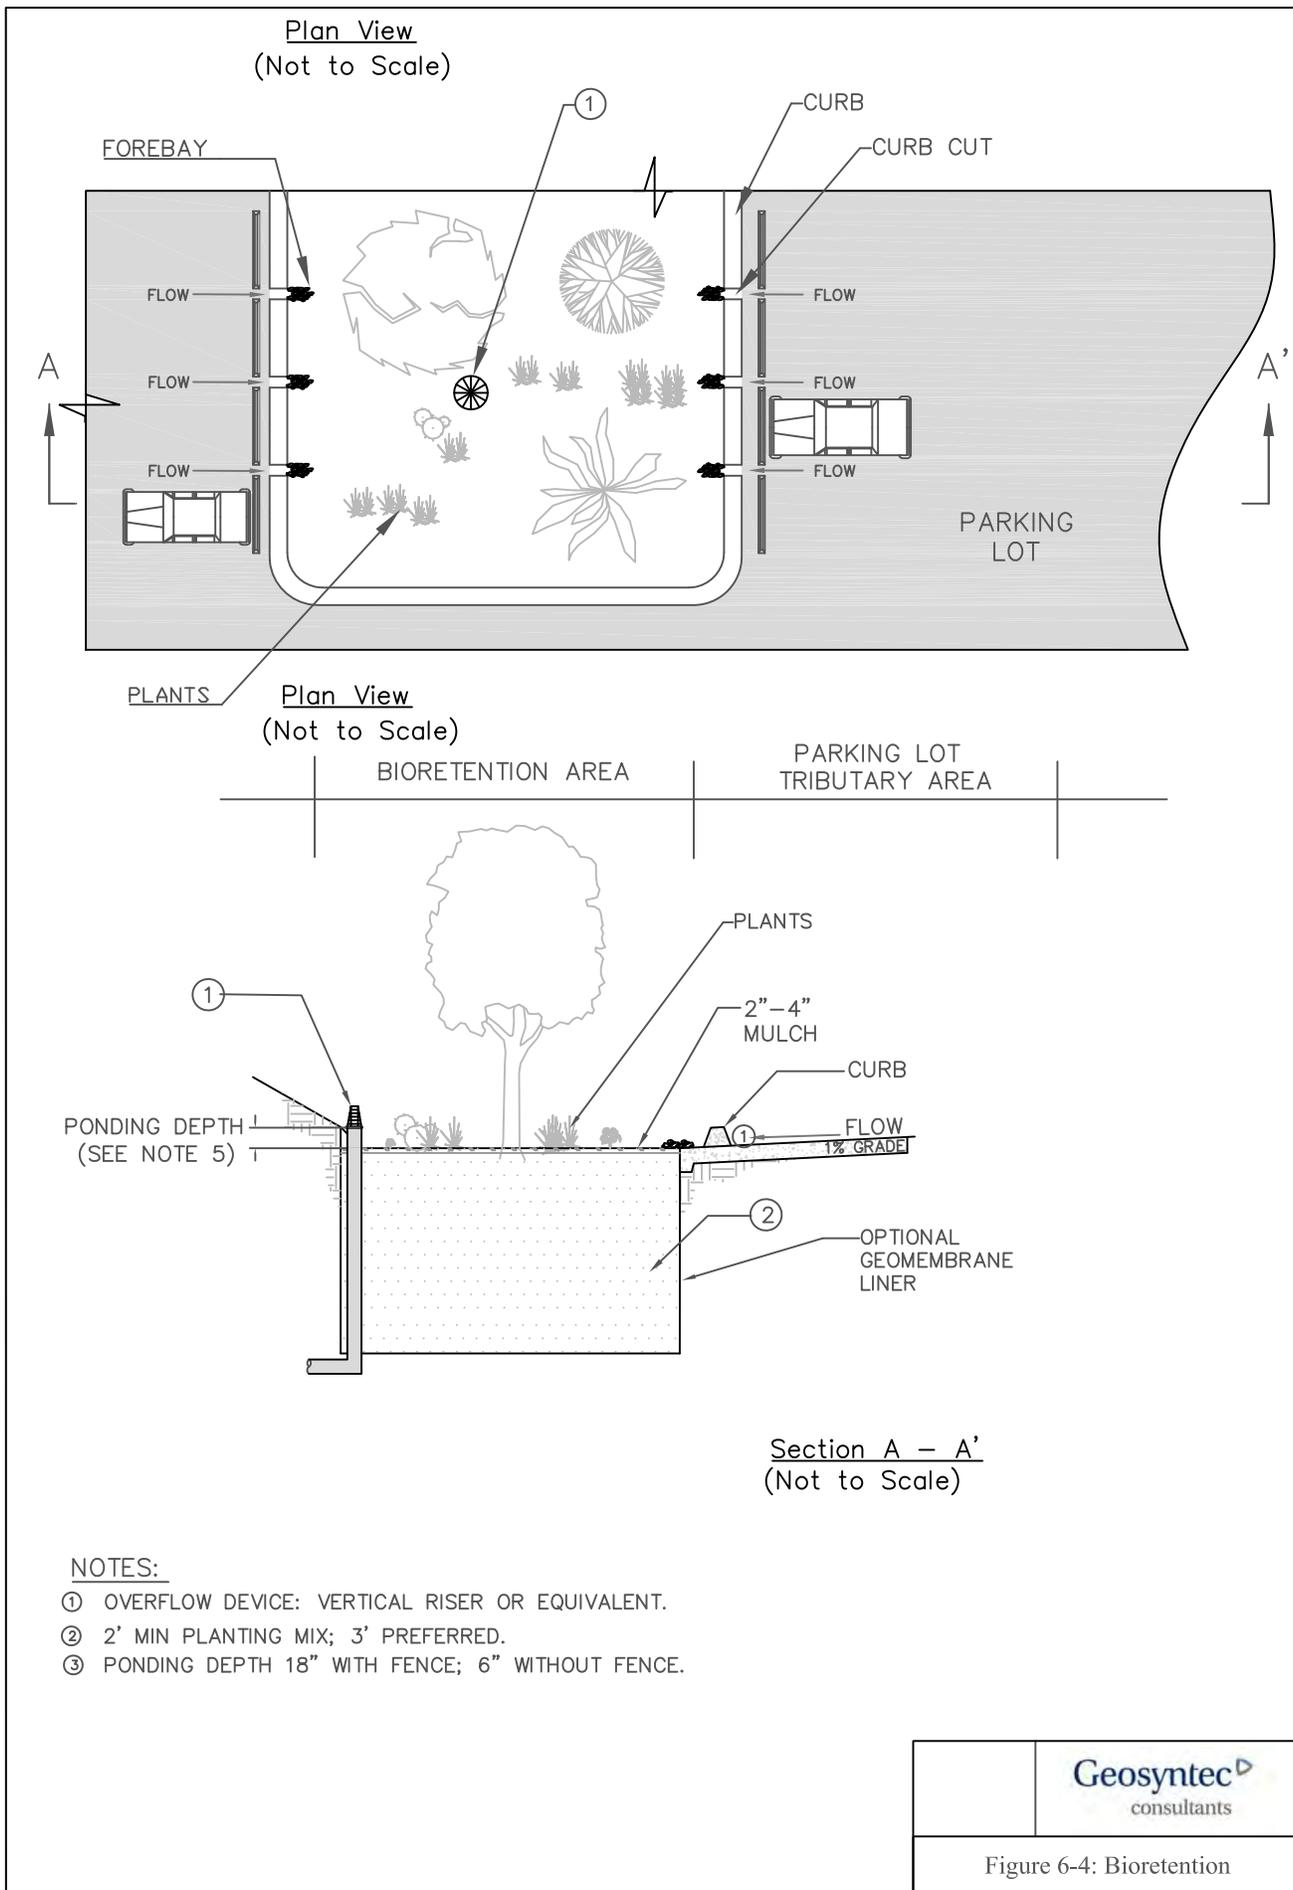

Figure 6-4: Bioretention

Limitations

The following limitations should be considered before choosing to use bioretention:

- 1) Native soil infiltration rate - soil permeability at the bioretention location must be at least 0.5 inches per hour.
- 2) Depth to groundwater, bedrock, or low permeability soil layer – 5 feet vertical separation is required between the bottom of the infiltration trench and the seasonal high groundwater level or mounded groundwater level, bedrock, or other barrier to infiltration to ensure that the facility will completely drain between storms and that infiltrating water will receive adequate treatment through the soils before it reaches the groundwater.
- 3) Slope stability - infiltration BMPs must be sited at least 50 feet away from slopes steeper than 15 percent or an alternative setback established by the geotechnical expert for the project.
- 4) Setbacks - a minimum setback (100 feet or more) must be provided between infiltration BMPs and potable wells, non-potable wells, drain fields, and springs. Infiltration BMPs must be setback from building foundations at least eight feet or have an alternative setback established by the geotechnical expert for the project.
- 5) Groundwater contamination - the application of infiltration BMPs should include significant pretreatment in an area identified as an unconfined aquifer to ensure groundwater is protected for pollutants of concern.
- 6) Contaminated soils or groundwater plumes - infiltration BMPs are not allowed at locations with contaminated soils or groundwater where the pollutants could be mobilized or exacerbated by infiltration, unless a site-specific analysis determines that infiltration would be beneficial.
- 7) High pollutant land uses - infiltration BMPs should not be placed in high-risk areas such as at or near service/gas stations, truck stops, and heavy industrial sites due to the groundwater contamination risk unless a site-specific evaluation demonstrates that sufficient pretreatment is provided to address pollutants of concern, high risk areas are isolated from stormwater runoff, or infiltration areas have little chance of spill migration.
- 8) High sediment loading rates – infiltration BMPs may clog quickly if sediment loads are high (e.g., unstabilized site) or if flows are not adequately pretreated.
- 9) Vertical relief and proximity to storm drain - site must have adequate relief between the land surface and storm drain to permit vertical percolation through the soil media and collection.

Design Criteria

Bioretention should be designed according to the requirements listed in Table 6-6 and outlined in the section below. BMP sizing worksheets are presented in Appendix E.

Table 6-6: Bioretention Design Criteria

Design Parameter	Unit	Design Criteria
Stormwater quality design volume (SQDV)	acre-feet	See Section 2 and Appendix E for calculating SQDV.
Forebay	-	Forebay should be provided for all tributary surfaces that contain landscaped areas. Forebays should be designed to prevent standing water during dry weather and should be planted with a plant palette that is tolerant of wet conditions.
Maximum drawdown time of water ponded on surface	hours	48
Maximum drawdown time of surface ponding plus subsurface pores	hours	96 (72 preferred)
Maximum ponding depth	inches	18
Minimum thickness of amended soil	feet	2 (3 preferred)
Minimum thickness of stabilized mulch	inches	2 to 3
Planting mix composition	-	60 to 80% fine sand, 20 to 40% compost
Overflow device	-	Required

Sizing Criteria

Bioretention facilities can be sized using one of two methods: a simple sizing method or a routing modeling method. With either method the SQDV volume must be completely infiltrated within 96 hours (including subsurface pore space), and surface ponding must be infiltrated within 48 hours. The simple sizing procedure is provided below. For the routing modeling method, refer to [TCM-4 Sand Filters](#).

Step 1: Calculate the Design Volume

Bioretention facilities shall be sized to capture and infiltrate the SQDV volume (see Section 2.3 and Appendix E).

Step 2: Determine the Design Percolation Rate

The percolation rate through the BMP and to the subsurface will decline between maintenance cycles as the surface becomes occluded and particulates accumulate in the infiltration layer. Monitoring of actual facility performance has shown that the full-scale infiltration rate is far lower than the rate measured by small-scale testing. It is important that adequate conservatism is incorporated in the selection of design percolation rates. For bioretention facilities, the design percolation rate discussed here is the adjusted percolation rate of the underlying soils and not the percolation rate of the filter media bed.

Considerations for Design Percolation Rate Corrections

Suitability assessment-related considerations include (Table 6-7):

- Soil assessment methods – the site assessment extent (e.g., number of borings, test pits, etc.) and the measurement method used to estimate the short-term infiltration rate.
- Predominant soil texture/percent fines – soil texture and the percent of fines can greatly influence the potential for clogging.
- Site soil variability – site with spatially heterogeneous soils (vertically or horizontally) as determined from site investigations are more difficult to estimate average properties, resulting in a higher level of uncertainty associated with initial estimates.
- Depth to seasonal high groundwater/impervious layer – groundwater mounding may become an issue during excessively wet conditions where shallow aquifers or shallow clay lenses are present.

Localized infiltration testing refers to methods such as the double ring infiltrometer test (ASTM D3385-88), which measure infiltration rates over an area less than 10 sq-ft and do not attempt to account for soil heterogeneity. Extensive infiltration testing refers to methods that include excavating a significant portion of the proposed infiltration area, filling the excavation with water, and monitoring drawdown. In all cases, testing should be conducted in the area of the proposed BMP where, based on geotechnical data, soils appear least likely to support infiltration.

Table 6-7: Suitability Assessment Related Considerations for Infiltration Facility Safety Factors

Consideration	High Concern	Medium Concern	Low Concern
Assessment methods	Use of soil survey maps or simple texture analysis to estimate short-term infiltration rates	Direct measurement of ≥ 20 percent of infiltration area with localized infiltration measurement methods (e.g., infiltrometer)	Direct measurement of ≥ 50 percent of infiltration area with localized infiltration measurement methods or Use of extensive test pit infiltration measurement methods
Ventura Hydrology Manual soil number (measured infiltration rate)	3 ($f = 0.5 - 0.64$)	4 or 5 ($f = 0.65 - 0.91$)	6 or 7 ($f = 0.92$ or higher)
Site soil variability	Highly variable soils indicated from site assessment or limited soil borings collected during site assessment	Soil borings/test pits indicate moderately homogeneous soils	Multiple soil borings/test pits indicate relatively homogeneous soils
Depth to groundwater/impervious layer	<10 ft below facility bottom	10-30 ft below facility bottom	>30 below facility bottom

Design related considerations include:

- Size of area tributary to facility – all things being equal, both physical and economic risk factors related to infiltration facilities increase with an increase in the tributary area served. Therefore facilities serving larger tributary areas should use more restrictive adjustment factors.
- Level of pretreatment/expected influent sediment loads – credit should be given for good pretreatment by allowing less restrictive factors to account for the reduced probability of clogging from high sediment loading. Also, facilities designed to capture runoff from relatively clean surfaces such as rooftops are likely to see low sediment loads and therefore should be allowed to apply less restrictive safety factors.
- Redundancy – facilities that consist of multiple subsystems operating in parallel such that parts of the system remain functional when other parts fail and/or bypass should be rewarded for the built-in redundancy with less restrictive

correction and safety factors. For example, if bypass flows would be at least partially treated in another BMP, the risk of discharging untreated runoff in the event of clogging the primary facility is reduced. A bioretention facility that overflows to a landscaped area is another example.

- Compaction during construction – proper construction oversight is needed during construction to ensure that the bottoms of bioretention facility are not overly compacted. Facilities that do not commit to proper construction practices and oversight should have to use more restrictive correction and safety factors.

Table 6-8: Design Related Considerations for Infiltration Facility Safety Factors

Consideration	High Concern	Medium Concern	Low Concern
Tributary area size	Greater than 10 acres.	Greater than 2 acres but less than 10 acres.	2 acres or less.
Level of pre-treatment/ expected influent sediment loads	Pre-treatment from gross solids removal devices only, such as hydrodynamic separators, racks and screens, AND tributary area includes landscaped areas, steep slopes, high traffic areas, or any other areas expected to produce high sediment, trash, or debris loads.	Good pre-treatment with BMPs that mitigate coarse sediments such as vegetated swales AND influent sediment loads from the tributary area are expected to be relatively low (e.g., low traffic, mild slopes, disconnected impervious areas, etc.).	Excellent pre-treatment with BMPs that mitigate fine sediments such as bioretention or media filtration OR sedimentation or facility only treats runoff from relatively clean surfaces, such as rooftops.
Redundancy of treatment	No redundancy in BMP treatment train.	Medium redundancy, other BMPs available in treatment train to maintain at least 50% of function of facility in event of failure.	High redundancy, multiple components capable of operating independently and in parallel, maintaining at least 90% of facility functionality in event of failure.
Compaction during construction	Construction of facility on a compacted site or elevated probability of unintended/ indirect compaction.	Medium probability of unintended/ indirect compaction.	Heavy equipment actively prohibited from infiltration areas during construction and low probability of unintended/ indirect compaction.

Adjust the measured short-term infiltration rate using a weighted average of several safety factors using the worksheet shown in Table 6-9 below. The design percolation rate would be determined as follows:

- For each consideration shown in Tables 6-7 and 6-8 above, determine whether the consideration is a high, medium, or low concern.
- For all high concerns assign a factor value of 3, for medium concerns assign a factor value of 2, and for low concerns assign a factor value of 1.
- Multiply each of the factors by the corresponding weight to get a product.
- Sum the products within each factor category to obtain a safety factor for each.
- Multiply the two safety factors together to get the final combined safety factor. If the combined safety factor is less than 2, then use 2 as the safety factor.
- Divide the measured short-term infiltration rate by the combined safety factor to obtain the adjusted design percolation rate for use in sizing the infiltration facility.

Table 6-9: Infiltration Facility Safety Factor Determination Worksheet

Factor Category		Factor Description	Assigned Weight (w)	Factor Value (v)	Product (p) p = w x v
A	Suitability Assessment	Soil assessment methods	0.25		
		Predominant soil texture	0.25		
		Site soil variability	0.25		
		Depth to groundwater / impervious layer	0.25		
		Suitability Assessment Safety Factor, $S_A = \sum p$			
B	Design	Tributary area size	0.25		
		Level of pre-treatment/ expected sediment loads	0.25		
		Redundancy	0.25		
		Compaction during construction	0.25		
		Design Safety Factor, $S_B = \sum p$			
Combined Safety Factor = $S_A \times S_B$					

Note: The minimum combined adjustment factor shall not be less than 2.0 and the maximum combined adjustment factor shall not exceed 9.

Step 3: Calculate the surface area

Determine the size of the required infiltrating surface by assuming the SQDV will fill the available ponding depth plus the void spaces in the media, based on the computed porosity of the filter media and optional aggregate layer.

- 1) Determine the maximum depth of surface ponding that can be infiltrated within the required surface drain time (48 hr), (d_{max}), as follows:

$$d_{max} = \frac{P_{design} \times t_{ponding}}{12 \frac{in}{ft}} \quad (\text{Equation 6-6})$$

Where:

- $t_{ponding}$ = required drain time of surface ponding (48 hrs)
- P_{design} = design percolation rate of underlying soils (in/hr) (see Step 2, above)
- d_{max} = the maximum depth of surface ponding water that can be infiltrated within the required drain time (ft), calculated using Equation 6-6

- 2) Choose surface ponding depth (d_p) such that:

$$d_p \leq d_{max} \quad (\text{Equation 6-7})$$

Where:

- d_p = selected surface ponding depth (ft)
- d_{max} = the maximum depth of water that can be infiltrated within the required drain time (ft)

Choose thickness(es) of amended media and optional gravel storage layer and calculate total effective storage depth of the bioretention area ($d_{effective}$), as follows:

$$d_{effective} \leq (d_p + n_{media}^* l_{media} + n_{gravel} l_{gravel}) \quad (\text{Equation 6-8})$$

Where:

- $d_{effective}$ = total equivalent depth of water stored in bioretention area (ft), including surface ponding and volume available in pore spaces of media and gravel layers
- d_p = surface ponding depth (ft), chosen using Equation 6-7
- n_{media}^* = available porosity of amended soil media (ft/ft), approximately 0.25 ft/ft accounting for antecedent moisture conditions. This represents the volume of

available pore space as a fraction of the total soil volume; sometimes has units of (ft³/ft³) or described as a percentage.

l_{media} = thickness of amended soil media layer (ft), minimum 2 ft

n_{gravel} = porosity of optional gravel layer (ft/ft), approximately 0.40 ft/ft

l_{gravel} = thickness of optional gravel layer (ft)

- 3) Check that entire effective depth (surface plus subsurface storage), $d_{effective}$, infiltrates in no greater than 96 hours as follows:

$$t_{total} = \frac{d_{effective}}{P_{design}} \times 12 \frac{in}{ft} \leq 96 \text{ hr} \quad (\text{Equation 6-9})$$

Where:

$d_{effective}$ = total equivalent depth of water stored in bioretention area (ft), calculated using Equation 6-8

P_{design} = design percolation rate of underlying soils (in/hr) (see Step 2, above)

If $t_{total} > 96$ hrs, then reduce surface ponding depth and/or amended media thickness and/or gravel thickness and return to 1).

If $t_{total} \leq 96$ hrs, then proceed to 5).

- 4) Calculate required infiltrating surface area, (A_{req}):

$$A_{req} = \frac{SQDV}{d_{effective}} \quad (\text{Equation 6-10})$$

Where:

A_{req} = required infiltrating area (ft²). Should be calculated at the contour corresponding to the mid ponding depth (i.e., $0.5 \times d_p$ from the bottom of the facility).

$SQDV$ = stormwater quality design volume (ft³)

$d_{effective}$ = total equivalent depth of water stored in bioretention area (ft), calculated using Equation 6-8

- 5) Calculate total footprint required by including a buffer for side slopes and freeboard; A_{req} is calculated at the contour corresponding to the mid ponding depth (i.e., $0.5 \times d_p$ from the bottom of the facility).

Geometry

- 1) Bioretention areas shall be sized to capture and treat the stormwater quality design volume (See Section 2 and Appendix E for calculating SQDV) with an 18-inch maximum ponding depth. *The intention is that ponding depth be limited to a depth that will allow for a health vegetation layer.*
- 2) Minimum planting soil depth should be 2 feet, although 3 feet is preferred. *The intention is that the minimum planting soil depth should provide a beneficial root zone for the chosen plant palette and adequate water storage for the SQDV.*
- 3) A gravel storage layer below the bioretention soil media to promote infiltration into the native soil is optional.
- 4) Bioretention should be designed to drain below the planting soil in less than 48 hours and completely drain in less than 96 hours. *The intention is that soils must be allowed to dry out periodically in order to restore hydraulic capacity needed to receive flows from subsequent storms, maintain infiltration rates, maintain adequate soil oxygen levels for healthy soil biota and vegetation, and to provide proper soil conditions for biodegradation and retention of pollutants.*

Flow Entrance and Energy Dissipation

The following types of flow entrance can be used for bioretention cells:

- 1) Dispersed, low velocity flow across a landscape area. Dispersed flow may not be possible given space limitations or if the facility is controlling roadway or parking lot flows where curbs are mandatory.
- 2) Dispersed flow across pavement or gravel and past wheel stops for parking areas.
- 3) Curb cuts for roadside or parking lot areas: curb cuts should include rock or other erosion protection material in the channel entrance to dissipate energy. Flow entrance should drop 2 to 3 inches from curb line and it should provide a settling area and periodic sediment removal of coarse material before flow dissipates to the remainder of the cell.
- 4) Pipe flow entrance: Piped entrances, such as roof downspouts, should include rock, splash blocks, or other appropriate measures at the entrance to dissipate energy and disperse flows.

Woody plants (trees, shrubs, etc.) can restrict or concentrate flows and can be damaged by erosion around the root ball and should not be placed directly in the entrance flow path.

Overflow

An overflow device is required at the 18-inch ponding depth. The following, or equivalent should be provided:

- 1) A vertical PVC pipe (SDR 35) to act as an overflow riser.
- 2) The overflow riser(s) should be 6 inches or greater in diameter, so it can be cleaned without damage to the pipe.

The inlet to the riser should be at the ponding depth (18 inches for fenced bioretention areas and 6 inches for areas that are not fenced), and be capped with a spider cap to exclude floating mulch and debris. Spider caps should be screwed in or glued, i.e., not removable.

Hydraulic Restriction Layers

Infiltration pathways may need to be restricted due to the close proximity of roads, foundations, or other infrastructure. A geomembrane liner, or other equivalent water proofing, may be placed along the vertical walls to reduce lateral flows. This liner should have a minimum thickness of 30 mils.

Planting/Storage Media

- 1) The planting media placed in the cell should achieve a long-term, in-place infiltration rate of at least 1 inch per hour. Higher infiltration rates are permissible. If the design long-term, in-place infiltration rate of the soil exceeds 12 inches per hour, documentation should be provided to demonstrate that the media will adequately address pollutants of concern at a higher flowrate. Bioretention soil shall also support vigorous plant growth.
- 2) Planting media should consist of 60 to 80% fine sand and 20 to 40% compost.
- 3) Sand should be free of wood, waste, coating such as clay, stone dust, carbonate, etc., or any other deleterious material. All aggregate passing the No. 200 sieve size should be non-plastic. Sand for bioretention should be analyzed by an accredited lab using #200, #100, #40, #30, #16, #8, #4, and 3/8 sieves (ASTM D 422 or as approved by the local permitting authority) and meet the following gradation (Note: all sands complying with ASTM C33 for fine aggregate comply with the gradation requirements below):

Sieve Size (ASTM D422)	% Passing (by weight)	
	Minimum	Maximum
3/8 inch	100	100
#4	90	100
#8	70	100
#16	40	95
#30	15	70
#40	5	55
#100	0	15
#200	0	5

Note: the gradation of the sand component of the media is believed to be a major factor in the hydraulic conductivity of the media mix. If the desired hydraulic conductivity of the media cannot be achieved within the specified proportions of sand and compost (#2), then it may be necessary to utilize sand at the coarser end of the range specified in above (“minimum” column).

- 4) Compost should be a well decomposed, stable, weed free organic matter source derived from waste materials including yard debris, wood wastes, or other organic materials not including manure or biosolids meeting standards developed by the US Composting Council (USCC). The product shall be certified through the USCC Seal of Testing Assurance (STA) Program (a compost testing and information disclosure program). Compost quality should be verified via a lab analysis to be:
- Feedstock materials shall be specified and include one or more of the following: landscape/yard trimmings, grass clippings, food scraps, and agricultural crop residues.
 - Organic matter: 35-75% dry weight basis.
 - Carbon and Nitrogen Ratio: 15:1 < C:N < 25:1
 - Maturity/Stability: shall have dark brown color and a soil-like odor. Compost exhibiting a sour or putrid smell, containing recognizable grass or leaves, or is hot (120 F) upon delivery or rewetting is not acceptable.
 - Toxicity: any one of the following measures is sufficient to indicate non-toxicity:
 - $\text{NH}_4:\text{NH}_3 < 3$
 - Ammonium < 500 ppm, dry weight basis
 - Seed Germination > 80% of control
 - Plant trials > 80% of control

- Solvita® > 5 index value
- Nutrient content:
 - Total Nitrogen content 0.9% or above preferred
 - Total Boron should be <80 ppm, soluble boron < 2.5 ppm
- Salinity: < 6.0 mmhos/cm
- pH between 6.5 and 8 (may vary with plant palette)

Compost for bioretention should be analyzed by an accredited lab using #200, ¼ inch, ½ inch, and 1 inch sieves (ASTM D 422 or as approved by the local permitting authority) and meet the following gradation:

Sieve Size (ASTM D422)	% Passing (by weight)	
	Minimum	Maximum
1 inch	99	100
½ inch	90	100
¼ inch	40	90
#200	2	10

Tests should be sufficiently recent to represent the actual material that is anticipated to be delivered to the site. If processes or sources used by the supplier have changed significantly since the most recent testing, new tests should be requested.

Note: the gradation of compost used in bioretention media is believed to play an important role in the saturated hydraulic conductivity of the media. To achieve a higher saturated hydraulic conductivity, it may be necessary to utilize compost at the coarser end of this range (“minimum” column). The percent passing the #200 sieve (fines) is believed to be the most important factor in hydraulic conductivity.

In addition, a coarser compost mix provides more heterogeneity of the bioretention media, which is believed to be advantageous for more rapid development of soil structure needed to support health biological processes. This may be an advantage for plant establishment with lower nutrient and water input.

- 5) The bioretention area should be covered with 2 to 4 inches (average 3 inches) of mulch at the start and an additional placement of 1 to 2 inches of mulch should be added annually. *The intention is that to help sustain the nutrient levels, suppress weeds, retain moisture, and maintain infiltration capacity.*

Plants

- 1) Plant materials should be tolerant of summer drought, ponding fluctuations, and saturated soil conditions for 48 to 96 hours.

- 2) It is recommended that a minimum of three types of tree, shrubs, and/or herbaceous groundcover species be incorporated to protect against facility failure due to disease and insect infestations of a single species.
- 3) Native plant species and/or hardy cultivars that are not invasive and do not require chemical inputs should be used to the maximum extent practicable.

Operations and Maintenance

Bioretention areas require annual plant, soil, and mulch layer maintenance to ensure optimum infiltration, storage, and pollutant removal capabilities. In general, bioretention maintenance requirements are typical landscape care procedures and include:

- 1) Watering: Plants should be drought-tolerant. Watering may be required during prolonged dry periods after plants are established.
- 2) Erosion control: Inspect flow entrances, ponding area, and surface overflow areas periodically, and replace soil, plant material, and/or mulch layer in areas if erosion has occurred (see Appendix I for a bioretention inspection and maintenance checklist). Properly designed facilities with appropriate flow velocities should not have erosion problems, except perhaps in extreme events. If erosion problems occur, the following should be reassessed: (1) flow velocities and gradients within the cell, and (2) flow dissipation and erosion protection strategies in the pretreatment area and flow entrance. If sediment is deposited in the bioretention area, immediately determine the source within the contributing area, stabilize, and remove excess surface deposits.
- 3) Plant material: Depending on aesthetic requirements, occasional pruning and removing of dead plant material may be necessary. Replace all dead plants and if specific plants have a high mortality rate, assess the cause and, if necessary, replace with more appropriate species. Periodic weeding is necessary until plants are established. The weeding schedule should become less frequent if the appropriate plant species and planting density have been used and, as a result, undesirable plants excluded.
- 4) Nutrients and pesticides: The soil mix and plants should be selected for optimum fertility, plant establishment, and growth. Nutrient and pesticide inputs should not be required and may degrade the pollutant processing capability of the bioretention area, as well as contribute pollutant loads to receiving waters. By design, bioretention facilities are located in areas where phosphorous and nitrogen levels are often elevated and these should not be limiting nutrients. If in question, have soil analyzed for fertility.
- 5) Mulch: Replace mulch annually in bioretention facilities where heavy metal deposition is likely (e.g., contributing areas that include industrial and auto dealer/repair parking lots and roads). In residential lots or other areas where metal

deposition is not a concern, replace or add mulch as needed to maintain a 2 to 3 inch depth at least once every two years.

- 6) Soil: Soil mixes for bioretention facilities are designed to maintain long-term fertility and pollutant processing capability. Estimates from metal attenuation research suggest that metal accumulation should not present an environmental concern for at least 20 years in bioretention systems. Replacing mulch in bioretention facilities where heavy metal deposition is likely provides an additional level of protection for prolonged performance. If in question, have soil analyzed for fertility and pollutant levels.

INF-4: Drywell

A dry well is defined as a bored, drilled, or driven shaft or hole whose depth is greater than its width. A dry well is designed specifically for flood alleviation and stormwater disposal. Drywells are similar to infiltration trenches in their design and function, as they are designed to temporarily store and infiltrate runoff, primarily from rooftops or other impervious areas with low pollutant loading. A dry well may be either a small excavated pit filled with aggregate or a prefabricated storage chamber or pipe segment.

Dry wells can be used to reduce the increased volume of stormwater runoff caused by roofs of buildings. While generally not a significant source of runoff pollution, roofs are one of the most important sources of new or increased runoff volume from land development sites. Dry wells can also be used to indirectly enhance water quality by reducing the amount of SQDV to be treated by the other, downstream stormwater management facilities.

Drywell installation

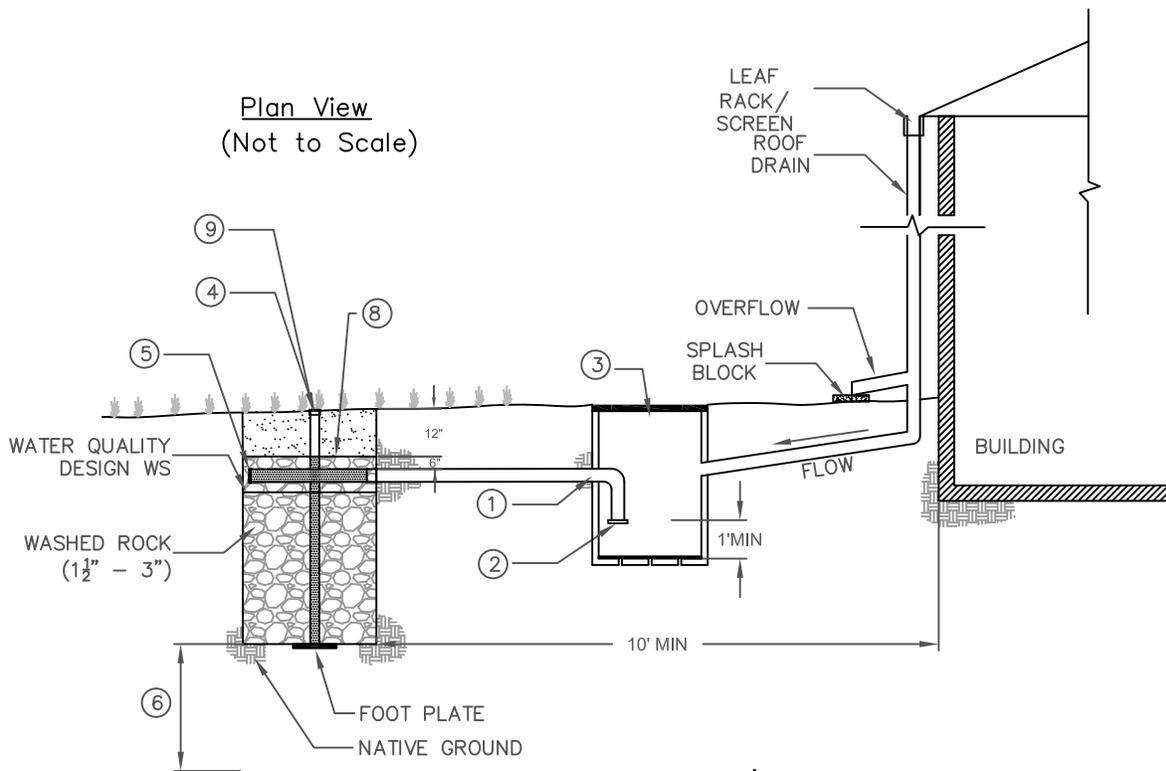

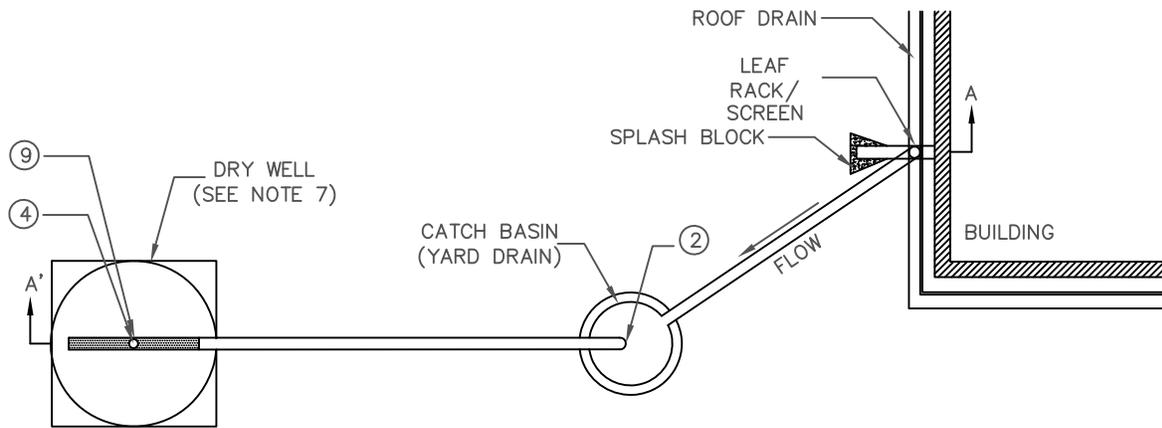

Photo Credits: 1. K&A Enterprises; 2. Canale Landscaping

Application

- Infiltration of roof runoff

Preventative Maintenance

- Remove trash, debris, and sediment at inlet and outlets
- Wet weather inspection to ensure drain time
- Inspect for mosquito breeding

NOTES:

- ① MINIMUM 4" – 6" DIAMETER PVC PIPE. INSTALL AT FLAT SLOPE.
- ② INSTALL FINE MESH SCREEN AT INLET TO DRY WELL. SET INLET ELEVATION AT 1' MINIMUM ABOVE CATCH BASIN BOTTOM.
- ③ CATCH BASIN (YARD DRAIN) INSTALLED WITH A SOLID LID FLUSH WITH GROUND SURFACE.
- ④ 4–6" VERTICAL PERFORATED PVC INSPECTION WELL WITH SCREW LID (NUT DOWN) FLUSH WITH GROUND SURFACE.
- ⑤ CAP END OF 4–6" HORIZONTAL PERFORATED PVC DISPERSION PIPE.
- ⑥ MINIMUM 10' ABOVE SEASONAL HIGH GROUNDWATER TABLE AND 3' ABOVE BEDROCK.
- ⑦ DRY WELL CONFIGURATION MAY VARY (E.G. PRE-FAB MAY BE CIRCULAR).
- ⑧ CHOKING STONE LAYER SHALL BE PLACED ON TOP OF THE DRY WELL TO SEPARATE IT FROM THE TOPSOIL AND PREVENT CLOGGING.

Figure 6-5: Drywell

Limitations

The following limitations shall be considered before choosing to use a dry well:

- Native soil infiltration rate – soil permeability at the infiltration basin location must be at least 0.5 inches per hour.
- Depth to groundwater, bedrock, or low permeability soil layer – 5 feet vertical separation is required between the bottom of the infiltration basin and the seasonal high groundwater level or mounded groundwater level, bedrock, or other barrier to infiltration to ensure that the facility will completely drain between storms and that infiltrating water will receive adequate treatment through the soils before it reaches the groundwater.
- Slope stability - infiltration BMPs must be sited at least 50 feet away from slopes steeper than 15 percent or an alternative setback established by the geotechnical expert for the project.
- Setbacks - a minimum setback (100 feet or more) must be provided between infiltration BMPs and potable wells, non-potable wells, drain fields, and springs. Infiltration BMPs must be setback from building foundations at least eight feet or have an alternative setback established by the geotechnical expert for the project.
- Groundwater contamination - the application of infiltration BMPs should include significant pretreatment in an area identified as an unconfined aquifer, to ensure groundwater is protected from pollutants of concern.
- Contaminated soils or groundwater plumes - infiltration BMPs are not allowed at locations with contaminated soils or groundwater where the pollutants could be mobilized or exacerbated by infiltration, unless a site-specific analysis determines the infiltration would be beneficial.
- High pollutant land uses - infiltration BMPs should not be placed in high-risk areas such as at or near service/gas stations, truck stops, and heavy industrial sites due to groundwater contamination risk unless a site-specific evaluation demonstrates that sufficient pretreatment is provided to address pollutants of concern, high risks areas are isolated from stormwater runoff, or infiltration areas have little chance of spill migration.
- High sediment loading rates – infiltration BMPs may clog quickly if sediment loads are high (e.g., unstabilized site) or if flows are not adequately pretreated.
- Dry wells cannot receive untreated stormwater runoff, except rooftop runoff. Pretreatment of runoff from other surfaces is necessary to prevent premature failure that results from clogging with fine sediment, and to prevent potential groundwater contamination due to nutrients, salts, and hydrocarbons.

- Infiltration structures cannot be used to treat runoff from portions of the site that are not stabilized.
- Rehabilitation of failed dry wells requires complete reconstruction.

Design Criteria

The main challenge associated with drywells, as with infiltration trenches, is the prevention of system clogging and subsequent infiltration inhibition. Drywells should be designed according to the requirements listed in Table 6-10 and outlined in the section below. BMP sizing worksheets are presented in Appendix E.

Table 6-10: Infiltration BMP Design Criteria

Design Parameter	Unit	Design Criteria
Stormwater quality design volume (SQDV)	acre-feet	See Section 2 and Appendix E for calculating SQDV.
Design drawdown time	hour	12
Pretreatment	-	BIO-3: Vegetated Swale , BIO-4: Filter Strip , proprietary device, or equivalent.
Design percolation rate (k_{design})	in/hr	Shall be corrected for testing method, potential for clogging and compaction over time, and facility geometry.
Maximum depth of facility (d_{max})	feet	Defined by the design infiltration rate and the design drawdown time (includes depth of media).
Surface area of facility (A)	ft ²	Based on depth of dry well media.
Facility geometry	-	Geometry varies; max 10 feet deep; flat bottom slope.
Filter media diameter	inches	1.5 – 3 (gravel); prefabricated media may also be used
Overflow device	-	Required if system is on-line

Geotechnical Considerations

An extensive geotechnical site investigation must be undertaken early in the site planning process to verify site suitability for the installation of infiltration facilities, due to the potential to contaminate groundwater, cause slope instability, impact surrounding structures, and have insufficient infiltration capacity. Soil infiltration rates and the water table depth should be evaluated to ensure that conditions are satisfactory for proper operation of an infiltration facility. See Appendix C for guidance on infiltration testing.

The project designer must demonstrate through infiltration testing, soil logs, and the written opinion of a licensed civil engineer that sufficiently permeable soils exist on site to allow the construction of a properly functioning infiltration facility.

- 1) Infiltration facilities require a minimum soil infiltration rate of 0.5 inches/hour. If infiltration rates exceed 2.4 inches/hour, then the runoff should be fully-treated in an upstream BMP prior to infiltration to protect groundwater quality. Pretreatment for coarse sediment removal is required in all instances.
- 2) Groundwater separation must be at least 5 feet from the basin bottom to the measured season high groundwater elevation or estimated high groundwater mounding elevation. Measurements of groundwater levels must be made during the time when water level is expected to be at a maximum (i.e., toward the end of the wet season).
- 3) Sites with a slope greater than 25% (4:1) should be excluded. A geotechnical analysis and report addressing slope stability are required if located on slopes greater than 15%.

Soil Assessment and Site Geotechnical Investigation Reports

The soil assessment report should:

- State whether the site is suitable for the proposed drywell;
- Recommend a design infiltration rate (see the Step 2 of sizing methodology section, “Determine the design percolation rate,” in the INF-1: Infiltration Basin fact sheet above);
- Identify the seasonal high depth to groundwater table surface elevation;
- Provide a good understanding of how the stormwater runoff will move in the soil (horizontally or vertically) and if there are any geological conditions that could inhibit the movement of water; and
- If a geotechnical investigation and report are required, the report should:
 - Provide a written opinion by a professional civil engineer describing whether the drywell will compromise slope stability; and
 - Identify potential impacts to nearby structural foundations.

Setbacks

- 1) Infiltration facilities shall be setback a minimum of 100 feet from proposed or existing potable wells, non-potable wells, septic drain fields, and springs.

- 2) Infiltration BMPs must be sited at least 50 feet away from slopes steeper than 15 percent or an alternative setback established by the geotechnical expert for the project.
- 3) Infiltration BMPs must be setback from building foundations at least eight feet or have an alternative setback established by the geotechnical expert for the project.

Pretreatment

- A removable filter with a screened bottom should be installed in the roof leader below the surcharge pipe in order to screen out leaves and other debris.
- Though roofs are generally not a significant source of runoff pollution, they can still be source of particulates and organic matter. Measures such as roof gutter guards, roof leader clean-out with sump, or an intermediate sump box can provide pretreatment for dry wells by minimizing the amount of sediment and other particulates that may enter it.

Sizing Criteria

See [Sizing Criteria](#) section in the INF-1: Infiltration Basin fact sheet.

Geometry and Sizing

- 1) Dry well configurations vary, but generally they have length and width dimensions closer to square than infiltration trenches. Pre-fabricated dry-wells are often circular. The surface area of the dry well must be large enough to infiltrate the storage volume in 12 hours based on the maximum depth allowable (d_{max}).
- 2) The filter bed media layers are the same as for infiltration trenches unless prefabricated dry wells and/or media are used. The porosity of gravel media systems is generally 30 to 40% and is 80 to 95% for prefabricated media systems.
- 3) If a dry well receives runoff from an underground pipe (i.e., runoff does not enter the top of the dry well from the ground surface), a fine mesh screen should be installed at the inlet. The inlet elevation should be 18 inches below the ground surface (i.e., below 12 inches of surface soil and 6 inches of dry well media).
- 4) An observation well should be installed to check for water levels, drawdown time, and evidence of clogging. A typical observation well consists of a slotted PVC well screen, 4 to 6 inches in diameter, capped with a lockable, above-ground lid.

Drainage

- 1) The bottom of infiltration bed must be native soil, over-excavated to at least one foot in depth and replaced uniformly without compaction. Amending the excavated soil with 2 to 4 inches (~15% to 30%) of coarse sand is recommended.

- 2) The hydraulic conductivity of the subsurface layers should be sufficient to ensure a maximum 12 hr drawdown time. An observation well should be incorporated to allow observation of drain time.

Emergency Overflow

- 1) There must be an overflow route for stormwater flows that overtop the facility or in case the infiltration facility becomes clogged.
- 2) The overflow channel must be able to safely convey flows from the peak design storm to the downstream stormwater conveyance system or other acceptable discharge point.

Vegetation

- 1) Drywells should be kept free of vegetation.
- 2) Trees and other large vegetation should be planted away from drywells such that drip lines do not overhang infiltration beds.

Maintenance Access

- 1) The facility and outlet structures must all be safely accessible during wet and dry weather conditions.
- 2) Maintenance access is required.
- 3) If the drywell becomes plugged and fails, then access is needed to excavate the facility to remove and replace the top layer and the filter bed media of the structure. To prevent damage and compaction, access must be able to accommodate a backhoe working at “arms length”.

Construction Considerations

To preserve and avoid the loss of infiltration capacity, the following construction guidelines should be specified:

- 1) The entire area draining to the facility must be stabilized before construction begins. If this is impossible, a diversion berm should be placed around the perimeter of the infiltration site to prevent sediment entering during construction.
- 2) Drywells should not be hydraulically connected to the stormwater conveyance system until all contributing tributary areas are stabilized as shown on the Contract Plans and to the satisfaction of the Engineer. Drywells should not be used as sediment control facilities.
- 3) Compaction of the subgrade with heavy equipment should be minimized to the maximum extent possible. If the use of heavy equipment on the base of the facility

cannot be avoided, the infiltration capacity should be restored by tilling or aerating prior to placing the infiltrative bed.

- 4) The exposed soils should be inspected by a civil engineer after excavation to confirm that soil conditions are suitable.

Operations and Maintenance

Drywell maintenance should be performed frequently to ensure that water infiltrates into the subsurface completely within the recommended infiltration time (or drain time if a drywell receives runoff from an underground pipe) of 72 hours or less after a storm.

Maintenance and regular inspections are important for the proper function of drywells. A specific maintenance plan shall be developed specifically for each facility outlining the schedule and scope of maintenance operations, documentation, and reporting requirements.

INF-5: Permeable Pavement

Permeable pavements contain small voids that allow water to pass through to a stone base. They come in a variety of forms; they may be a modular paving system (concrete pavers, grass-pave, or gravel-pave) or a poured-in-place solution (porous concrete or permeable asphalt). All permeable pavements with a stone reservoir base treat stormwater and remove sediments and metals to some degree. While conventional pavement result in increased rates and volumes of surface runoff, porous pavements when properly constructed and maintained, allow some of the stormwater to percolate through the pavement and enter the soil below. This facilitates groundwater recharge while providing the structural and functional features needed for the roadway, parking lot, or sidewalk. The paving surface, subgrade, and installation requirements of permeable pavements are more complex than those for conventional asphalt or concrete surfaces. For porous pavements to function properly over an expected life span of 15 to 20 years, they must be properly sited and carefully designed and installed, as well as periodically maintained. Failure to protect paved areas from construction-related sediment loads can result in their premature clogging and failure. Note that the 2011 TGM does not provide specific instructions on how to design and construct pavement.

Application

- Parking lots
- Driveways
- Sidewalks and walkways
- Outdoor athletic courts

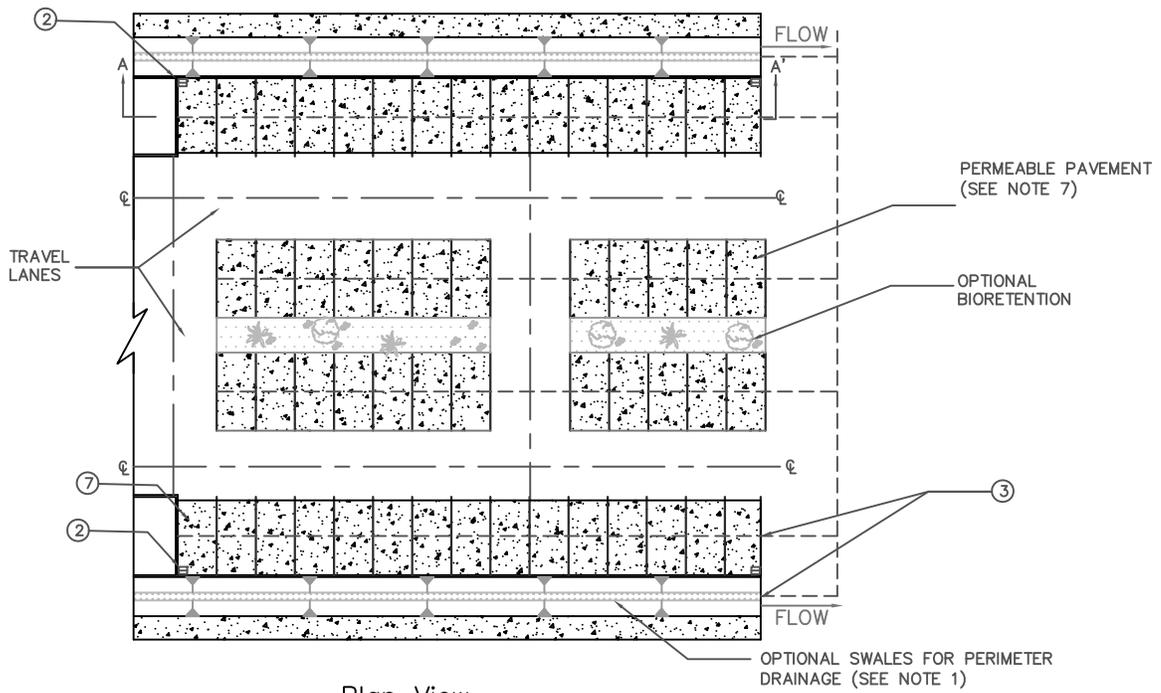

Preventative Maintenance

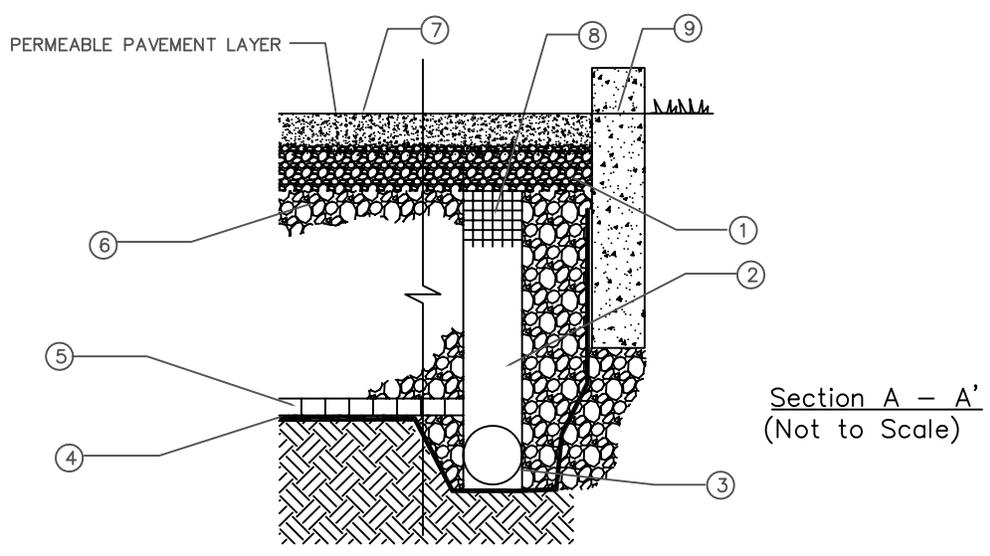

- Trash removal
- Post-rain inspections
- Vacuum sweeping
- Vegetation inspection and removal

Permeable pavement applications

Plan View
(Not to Scale)

Section A - A'
(Not to Scale)

NOTES:

- ① BEDDING COURSE SHALL BE 1½" TO 3" MIN THICKNESS (TYP NO. 8 AGGREGATE).
- ② OPTIONAL OVERFLOW PIPE(S) SHALL BE PROVIDED IF OVERFLOWS ARE NOT MANAGED VIA PERIMETER DRAINAGE TO SWALES, BIORETENTION OR STORM WATER CONVEYANCE SYSTEM INLETS.
- ③ CONNECT OUTFALL PIPES TO DOWNSTREAM STORMWATER CONVEYANCE SYSTEM. OUTFALL PIPES SHALL BE SLOPED TOWARDS COLLECTION SYSTEM.
- ④ SOIL SUBGRADE SHALL HAVE ZERO SLOPE.
- ⑤ INSTALL GEOTEXTILE OR CHOKING LAYER ON BOTTOM & SIDES OF OPEN-GRADED BASE FOR FULL AND PARTIAL INFILTRATION, OR AN IMPERMEABLE LINER FOR NO INFILTRATION.
- ⑥ OPEN-GRADED BASE. THICKNESS AND GRADATION VARIES WITH DESIGN. TYP. NO. 57 AGGREGATE OR 4" THICK NO. 57 OVER NO. 2 STONE SUBBASE. THICKNESS OF SUB-BASE VARIES WITH DESIGN.
- ⑦ PERMEABLE PAVEMENT INFILTRATIVE LAYER
- ⑧ OPTIONAL RIGID PLASTIC SCREEN FASTENED OVER OVERFLOW INLETS.
- ⑨ CURB/EDGE RESTRAINT WITH CUT-OUTS FOR OVERFLOW DRAINAGE TO PERIMETER BMPS, STORMWATER CONVEYANCE SYSTEM INLETS OR OPTIONAL OVERFLOW PIPES.
- ⑩ PARTIAL EXFILTRATION THROUGH THE SOIL. PERFORATED PIPES DRAIN EXCESS RUNOFF THAT CAN NOT BE ABSORBED BY SLOW-DRAINING SOIL.

Figure 6-6: Permeable Pavement

Limitations

The following describes limitations for the use of permeable pavement.

- Native soil infiltration rate - permeability of soils at the BMP location must be at least 0.5 inches per hour.
- Depth to groundwater, bedrock, or low permeability soil layer – 5 feet vertical separation is required between the bottom of the infiltration trench and the seasonal high groundwater level or mounded groundwater level, bedrock, or other infiltration barrier to ensure that the facility will completely drain between storms and that infiltrating water will receive adequate treatment through the soils before it reaches the groundwater.
- Slope stability - infiltration BMPs must be sited at least 50 feet away from slopes steeper than 15 percent or an alternative setback established by the geotechnical expert for the project.
- Setbacks - a minimum setback (100 feet or more) must be provided between infiltration BMPs and potable wells, non-potable wells, drain fields, and springs. Infiltration BMPs must be setback from building foundations at least eight feet or an alternative setback established by the geotechnical expert for the project.
- Groundwater contamination - the application of infiltration BMPs should include significant pretreatment in an area identified as an unconfined aquifer, to ensure groundwater is protected for pollutants of concern.
- Contaminated soils or groundwater plumes - infiltration BMPs are not allowed at locations with contaminated soils or groundwater where the pollutants could be mobilized or exacerbated by infiltration, unless a site-specific analysis determines the infiltration would be beneficial.
- High pollutant land uses - infiltration BMPs should not be placed in high-risk areas such as at or near a service/gas stations, truck stops, and heavy industrial sites due to the groundwater contamination risk unless a site-specific evaluation demonstrates that sufficient pretreatment is provided to address pollutants of concern, high risk areas are isolated from stormwater runoff, or infiltration areas that have little chance of spill migration.
- High sediment loading rates – infiltration BMPs may clog quickly if sediment loads are high (e.g., unstabilized site) or if flows are not adequately pretreated.
- Permeable pavement cannot receive untreated stormwater runoff from other surfaces. Pretreatment of run-on from other surfaces is necessary to prevent premature failure that results from clogging with fine sediment.

- Permeable pavement cannot be used to treat runoff from portions of the site that are not stabilized.

Design Criteria

Permeable pavement should be designed according to the requirements listed in Table 6-11 and outlined in the section below.

Table 6-11: Permeable Pavements Design Criteria

Design Parameter	Unit	Design Criteria
Stormwater Quality Design Volume (SQDV)	acre-feet	See Section 2 and Appendix E for calculating SQDV.
Pretreatment	-	Runoff from pervious areas should be minimized but, if provided, BIO-3: Vegetated Swale or BIO-4: Filter Strip should be provided for all runoff from offsite sources that are not directly adjacent to the permeable pavement.
Drawdown time of gravel drainage layer	hrs	12 - 72
Porous Pavement Infill		ASTM C-33 sand or equivalent
Minimum depth to bedrock	ft	2 (without underdrains)
Minimum depth to seasonal high water table	ft	2 (with underdrains); 10 (without underdrains)
Infiltration rate of subsoil	in/hr	1.0 (minimum without an underdrain)
Overflow device	-	Required

Geotechnical Considerations

An extensive geotechnical site investigation must be undertaken early in the site planning process to verify site suitability for the installation of infiltration facilities, due to the potential to contaminate groundwater, cause slope instability, impact surrounding structures, and have insufficient infiltration capacity. Soil infiltration rates and the water table depth should be evaluated to ensure that conditions are satisfactory for proper operation of an infiltration facility. See Appendix C for guidance on infiltration testing.

The project designer must demonstrate through infiltration testing, soil logs, and the written opinion of a licensed civil engineer that sufficiently permeable soils exist onsite to allow the construction of a properly functioning infiltration facility.

- 1) Infiltration facilities require a minimum native soil infiltration rate of 0.5 inches/hour. If infiltration rates exceed 2.4 inches/hour, then the runoff should be fully treated in an upstream BMP prior to infiltration to protect groundwater quality.

Pretreatment for removing coarse sediment present in runoff from the tributary area is required in all instances.

- 2) Groundwater separation must be at least 5 feet from the basin bottom to the measured season high groundwater elevation or estimated high groundwater mounding elevation. Groundwater levels measurements must be made during the time when the water level is expected to be at a maximum (i.e., toward the end of the wet season).
- 3) Sites with a slope greater than 25% (4:1) should be excluded. A geotechnical analysis and report addressing slope stability are required if located on slopes greater than 15%.

Soil Assessment and Site Geotechnical Investigation Reports

The soil assessment report should:

- State whether the site is suitable for the proposed permeable pavement;
- Recommend a design infiltration rate (see the Step 2 of sizing methodology section, “Determine the design percolation rate,” in the Infiltration Basin fact sheet above);
- Identify the seasonal high depth to groundwater table surface elevation;
- Provide a good understanding of how the stormwater runoff will move in the soil (horizontally or vertically) and if there are any geological conditions that could inhibit the movement of water; and
- If a geotechnical investigation and report are required, the report should:
 - Provide a written opinion by a professional civil engineer describing whether the infiltration trench will compromise slope stability; and
 - Identify potential impacts to nearby structural foundations.

Setbacks

- 1) Infiltration facilities shall be setback a minimum of 100 feet from proposed or existing potable wells, non-potable wells, septic drain fields, and springs.
- 2) Infiltration BMPs must be sited at least 50 feet away from slopes steeper than 15 percent or an alternative setback established by the geotechnical expert for the project.
- 3) Infiltration BMPs must be setback from building foundations at least eight feet or have an alternative setback established by the geotechnical expert for the project.

Pretreatment

- 1) Depending on how and where permeable pavements will be used, pretreatment of the runoff entering the permeable pavement may be necessary. This is particularly important when the permeable pavement will be accepting run-on from pervious areas or areas that are not completely stabilized. If this is the case, then the run-on should be treated prior to contacting the permeable pavement. Without adequate pretreatment, the life of the permeable pavement may be significantly decreased.
- 2) If sheet flow is conveyed to the permeable pavement over stabilized grassed areas, the site must be graded in such a way that minimizes erosive conditions.

Sizing Criteria

Permeable pavement must be designed to meet Ventura County codes and/or applicable local permitting authority codes. These sizing criteria are meant to provide guidance for runoff volume storage only.

Step 1: Calculate the Design Volume

Infiltration facilities shall be sized to capture and infiltrate the SQDV volume (see [Section 2](#) and Appendix E) with a 12 to 72 hour drawdown time (see Appendix D, Section D.2).

Step 2: Determine the Design Percolation Rate

The percolation rate will decline between maintenance cycles as the surface becomes occluded and particulates accumulate in the infiltration layer. Monitoring of actual facility performance has shown that the full-scale infiltration rate is far lower than the rate measured by small-scale testing. It is important that adequate conservatism is incorporated in the selection of design percolation rates. For infiltration trenches, the design percolation rate discussed here is the percolation rate of the underlying soils and not the percolation rate of the filter media bed (refer to the [“Geometry and Sizing”](#) section of INF-2 for the recommended composition of the filter media bed for infiltration trenches).

Considerations for Design Percolation Rate Corrections

Suitability assessment related considerations include (Table 6-12):

- Soil assessment methods – the site assessment extent (e.g., number of borings, test pits, etc.) and the measurement method used to estimate the short-term infiltration rate.
- Predominant soil texture/percent fines – soil texture and the percent of fines can greatly influence the potential for clogging.
- Site soil variability – site with spatially heterogeneous soils (vertically or horizontally) as determined from site investigations are more difficult to estimate

average properties resulting in a higher level of uncertainty associated with initial estimates.

- Depth to seasonal high groundwater/impervious layer – groundwater mounding may become an issue during excessively wet conditions where shallow aquifers or shallow clay lenses are present.

Table 6-12: Suitability Assessment Related Considerations for Infiltration Facility Safety Factors

Consideration	High Concern	Medium Concern	Low Concern
Assessment methods	Use of soil survey maps or simple texture analysis to estimate short-term infiltration rates	Direct measurement of ≥ 20 percent of infiltration area with localized infiltration measurement methods (e.g., infiltrometer)	Direct measurement of ≥ 50 percent of infiltration area with localized infiltration measurement methods or Use of extensive test pit infiltration measurement methods
Ventura Hydrology Manual soil number (measured infiltration rate)	3 ($f = 0.5 - 0.64$)	4 or 5 ($f = 0.65 - 0.91$)	6 or 7 ($f = 0.92$ or higher)
Site soil variability	Highly variable soils indicated from site assessment or limited soil borings collected during site assessment	Soil borings/test pits indicate moderately homogeneous soils	Multiple soil borings/test pits indicate relatively homogeneous soils
Depth to groundwater/impervious layer	<10 ft below facility bottom	10-30 ft below facility bottom	>30 below facility bottom

Localized infiltration testing refers to methods such as the double ring infiltrometer test (ASTM D3385-88) which measure infiltration rates over an area less than 10 sq-ft and do not attempt to account for soil heterogeneity. Extensive infiltration testing refers to methods that include excavating a significant portion of the proposed infiltration area, filling the excavation with water, and monitoring drawdown. In all cases, testing should be conducted in the area of the proposed BMP where, based on geotechnical data, soils appear least likely to support infiltration.

Design related considerations include (Table 6-13):

- Size of area tributary to facility – all things being equal, both physical and economic risk factors related to infiltration facilities increase with an increase in the tributary area served. Therefore facilities serving larger tributary areas should use more restrictive adjustment factors.
- Level of pretreatment/expected influent sediment loads – credit should be given for good pretreatment by allowing less restrictive factors to account for the reduced probability of clogging from high sediment loading. Also facilities designed to capture runoff from relatively clean surfaces such as rooftops are likely to see low sediment loads and therefore should be allowed to apply less restrictive safety factors.
- Redundancy – facilities that consist of multiple subsystems operating in parallel such that parts of the system remains functional when other parts fail and/or bypass should be rewarded for the built-in redundancy with less restrictive correction and safety factors. For example, if bypass flows would be at least partially treated in another BMP, the risk of discharging untreated runoff in the event of clogging the primary facility is reduced. A bioretention facility that overflows to a landscaped area is another example.

Compaction during construction – proper construction oversight is needed during construction to ensure that the bottom of the infiltration facility are not overly compacted. Facilities that do not commit to proper construction practices and oversight should have to use more restrictive correction and safety factors.

Table 6-13: Design Related Considerations for Infiltration Facility Safety Factors

Consideration	High Concern	Medium Concern	Low Concern
Tributary area size	Greater than 10 acres.	Greater than 2 acres but less than 10 acres.	2 acres or less.
Level of pre-treatment/ expected influent sediment loads	Pre-treatment from gross solids removal devices only, such as hydrodynamic separators, racks and screens AND tributary area includes landscaped areas, steep slopes, high traffic areas, or any other areas expected to produce high sediment, trash, or debris loads.	Good pre-treatment with BMPs that mitigate coarse sediments such as vegetated swales AND influent sediment loads from the tributary area are expected to be relatively low (e.g., low traffic, mild slopes, disconnected impervious areas, etc.).	Excellent pre-treatment with BMPs that mitigate fine sediments such as bioretention or media filtration OR sedimentation or facility only treats runoff from relatively clean surfaces, such as rooftops.
Redundancy of treatment	No redundancy in BMP treatment train.	Medium redundancy, other BMPs available in treatment train to maintain at least 50% of function of facility in event of failure.	High redundancy, multiple components capable of operating independently and in parallel, maintaining at least 90% of facility functionality in event of failure.
Compaction during construction	Construction of facility on a compacted site or elevated probability of unintended/ indirect compaction.	Medium probability of unintended/ indirect compaction.	Heavy equipment actively prohibited from infiltration areas during construction and low probability of unintended/ indirect compaction.

Adjust the measured short-term infiltration rate using a weighted average of several safety factors, using the worksheet shown in Table 6-14 below. The design percolation rate would be determined as follows:

- For each consideration shown in Table 6-12 and Table 6-13 above, determine whether the consideration is a high, medium, or low concern.
- For all high concerns assign a factor value of 3, for medium concerns assign a factor value of 2, and for low concerns assign a factor value of 1.
- Multiply each of the factors by the corresponding weight to get a product.

- Sum the products within each factor category to obtain a safety factor for each.
- Multiply the two safety factors together to get the final combined safety factor. If the combined safety factor is less than 2, then use 2 as the safety factor.
- Divide the measured short term infiltration rate by the combined safety factor to obtain the adjusted design percolation rate for use in sizing the infiltration facility.

Table 6-14: Infiltration Facility Safety Factor Determination Worksheet

Factor Category		Factor Description	Assigned Weight (w)	Factor Value (v)	Product (p) p = w x v
A	Suitability Assessment	Soil assessment methods	0.25		
		Predominant soil texture	0.25		
		Site soil variability	0.25		
		Depth to groundwater / impervious layer	0.25		
		Suitability Assessment Safety Factor, $S_A = \sum p$			
B	Design	Tributary area size	0.25		
		Level of pre-treatment/ expected sediment loads	0.25		
		Redundancy	0.25		
		Compaction during construction	0.25		
		Design Safety Factor, $S_B = \sum p$			
Combined Safety Factor = $S_A \times S_B$					

Note: The minimum combined adjustment factor shall not be less than 2.0 and the maximum combined adjustment factor shall not exceed 9.

Step 3: Determine the Gravel Drainage Layer Depth

Permeable pavement (including the base layers) should be designed to drain in less than 72 hours. The basis for this is that soils must be allowed to dry out periodically in order to restore hydraulic capacity to receive flows from subsequent storms, maintain infiltration rates, maintain adequate sub soil oxygen levels for healthy soil biota, and to provide proper soil conditions for biodegradation and retention of pollutants.

- 1) Calculate the maximum depth of runoff (d_{max}) that can be infiltrated within the drawdown time:

$$d_{max} = \frac{P_{design} \cdot t}{12} \tag{Equation 6-11}$$

Where:

d_{max} = maximum depth that can be infiltrated (ft)

P_{design} = design percolation rate of underlying soils (in/hr) (see Step 2, above)

t = drawdown time (12-72 hours) (hr)

2) Select the gravel drainage layer depth, (l), such that:

$$d_{max} \geq n \times l \quad \text{(Equation 6-12)}$$

Where:

d_{max} = maximum depth that can be infiltrated (ft) (see 1) above)

n = gravel drainage layer porosity(unitless)(generally about 40% or 0.40 for gravel)

l = gravel drainage layer depth (ft)

Step 4: Determine infiltrating surface area

3) Calculate infiltrating surface area for permeable pavement (A):

$$A = \frac{SQDV}{\frac{TP_{design}}{12} + nl} \quad \text{(Equation 6-13)}$$

Where:

P_{design} = design percolation rate of underlying soils (in/hr) (see Step 2, above)

n = gravel drainage layer porosity(unitless)[about 40% or 0.40 for gravel]

l = depth of gravel drainage layer (ft)

T = time to fill the gravel drainage layer with water (use 2 hours for most designs) (hr)

Geometry and Size

1) Permeable pavement shall be sized to capture and treat the stormwater quality design volume (SQDV).

2) Pavement design options include:

- a. Full or partial infiltration – A design for full infiltration uses an open graded base for maximum infiltration and storage of stormwater. The water infiltrates directly into the base and through the soil. Pipes may provide drainage in overflow conditions. Partial infiltration does not rely completely on infiltration through the soil to dispose all of the captured runoff. Some of the water may infiltrate into the soil and the remainder drained by pipes.
 - b. No infiltration – No infiltration is desirable when the soil has low permeability and low strength, or there are other site limitations. An underdrain should be provided if the depth to bedrock is less than 2 feet or the depth to the water table is less than 10 feet. By storing water for a time in the base and then slowly releasing it through pipes, the design behaves like an underground detention pond. In other cases, the soil of the sub-base may be compacted and stabilized to render improved support for vehicular loads. This practice reduces infiltration into the soil to nearly zero. The “no infiltration” option requires the use of geotextile and bedding between the pavement and the open graded base.
- 3) If permeable pavement is located on a site with a slope greater than 2%, the permeable pavement area should be terraced to prevent lateral flow through the subsurface. Permeable pavement cannot be located on a site with a slope greater than 5%.
- 4) Porous pavement systems generally consist of at least four different layers of material:
- a. The top or wearing layer consists of either asphalt or concrete with a greater than normal percentage of voids (typically 12 to 20 percent in the case of asphalt). The wearing layer may also be comprised of lattice-type pavers (either hollow concrete blocks or paving stones made from solid conventional concrete or stone), which are set in a bedding material (sand, pea-sized gravel or turf grass).
 - b. Below the wearing layer, a stone reservoir layer or a thick layer of aggregate (e.g., 2 inch stone) provides the bulk of the water storage capacity for a porous pavement system. In the pavement design, it is important to ensure that this reservoir layer retains its load bearing capacity under saturated conditions, because it may take several days for complete drainage to occur.
 - c. Typically, porous pavement designs include two (or more) transition layers that can be constructed from 1 to 2 inch diameter stone. One transition layer separates the top wearing layer from the underlying stone reservoir layer. Another transition layer is used to separate the stone reservoir from the undisturbed subgrade soil. Some designs also add a geotextile layer to this bottom layer or some combination of stones and geotextiles.

- d. Porous asphalt pavement, for example, consists of open grade asphalt mixture ranging in depth from 2 to 4 inches with 16 percent voids. The thickness selected depends on bearing strength and pavement design requirements. This layer sits on a 2 to 4 inch transition layer located over a stone reservoir. The bottom layer completes the transition to the underlying undisturbed soil using a combination transition/filter fabric layer.
 - e. The depth of each layer should be determined by a licensed civil engineer based on analyses of the hydrology, hydraulics, and structural requirements of the site.
- 5) Modular paving stones are also used to create porous pavements. These pavements can be constructed in situ by pouring concrete into special frames or by using preformed blocks. The top layer of these porous pavements consists of conventional concrete, with the intervening void areas filled with either turf or sand. A transition or bedding layer is used to make the transition to the reservoir layer. These lattice-type pavers or hollow concrete blocks are often used in conjunction with turf grasses and are used in low-traffic parking lots, lanes, or driveways. Porous pavements using paving stones have similar construction, but can be designed to have a much higher load bearing capacity, and therefore have more widespread applicability. Construction guidelines and design specifications are available from the manufacturers of these products.
- 6) Permeable pavement (including the base layers) should be designed to drain in less than 72 hours. The basis for this is that soils must be allowed to dry out periodically in order to restore hydraulic capacity to receive flows from subsequent storms, maintain infiltration rates, maintain adequate subsoil oxygen levels for healthy soil biota, and to provide proper soil conditions for biodegradation and retention of pollutants.
- 7) The percolation rate will decline as the surface becomes occluded and particulates accumulate in the infiltration layer. It is important that adequate conservatism is incorporated in the selection of design percolation rates.

Overflow

An overflow mechanism is required. Two options are provided:

Option 1: Perimeter control

Flows in excess of the design capacity of the permeable pavement system will require an overflow system connected to a downstream conveyance or other stormwater runoff BMP. In addition, if the pavement becomes clogged and infiltration decreases to the point that there is ponding, runoff will migrate off of the pavement via overland flow instead of infiltrating into the subsurface gravel layer. There are several options for handling overflow using perimeter controls such as:

- 1) Perimeter vegetated swale.
- 2) Perimeter bioretention.
- 3) Storm drain inlets.
- 4) Rock filled trench that funnels flow around pavement and into the subsurface gravel layer.

Option 2: Overflow pipe(s)

- 1) A vertical pipe should be connected to the underdrain.
- 2) The diameter, location, and quantity may vary with design and should be determined by a licensed civil engineer.
- 3) The pipe should be located away from vehicular traffic.
- 4) The piping system may incorporate an observational and/or cleanout well.
- 5) The top of the overflow pipe should be covered with a screen fastened over the overflow inlet.

Construction Considerations

- 1) Permeable pavement should be laid close to level and the bottom of the base layers must be level to ensure uniform infiltration.
- 2) Permeable pavement surfaces should not be used to store site materials, unless the surface is well protected from accidental spillage or other contamination.
- 3) To prevent/minimize soil compaction in the area of the permeable pavement installation, use light equipment with tracks or oversized tires.
- 4) Divert stormwater from the area as needed (before and during installation).
- 5) The pavement should be the last installation done at a development site. Landscaping should be completed and adjacent areas stabilized, before pavement installation to minimize the risk of clogging.
- 6) Vehicular traffic should be prohibited for at least 2 days after installation.

Operations and Maintenance

Permeable pavement mainly requires vacuuming and management of adjacent areas to limit sediment contamination and prevent clogging by fine sediment particles. Therefore, little special training is needed for maintenance crews. The following maintenance concerns and maintenance activities shall be considered and provided:

- 1) Trash tends to accumulate in paved areas, particularly in parking lots and along roadways. The need for litter removal should be determined through periodic inspection.
- 2) Regularly (e.g., monthly for a few months after initial installation, then quarterly) inspect pavement for pools of standing water after rain events, this could indicate surface clogging.
- 3) Actively (3 to 4 times per year, or more frequently depending onsite conditions) vacuum sweep the pavement to reduce the risk of clogging by frequently removing fine sediments before they can clog the pavement and subsurface layers. This also helps to prolong the functional period of the pavement.
- 4) Inspect for vegetation growth on pavement and remove when present.
- 5) Inspect for missing sand/gravel in spaces between pavers and replace as needed.
- 6) Activities that lead to ruts or depressions on the surface should be prevented or the integrity of the pavement should be restored by patching or repaving. Examples are vehicle tracks and utility maintenance.
- 7) Spot clogging of porous concrete may be remedied by drilling 0.5 inch holes every few feet in the concrete.
- 8) Interlocking pavers that are damaged should be replaced.
- 9) Maintain landscaped areas and reseed bare areas.

INF-6: Proprietary Infiltration

A number of vendors offer proprietary infiltration products that allow for similar or enhanced rates of infiltration and subsurface storage while offering durable prefabricated structures. There are many varieties of proprietary infiltration BMPs.

Application

- Mixed-use and commercial
- Roads and parking lots
- Parks and open spaces
- Single and multi-family residential

Routine Maintenance

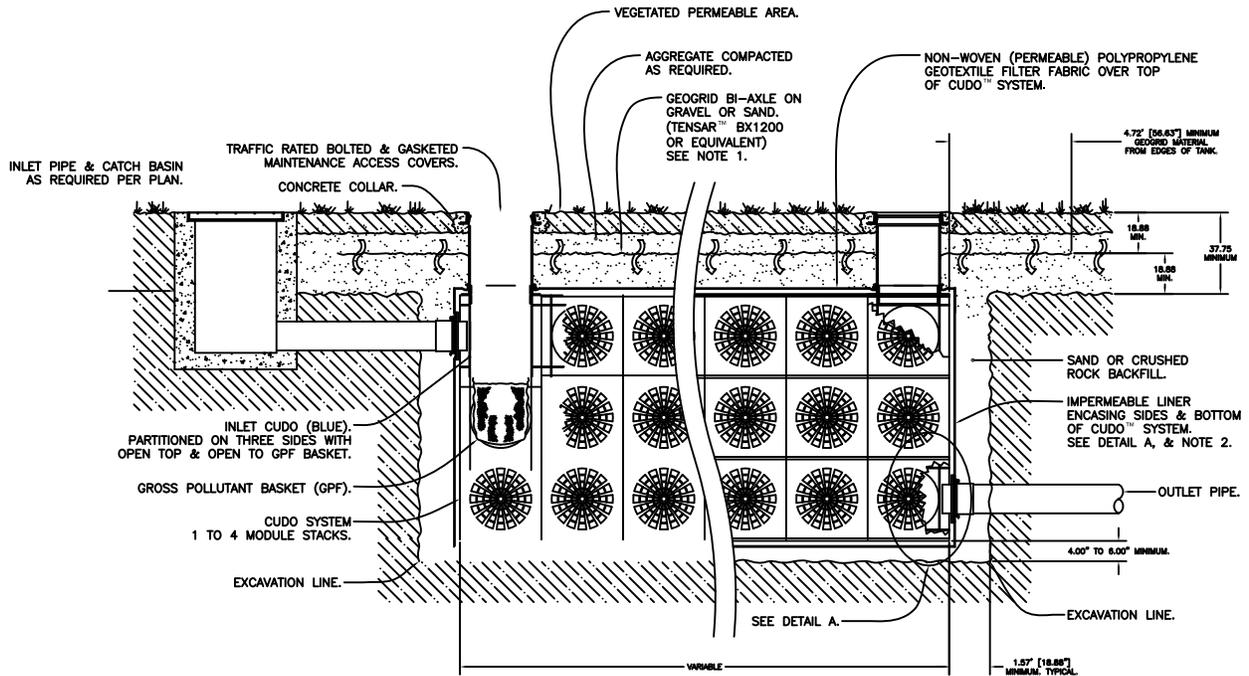

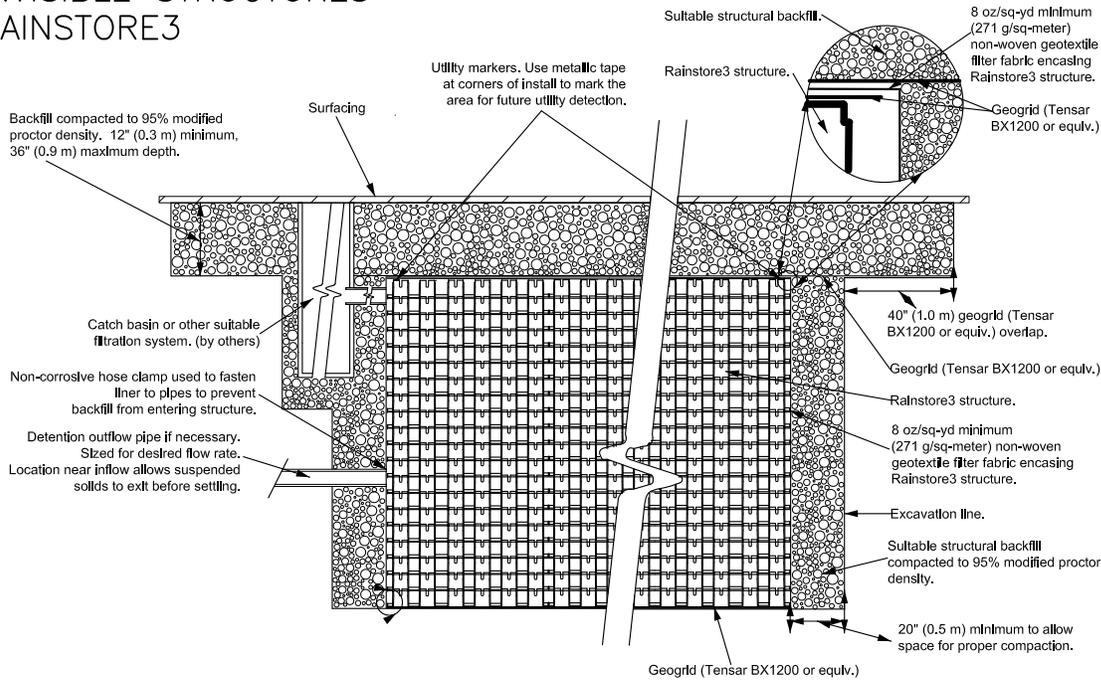

- Removal trash, debris, and sediment at inlet and outlets
- Wet weather inspection to ensure drain time
- Inspect for mosquito breeding

Figure 6-7: Proprietary Infiltration BMPs

Limitations

The following limitations shall be considered before choosing to use an infiltration BMP:

- Native soil infiltration rate - soil permeability of the infiltration basin location must be at least 0.5 inches per hour.
- Depth to groundwater, bedrock, or low permeability soil layer – 5 feet vertical separation is required between the bottom of the infiltration basin and the seasonal high groundwater level or mounded groundwater level, bedrock, or other barrier to infiltration to ensure that the facility will completely drain between storms and that infiltrating water will receive adequate treatment through the soils before it reaches the groundwater.
- Slope stability - infiltration BMPs must be sited at least 50 feet away from slopes steeper than 15 percent or an alternative setback established by the geotechnical expert for the project.
- Setbacks - a minimum setback (100 feet or more) must be provided between infiltration BMPs and potable wells, non-potable wells, drain fields and springs. Infiltration BMPs must be setback from building foundations at least eight feet or have an alternative setback established by the geotechnical expert for the project.
- Groundwater contamination - the application of infiltration BMPs should include significant pretreatment in an area identified as an unconfined aquifer, to ensure groundwater is protected for pollutants of concern.
- Contaminated soils or groundwater plumes - infiltration BMPs are not allowed at locations with contaminated soils or groundwater where the pollutants could be mobilized or exacerbated by infiltration, unless a site-specific analysis determines the infiltration would be beneficial.
- High pollutant land uses - infiltration BMPs should not be placed in high-risk areas such as at or near service/gas stations, truck stops, and heavy industrial sites due to the groundwater contamination risk unless a site-specific evaluation demonstrates that sufficient pretreatment is provided to address pollutants of concern, high risks areas are isolated from stormwater runoff, or infiltration areas have little chance of spill migration
- High sediment loading rates – infiltration BMPs may clog quickly if sediment loads are high (e.g., unstabilized site) or if flows are not adequately pretreated.

Geotechnical Considerations

An extensive geotechnical site investigation must be undertaken early in the site planning process to verify site suitability for the installation of infiltration facilities, due to the potential to contaminate groundwater, cause slope instability, impact surrounding structures, and have insufficient infiltration capacity. Soil infiltration rates and the water table depth should be evaluated to ensure that conditions are satisfactory for proper operation of an infiltration facility. See Appendix C for guidance on infiltration testing.

The project designer must demonstrate through infiltration testing, soil logs, and the written opinion of a licensed civil engineer that sufficiently permeable soils exist onsite to allow the construction of a properly functioning infiltration facility.

- 1) Infiltration facilities require a minimum soil infiltration rate of 0.5 inches/hour. If infiltration rates exceed 2.4 inches/hour such that pollutant removal may not be adequate to protect groundwater quality, then the runoff should be fully treated in an upstream BMP prior to infiltration to protect groundwater quality. Pretreatment for coarse sediment removal is required in all instances.
- 2) Groundwater separation must be at least 5 feet from the basin bottom to the measured season high groundwater elevation or estimated high groundwater mounding elevation. Measurements of groundwater levels must be made during the time when water level is expected to be at a maximum (i.e., toward the end of the wet season).
- 3) Sites with a slope greater than 25% (4:1) should be excluded. A geotechnical analysis and report addressing slope stability are required if located on slopes greater than 15%.

Soil Assessment and Site Geotechnical Investigation Reports

The soil assessment report should:

- State whether the site is suitable for the proposed proprietary infiltration BMP.;
- Recommend a design infiltration rate (see the Step 2 of sizing methodology section, “Determine the design percolation rate,” in the Infiltration Basin fact sheet above);
- Identify the seasonal high depth to groundwater table surface elevation;
- Provide a good understanding of how the stormwater runoff will move in the soil (horizontally or vertically) and if there are any geological conditions that could inhibit the movement of water; and
- If a geotechnical investigation and report are required, the report should:
 - Provide a written opinion by a professional civil engineer describing whether the infiltration trench will compromise slope stability; and
 - Identify potential impacts to nearby structural foundations.

Setbacks

- 1) Infiltration facilities shall be setback a minimum of 100 feet from proposed or existing potable wells, non-potable wells, septic drain fields, and springs.
- 2) Infiltration BMPs must be sited at least 50 feet away from slopes steeper than 15 percent or an alternative setback established by the geotechnical expert for the project.

- 3) Infiltration BMPs must be setback from building foundations at least eight feet or have an alternative setback established by the geotechnical expert for the project.

Pretreatment

Pretreatment is required for proprietary infiltration BMPs in order to reduce the sediment load entering the facility and maintain the infiltration rate of the facility. Pretreatment refers to design features that provide settling of sediment particles before runoff reaches a management practice. This eases the long-term maintenance burden and likelihood of failure. Pretreatment is important for most stormwater treatment BMPs, but it is particularly important for infiltration BMPs. To ensure that pretreatment mechanisms are effective, designers should incorporate sediment reduction practices. Sediment reduction BMPs may include vegetated swales, vegetated filter strips, sedimentation basins, sedimentation manholes and hydrodynamic separation devices. The use of at least two pretreatment devices is highly recommended for infiltration BMPs.

Sizing

- 1) Proprietary infiltration BMPs shall be sized to capture and treat the stormwater quality design volume (SQDV). See Section 2 and Appendix E for calculating for further detail.
- 2) The percolation rate will decline as the surface becomes occluded and particulates accumulate in the infiltrative layer. It is important that adequate conservatism is incorporated in the selection of design percolation rates.
- 3) For the sizing guidelines, refer to the manufacturer's website.

Operations and Maintenance

See vendor's website for maintenance requirements.

INF-7: Bioinfiltration

Bioinfiltration facilities are designed for partial infiltration of runoff and partial biotreatment. These facilities are similar to bioretention devices with underdrains, but the underdrain is raised above the gravel sump to facilitate infiltration. These facilities can be used in areas where there are no hazards associated with infiltration, but infiltration of the full DCV may not be feasible due to low infiltration rates (Soil Type 3) or high depths of fill. These facilities may not result in retention of the DCV but they can be used to meet the MEP standards.

Bioretention in Parkway and parking lots

Photo Credits: Geosyntec Consultants

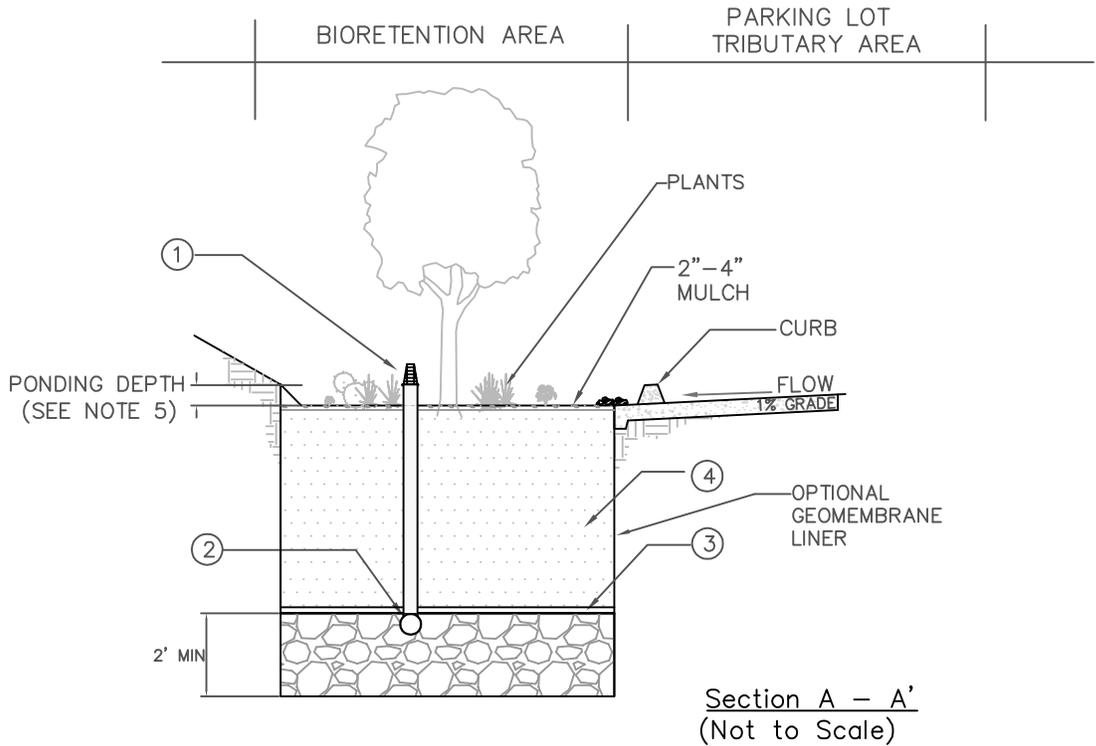

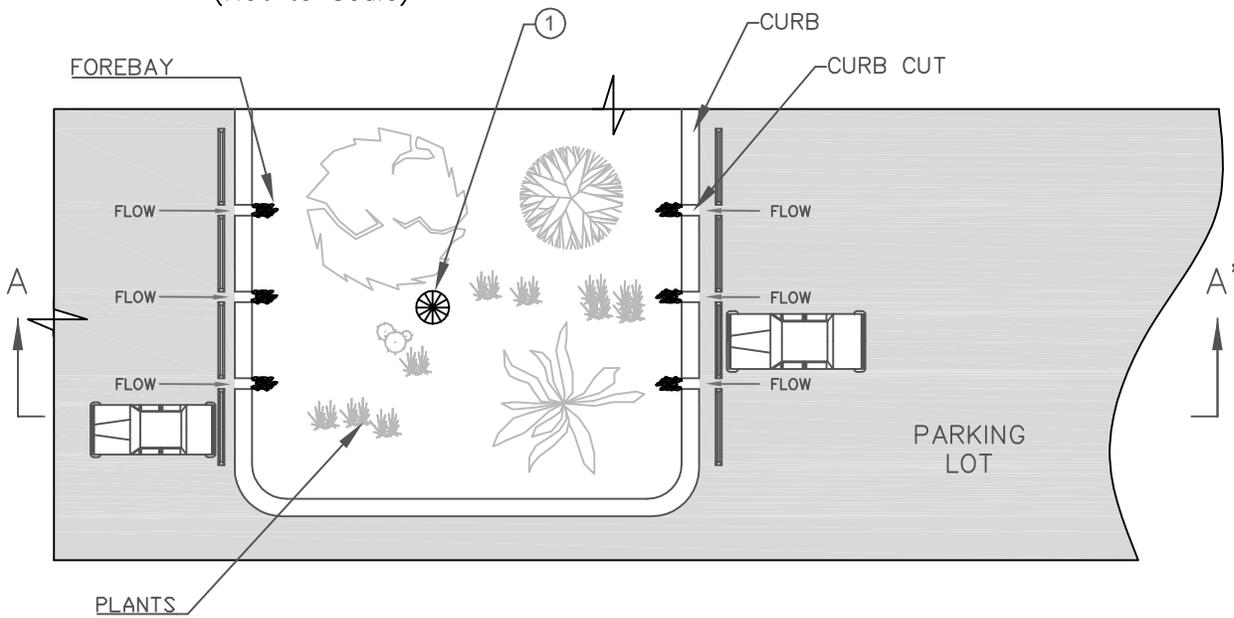

Application

- Commercial, residential, mixed use, institutional, and recreational uses
- Parking lot islands, traffic circles
- Road parkways & medians

Preventative Maintenance

- Repair small eroded areas
- Remove trash and debris and rake surface soils
- Remove accumulated fine sediments, dead leaves and trash
- Remove weeds and prune back excess plant growth
- Remove sediment and debris accumulation near inlet and outlet structures
- Periodically observe function under wet weather conditions

- ⑥ 2' MIN GRAVEL LAYER DEPTH.

Figure 6-8: Bioinfiltration

Limitations

The following limitations should be considered before choosing to use bioinfiltration:

- 1) Native soil infiltration rate - soil permeability at the bioinfiltration location must be no less than 0.3 inches per hour.
- 2) Depth to groundwater, bedrock, or low permeability soil layer – 5 feet vertical separation is required between the bottom of the infiltration trench and the seasonal high groundwater level or mounded groundwater level, bedrock, or other barrier to infiltration to ensure that the facility will completely drain between storms and that infiltrating water will receive adequate treatment through the soils before it reaches the groundwater.
- 3) Slope stability - infiltration BMPs must be sited at least 50 feet away from slopes steeper than 15 percent or an alternative setback established by the geotechnical expert for the project.
- 4) Setbacks - a minimum setback (100 feet or more) must be provided between infiltration BMPs and potable wells, non-potable wells, drain fields, and springs. Infiltration BMPs must be setback from building foundations at least eight feet or have an alternative setback established by the geotechnical expert for the project.
- 5) Groundwater contamination - the application of infiltration BMPs should include significant pretreatment in an area identified as an unconfined aquifer to ensure groundwater is protected for pollutants of concern.
- 6) Contaminated soils or groundwater plumes - infiltration BMPs are not allowed at locations with contaminated soils or groundwater where the pollutants could be mobilized or exacerbated by infiltration, unless a site-specific analysis determines that infiltration would be beneficial.
- 7) High pollutant land uses - infiltration BMPs should not be placed in high-risk areas such as at or near service/gas stations, truck stops, and heavy industrial sites due to the groundwater contamination risk unless a site-specific evaluation demonstrates that sufficient pretreatment is provided to address pollutants of concern, high risk areas are isolated from stormwater runoff, or infiltration areas have little chance of spill migration.
- 8) High sediment loading rates – infiltration BMPs may clog quickly if sediment loads are high (e.g., unstabilized site) or if flows are not adequately pretreated.
- 9) Vertical relief and proximity to storm drain - site must have adequate relief between the land surface and storm drain to permit vertical percolation through the soil media and collection.

Design Criteria

Bioinfiltration should be designed according to the requirements listed in Table 6-16 and outlined in the section below.

Table 6-16: Bioretention Design Criteria

Design Parameter	Unit	Design Criteria
Stormwater quality design volume (SQDV)	acre-feet	See Section 2 and Appendix E for calculating SQDV.
Forebay	-	Forebay should be provided for all tributary surfaces that contain landscaped areas. Forebays should be designed to prevent standing water during dry weather and should be planted with a plant palette that is tolerant of wet conditions.
Maximum drawdown time of water ponded on surface	hours	48
Maximum drawdown time of surface ponding plus subsurface pores	hours	96 (72 preferred)
Maximum ponding depth	inches	18
Minimum thickness of amended soil	feet	2 (3 preferred)
Minimum thickness of stabilized mulch	inches	2 to 4
Planting mix composition	-	60 to 80% fine sand, 20 to 40% compost
Underdrain sizing	-	Underdrain should be installed below the choking stone; 6 inch minimum diameter; 0.5% minimum slope; slotted, polyvinyl chloride (PVC) pipe (PVC SDR 35 or approved equivalent); spacing shall be determined to provide capacity for maximum rate filtered through amended media
Minimum thickness of gravel layer	feet	2
Overflow device	-	Required

Sizing Criteria

Bioinfiltration facilities can be sized using one of two methods: a simple sizing method or a routing modeling method. With either method the SQDV volume must be completely infiltrated within 96 hours (including subsurface pore space), and surface ponding must be infiltrated within 48 hours. The simple sizing procedure is provided below. For the routing modeling method, refer to [TCM-4 Sand Filters](#).

Step 1: Calculate the Design Volume

Bioinfiltration facilities shall be sized to capture and partially infiltrate and partially biotreat the SQDV volume (see Section 2.3 and Appendix E).

Step 2: Determine the Design Percolation Rate

The percolation rate through the BMP and to the subsurface will decline between maintenance cycles as the surface becomes occluded and particulates accumulate in the infiltration layer. Monitoring of actual facility performance has shown that the full-scale infiltration rate is far lower than the rate measured by small-scale testing. It is important that adequate conservatism is incorporated in the selection of design percolation rates. For bioinfiltration facilities, the design percolation rate discussed here is the adjusted percolation rate of the underlying soils and not the percolation rate of the filter media bed. The measured short-term infiltration rate should be adjusted using a factor of safety of 2.0.

Step 3: Calculate the surface area

Determine the size of the required infiltrating surface by assuming the SQDV will fill the available ponding depth plus the void spaces in the media, based on the computed porosity of the filter media and optional aggregate layer.

- 1) Determine the maximum depth of surface ponding that can be infiltrated within the required surface drain time (48 hr), (d_{max}), as follows:

$$d_{max} = \frac{P_{design} \times t_{ponding}}{12 \frac{in}{ft}} \quad \text{(Equation 6-14)}$$

Where:

- | | | |
|---------------|---|---|
| $t_{ponding}$ | = | required drain time of surface ponding (48 hrs) |
| P_{design} | = | design percolation rate of underlying soils (in/hr) (see Step 2, above) |

d_{max} = the maximum depth of surface ponding water that can be infiltrated within the required drain time (ft), calculated using Equation 6-14

2) Choose surface ponding depth (d_p) such that:

$$d_p \leq d_{max} \quad \text{(Equation 6-15)}$$

Where:

d_p = selected surface ponding depth (ft)

d_{max} = the maximum depth of water that can be infiltrated within the required drain time (ft)

Choose thickness(es) of amended media and aggregate layer(s) and calculate total effective storage depth of the bioinfiltration area ($d_{effective}$), as follows:

$$d_{effective} \leq (d_p + n_{media}^* l_{media} + n_{gravel} l_{gravel}) \quad \text{(Equation 6-16)}$$

Where:

$d_{effective}$ = total equivalent depth of water stored in bioinfiltration area (ft), including surface ponding and volume available in pore spaces of media and gravel layers

d_p = surface ponding depth (ft), chosen using Equation 6=15

n_{media}^* = available porosity of amended soil media (ft/ft), approximately 0.25 ft/ft accounting for antecedent moisture conditions. This represents the volume of available pore space as a fraction of the total soil volume; sometimes has units of (ft³/ft³) or described as a percentage.

l_{media} = thickness of amended soil media layer (ft), minimum 2 ft

n_{gravel} = porosity of gravel layer (ft/ft), approximately 0.40 ft/ft

l_{gravel} = thickness of gravel layer (ft), minimum 2 ft

3) Check that entire effective depth (surface plus subsurface storage), $d_{effective}$, infiltrates in no greater than 96 hours as follows:

$$t_{total} = \frac{d_{effective}}{P_{design}} \times 12 \frac{in}{ft} \leq 96 \text{ hr} \quad (\text{Equation 6-17})$$

Where:

$d_{effective}$ = total equivalent depth of water stored in bioinfiltration area (ft), calculated using Equation 6-16

P_{design} = design percolation rate of underlying soils (in/hr) (see Step 2, above)

If $t_{total} > 96$ hrs, then reduce surface ponding depth and/or amended media thickness and/or gravel thickness and return to 1).

If $t_{total} \leq 96$ hrs, then proceed to 5).

- 4) Calculate required infiltrating surface area, (A_{req}):

$$A_{req} = \frac{SQDV}{d_{effective}} \quad (\text{Equation 6-18})$$

Where:

A_{req} = required infiltrating area (ft²). Should be calculated at the contour corresponding to the mid ponding depth (i.e., $0.5 \times d_p$ from the bottom of the facility).

$SQDV$ = stormwater quality design volume (ft³)

$d_{effective}$ = total equivalent depth of water stored in bioinfiltration area (ft), calculated using Equation 6-16

- 5) Calculate total footprint required by including a buffer for side slopes and freeboard; A_{req} is calculated at the contour corresponding to the mid ponding depth (i.e., $0.5 \times d_p$ from the bottom of the facility).

Geometry

- 1) Minimum planting soil depth should be 2 feet, although 3 feet is preferred.

The intention is that the minimum planting soil depth should provide a beneficial root zone for the chosen plant palette and adequate water storage for the stormwater quality design volume. A deeper soil depth will provide a smaller surface area footprint.

- 2) Minimum gravel layer depth is 2 feet.

The intention is that the gravel sump provides partial retention of captured water.

- 3) Bioinfiltration should be designed to drain below the planting soil in less than 48 hours and completely drain from the gravel layer in 96 hours (both starting from the end of inflow).

The intention is that soils must be allowed to dry out periodically in order to restore hydraulic capacity to receive flows from subsequent storms, maintain infiltration rates, maintain adequate soil oxygen levels for healthy soil biota and vegetation, and to provide proper soil conditions for biodegradation and retention of pollutants.

Flow Entrance and Energy Dissipation

The following types of flow entrance can be used for bioinfiltration cells:

- 1) Dispersed, low velocity flow across a landscape area. Dispersed flow may not be possible given space limitations or if the facility is controlling roadway or parking lot flows where curbs are mandatory.
- 2) Dispersed flow across pavement or gravel and past wheel stops for parking areas.
- 3) Curb cuts for roadside or parking lot areas: curb cuts should include rock or other erosion protection material in the channel entrance to dissipate energy. Flow entrance should drop 2 to 3 inches from curb line and it should provide a settling area and periodic sediment removal of coarse material before flow dissipates to the remainder of the cell.
- 4) Pipe flow entrance: Piped entrances, such as roof downspouts, should include rock, splash blocks, or other appropriate measures at the entrance to dissipate energy and disperse flows.

Woody plants (trees, shrubs, etc.) can restrict or concentrate flows and can be damaged by erosion around the root ball and should not be placed directly in the entrance flow path.

Underdrains

Underdrains should meet the following criteria:

- 1) 6-inch minimum diameter.
- 2) Underdrains should be made of slotted, polyvinyl chloride (PVC) pipe (PVC SDR 35 or approved equivalent). *The intention is that compared to round-hole perforated pipe, slotted underdrains provide greater intake capacity, clog resistant drainage, and reduced entrance velocity into the pipe, thereby reducing the chances of solids migration.*

- 3) Slotted pipe should have 2 to 4 rows of slots cut perpendicular to the axis of the pipe or at right angles to the pitch of corrugations. Slots should be 0.04 to 0.1 inches and should have a length of 1 to 1.25 inches. Slots should be longitudinally spaced such that the pipe has a minimum of one square inch of slot per lineal foot of pipe and should be placed with slots facing the bottom of the pipe.
- 4) Underdrains should be sloped at a minimum of 0.5%.
- 5) Rigid non-perforated observation pipes with a diameter equal to the underdrain diameter should be connected to the underdrain every 100 feet to provide a clean-out port as well as an observation well to monitor dewatering rates. The wells/cleanouts should be connected to the perforated underdrain with the appropriate manufactured connections. The wells/cleanouts should extend 6 inches above the top elevation of the bioinfiltration facility mulch, and should be capped with a lockable screw cap. The ends of the underdrain pipes not terminating in an observation well/cleanout should also be capped.

Gravel Layer

- 1) The following aggregate should be used for the gravel layer below the underdrain pipe. Place the underdrain below the choking stone, within the top 6 inches of the gravel layer.

Sieve size	Percent Passing
¾ inch	100
¼ inch	30-60
US No. 8	20-50
US No. 50	3-12
US No. 200	0-1

- 2) At the option of the designer/geotechnical engineer, a geotextile fabric may be placed between the planting media and the gravel layer. If a geotextile fabric is used, it should meet a minimum permittivity rate of 75 gal/min/ft², should not impede the infiltration rate of the soil medium, and should meet the following minimum materials requirements.

Geotextile Property	Value	Test Method
Trapezoidal Tear (lbs)	40 (min)	ASTM D4533
Permeability (cm/sec)	0.2 (min)	ASTM D4491
AOS (sieve size)	#60 - #70 (min)	ASTM D4751
Ultraviolet resistance	70% or greater	ASTM D4355

Preferably, aggregate (choking stone) should be used in place of filter fabric to reduce the potential for clogging. This aggregate layer should consist of 2 to 4 inches

of washed sand underlain with 2 inches of choking stone (Typically #8 or #89 washed).

- 3) Bioinfiltration facilities have the added benefit of enhanced nitrogen removal due to the elevated underdrain. This allows for a fluctuating anaerobic/aerobic zone below the drain pipe. *The intention is that denitrification within the anaerobic/anoxic zone is facilitated by microbes using forms of nitrogen (NO₂ and NO₃) instead of oxygen for respiration.*
- 4) The underdrain should drain freely to an acceptable discharge point. The underdrain can be connected to a downstream open conveyance (vegetated swale), to another bioinfiltration cell as part of a connected treatment system, to a storm drain, daylight to a vegetated dispersion area using an effective flow dispersion device, or to a storage facility for harvesting.

Overflow

An overflow device is required at the 18-inch ponding depth. The following, or equivalent should be provided:

- 1) A vertical PVC pipe (SDR 35) to act as an overflow riser.
- 2) The overflow riser(s) should be 6 inches or greater in diameter, so it can be cleaned without damage to the pipe.

The inlet to the riser should be at the ponding depth (18 inches for fenced bioinfiltration areas and 6 inches for areas that are not fenced), and be capped with a spider cap to exclude floating mulch and debris. Spider caps should be screwed in or glued, i.e., not removable.

Hydraulic Restriction Layers

Infiltration pathways may need to be restricted due to the close proximity of roads, foundations, or other infrastructure. A geomembrane liner, or other equivalent water proofing, may be placed along the vertical walls to reduce lateral flows. This liner should have a minimum thickness of 30 mils.

Planting/Storage Media

- 1) The planting media placed in the cell should achieve a long-term, in-place infiltration rate of at least 1 inch per hour. Higher infiltration rates are permissible. If the design long-term, in-place infiltration rate of the soil exceeds 12 inches per hour, documentation should be provided to demonstrate that the media will adequately address pollutants of concern at a higher flowrate. Bioinfiltration soil shall also support vigorous plant growth.
- 2) Planting media should consist of 60 to 80% fine sand and 20 to 40% compost.

- 3) Sand should be free of wood, waste, coating such as clay, stone dust, carbonate, etc., or any other deleterious material. All aggregate passing the No. 200 sieve size should be non-plastic. Sand for bioinfiltration should be analyzed by an accredited lab using #200, #100, #40, #30, #16, #8, #4, and 3/8 sieves (ASTM D 422 or as approved by the local permitting authority) and meet the following gradation (Note: all sands complying with ASTM C33 for fine aggregate comply with the gradation requirements below):

Sieve Size (ASTM D422)	% Passing (by weight)	
	Minimum	Maximum
3/8 inch	100	100
#4	90	100
#8	70	100
#16	40	95
#30	15	70
#40	5	55
#100	0	15
#200	0	5

Note: the gradation of the sand component of the media is believed to be a major factor in the hydraulic conductivity of the media mix. If the desired hydraulic conductivity of the media cannot be achieved within the specified proportions of sand and compost (#2), then it may be necessary to utilize sand at the coarser end of the range specified in above (“minimum” column).

- 4) Compost should be a well decomposed, stable, weed free organic matter source derived from waste materials including yard debris, wood wastes, or other organic materials not including manure or biosolids meeting standards developed by the US Composting Council (USCC). The product shall be certified through the USCC Seal of Testing Assurance (STA) Program (a compost testing and information disclosure program). Compost quality should be verified via a lab analysis to be:
- Feedstock materials shall be specified and include one or more of the following: landscape/yard trimmings, grass clippings, food scraps, and agricultural crop residues.
 - Organic matter: 35-75% dry weight basis.
 - Carbon and Nitrogen Ratio: $15:1 < C:N < 25:1$
 - Maturity/Stability: shall have dark brown color and a soil-like odor. Compost exhibiting a sour or putrid smell, containing recognizable grass or leaves, or is hot (120 F) upon delivery or rewetting is not acceptable.

- Toxicity: any one of the following measures is sufficient to indicate non-toxicity:
 - $\text{NH}_4:\text{NH}_3 < 3$
 - Ammonium < 500 ppm, dry weight basis
 - Seed Germination $> 80\%$ of control
 - Plant trials $> 80\%$ of control
 - e. Solvita® > 5 index value
- Nutrient content:
 - Total Nitrogen content 0.9% or above preferred
 - Total Boron should be < 80 ppm, soluble boron < 2.5 ppm
- Salinity: < 6.0 mmhos/cm
- pH between 6.5 and 8 (may vary with plant palette)

Compost for bioinfiltration should be analyzed by an accredited lab using #200, ¼ inch, ½ inch, and 1 inch sieves (ASTM D 422 or as approved by the local permitting authority) and meet the following gradation:

Sieve Size (ASTM D422)	% Passing (by weight)	
	Minimum	Maximum
1 inch	99	100
½ inch	90	100
¼ inch	40	90
#200	2	10

Tests should be sufficiently recent to represent the actual material that is anticipated to be delivered to the site. If processes or sources used by the supplier have changed significantly since the most recent testing, new tests should be requested.

Note: the gradation of compost used in bioinfiltration media is believed to play an important role in the saturated hydraulic conductivity of the media. To achieve a higher saturated hydraulic conductivity, it may be necessary to utilize compost at the coarser end of this range (“minimum” column). The percent passing the #200 sieve (fines) is believed to be the most important factor in hydraulic conductivity.

In addition, a coarser compost mix provides more heterogeneity of the bioinfiltration media, which is believed to be advantageous for more rapid development of soil structure needed to support health biological processes. This may be an advantage for plant establishment with lower nutrient and water input.

- 5) The bioinfiltration area should be covered with 2 to 4 inches (average 3 inches) of mulch at the start and an additional placement of 1 to 2 inches of mulch should be added annually. *The intention is that to help sustain the nutrient levels, suppress weeds, retain moisture, and maintain infiltration capacity.*

Planting/Storage Media Design for Nutrient Sensitive Receiving Waters

- 1) Where the BMP discharges to receiving waters with nutrient impairments or nutrient TMDLs, the planting media placed in the cell should be designed with the specific goal of minimizing the potential for initial and long term leaching of nutrients from the media.
- 2) In general, the potential for leaching of nutrients can be minimized by:
 - a. Utilizing stable, aged compost (as required of media mixes under all conditions).
 - b. Utilizing other sources of organic matter, as appropriate, that are safe, non-toxic, and have lower potential for nutrient leaching than compost.
 - c. Reducing the content of compost or other organic material in the media mix to the minimum amount necessary to support vigorous plant growth and healthy biological processes.
- 3) A landscape architect should be consulted to assist in the design of planting/storage media to balance the interests of plant establishment, water retention capacity (irrigation demand), and the potential for nutrient leaching. The following practices should be considered in developing the media mix design:
 - a. The actual nutrient content and organic content of the selected compost source should be considered when specifying the proportions of compost and sand. The compost specification allows a range of organic content over approximately a factor of 2 and nutrient content may vary more widely. Therefore determining the actual organic content and nutrient content of the compost expected to be supplied is important in determining the proportion to be used for amendment.
 - b. A commitment to periodic soil testing for nutrient content and a commitment to adaptive management of nutrient levels can help reduce the amount of organic amendment that must be provided initially. Generally, nutrients can be added planting areas through the addition of organic mulch, but cannot be removed.
 - c. Plant palettes and the associated planting mix should be designed with native plants where possible. Native plants generally have a broader tolerance for nutrient content, and can be longer lived in leaner/lower nutrient soils. An additional benefit of lower nutrient levels is that native plants will generally have less competition from weeds.

- d. Nutrients are better retained in soils with higher cation exchange capacity (CEC). CEC can be increased through selection of organic material with naturally high CEC, such as peat, and/or selection of inorganic material with high CEC such as some sands or engineered minerals (e.g., low P-index sands, zeolites, rhyolites, etc). Including higher CEC materials would tend to reduce the net leaching of nutrients.
- e. Soil structure can be more important than nutrient content in plant survival and biologic health of the system. If a good soil structure can be created with very low amounts of compost, plants survivability should still be provided. Soil structure is loosely defined as the ability of the soil to conduct and store water and nutrients as well as the degree of aeration of the soil. While soil structure generally develops with time, planting/storage media can be designed to promote earlier development of soil structure. Soil structure is enhanced by the use of amendments with high hummus content (as found in well-aged organic material). In addition, soil structure can be enhanced through the use of compost/organic material with a distribution of particle sizes (i.e., a more heterogeneous mix). Finally, inorganic amendments such as polymer beads may be useful for promoting aeration and moisture retention associated with a good soil structure. An example of engineered soil to promote soil structure can be found here:

<http://www.hort.cornell.edu/uhi/outreach/pdfs/custructuralsoilwebpdf.pdf>
- f. Younger plants are generally more tolerant of lower nutrient levels and tend to help develop soil structure as they grow. Starting plants from smaller transplants can help reduce the need for organic amendments and improve soil structure. The project should be able to accept a plant mortality rate that is somewhat higher than starting from larger plants and providing high organic content.
- g. With these considerations, it is anticipated that less than 10 percent compost amendment could be used, while still balancing plant survivability and water retention.

Plants

- 1) Plant materials should be tolerant of summer drought, ponding fluctuations, and saturated soil conditions for 48 to 96 hours.
- 2) It is recommended that a minimum of three types of tree, shrubs, and/or herbaceous groundcover species be incorporated to protect against facility failure due to disease and insect infestations of a single species.
- 3) Native plant species and/or hardy cultivars that are not invasive and do not require chemical inputs should be used to the maximum extent practicable.

Operations and Maintenance

Bioinfiltration areas require annual plant, soil, and mulch layer maintenance to ensure optimum infiltration, storage, and pollutant removal capabilities. In general, bioinfiltration maintenance requirements are typical landscape care procedures and include:

- 1) **Watering:** Plants should be drought-tolerant. Watering may be required during prolonged dry periods after plants are established.
- 2) **Erosion control:** Inspect flow entrances, ponding area, and surface overflow areas periodically, and replace soil, plant material, and/or mulch layer in areas if erosion has occurred (see Appendix I for a bioinfiltration inspection and maintenance checklist). Properly designed facilities with appropriate flow velocities should not have erosion problems, except perhaps in extreme events. If erosion problems occur, the following should be reassessed: (1) flow velocities and gradients within the cell, and (2) flow dissipation and erosion protection strategies in the pretreatment area and flow entrance. If sediment is deposited in the bioinfiltration area, immediately determine the source within the contributing area, stabilize, and remove excess surface deposits.
- 3) **Plant material:** Depending on aesthetic requirements, occasional pruning and removing of dead plant material may be necessary. Replace all dead plants and if specific plants have a high mortality rate, assess the cause and, if necessary, replace with more appropriate species. Periodic weeding is necessary until plants are established. The weeding schedule should become less frequent if the appropriate plant species and planting density have been used and, as a result, undesirable plants excluded.
- 4) **Nutrients and pesticides:** The soil mix and plants should be selected for optimum fertility, plant establishment, and growth. Nutrient and pesticide inputs should not be required and may degrade the pollutant processing capability of the bioinfiltration area, as well as contribute pollutant loads to receiving waters. By design, bioinfiltration facilities are located in areas where phosphorous and nitrogen levels are often elevated and these should not be limiting nutrients. If in question, have soil analyzed for fertility.
- 5) **Mulch:** Replace mulch annually in bioinfiltration facilities where heavy metal deposition is likely (e.g., contributing areas that include industrial and auto dealer/repair parking lots and roads). In residential lots or other areas where metal deposition is not a concern, replace or add mulch as needed to maintain a 2 to 3 inch depth at least once every two years.
- 6) **Soil:** Soil mixes for bioinfiltration facilities are designed to maintain long-term fertility and pollutant processing capability. Estimates from metal attenuation research suggest that metal accumulation should not present an environmental

concern for at least 20 years in bioinfiltration systems. Replacing mulch in bioinfiltration facilities where heavy metal deposition is likely provides an additional level of protection for prolonged performance. If in question, have soil analyzed for fertility and pollutant levels.

RWH-1: Rainwater Harvesting

Rainwater harvesting BMPs capture and store stormwater runoff for later use. These BMPs are engineered to store a specified volume of water with no surface discharge until this volume is exceeded. Storage facilities that can be used to harvest rainwater include cisterns (above ground tanks), open storage reservoirs (e.g., ponds and lakes), and underground storage devices (tanks, vaults, pipes, arch spans, and proprietary storage systems). Uses of captured water may potentially include irrigation demand, indoor non-potable demand, industrial process water demand, or other demands. Rainwater harvesting systems typically include several components: (1) methods to divert runoff to the storage device, (2) an overflow for when the storage device is full, and (3) a distribution system to get the water to where it is intended to be used. Harvesting systems typically include pretreatment to remove large sediment and vegetative debris. Systems used for internal uses may require an additional level of treatment prior to use.

Cistern

Photo Credit: MetaEfficient

Application

- Any type of land use, provided adequate water demand

Preventative Maintenance

- Debris and sediment removal
- After-rain inspections

Limitations

Rainwater harvesting may be used to meet all of the 5% EIA requirement if reliable demand is available. Rainwater harvesting is not required to be used if the available demands do not meet the volume required for 80% capture using a 72 hour drawdown time.

Design Criteria

Specific considerations for cistern rainwater harvesting systems include:

- Cisterns should include screens on gutters and downspouts to remove vegetative debris and sediment from the runoff prior to entering the cistern.
- Above-ground cisterns should be secured in place.
- Above-ground cisterns should not be located on uneven or sloped surfaces; if installed on a sloped surface, the base where the cistern will be installed should be leveled and designed for the weight of the filled cistern prior to installation.
- Child-resistant covers and mosquito screens should be placed on all water entry holes.
- A first flush diverter may be installed so that initial runoff bypasses the cistern. Where a first flush diverter is used, the diverted flows must be directed to a pervious area so that no runoff is produced or another form of treatment must be provided for this flow.
- Above-ground cisterns should be installed in a location with easy access for maintenance or replacement.

Specific considerations for underground detention include:

- Access entry covers (36" diameter minimum) should be locking and within 50 feet of all areas of the detention tank.
- In cases where the detention facility provides sediment containment, the facility should be laid flat and there should be at least 1/2 foot of dead storage within the tank or vault.
- Outlet structures should be designed using the 100-year storm as overflow and should be easily accessible for maintenance activities.
- For detention facilities beneath roads and parking areas, structural requirements should meet H₂O load requirements.
- In cases where groundwater may cause flotation, these forces should be counteracted with backfill, anchors, or other measures.

- Underground detention facilities should be installed on consolidated and stable native soil; if the facility is constructed in fill slopes, a geotechnical analysis should be performed to ensure stability.

General considerations include:

- In cases where there is non-potable indoor demand, proper pretreatment measures should be installed such as pre-filtration, cartridge filtration, and/or disinfection (which can also be provided between the cistern and point of use).
- Plumbing systems should be installed in accordance with the current California Building and Plumbing Codes (CBC – part of California Code of Regulations, Title 24).
- Underground detention facilities can be incorporated into a treatment train to provide initial or supplemental storage to other detention storage facilities and/or infiltration BMPs.
- Treatment of the captured rainwater (i.e. disinfection) may be required depending on the end use of the water.

Rainwater harvesting uses include:

- Harvested rainwater can be used for irrigation and other non-potable uses (if local, State, and Federal ordinances allow). The use of captured stormwater allows a reduced demand on the potable water supply. Cross-contamination should be prevented when make-up water is required for rainwater use demand by providing a backflow prevention system on the potable water supply line and/or an air gap.
- Irrigation Use
 - Subsurface (or drip) irrigation should not require disinfection pretreatment prior to use; other irrigation types, such as spray irrigation, may require additional pre-treatment prior to use
 - Selecting native and/or drought tolerant plants for landscaped area will reduce irrigation demand; however, they are still recommended for use.
- Domestic Use
 - Domestic uses may include toilet flushing and clothes washing (if local, State, and Federal ordinances allow).
 - Pretreatment requirements per local, State, or Federal codes and ordinances may apply.
- Other Non-Potable Uses

- Other potential non-potable uses may include vehicle/equipment washing, evaporative cooling, industrial processes, and dilution water for recycled water systems.

Sizing Criteria

The effectiveness of rainwater harvesting (RWH) systems is a function of tributary area, storage volume, demand patterns and magnitudes, and operational regime. If either of the latter two factors are too complex, simple design criteria metrics are not possible. The rainwater harvesting design criteria provided in this Fact Sheet are intended for the evaluation of systems that have relatively simple demand regimes and passive operation. If the answer to any of the following complexity screening questions is yes, a site-specific evaluation of rainwater harvesting effectiveness should be completed using a continuous simulation model with a long-term precipitation record.

Complexity Screening Questions:

- Does the proposed system have seasonally-varying demand other than irrigation?
- Will the system be operated by advanced control systems or otherwise actively controlled?
- Does the operational regime call for the system be shut down at any time during the rainy season?

Effectiveness of a harvesting system for retaining the SQDV depends on the cistern's effective storage capacity (i.e., the volume available for storage at the beginning of each event). Therefore, the required storage volume varies based on precipitation and demand. Using the following sizing charts, cisterns should be sized to achieve 80 percent capture efficiency. These nomographs are based on continuous simulation performed in EPA SWMM using precipitation and ET records representative of lowland regions (Oxnard Airport Precipitation Gauge, El Rio Spreading Grounds ET station) and mountainous regions (Ojai-Stewart Canyon Precipitation Gauge, Matilja ET Station) of the County.

Instructions for determining required cistern volume and demand are provided below:

Step 1: Determine Required Rainwater Harvesting Design Volume (RWHDV)

Note that a rainwater harvesting system sized for 80% capture runoff (as determined by continuous modeling), which can draw down in 72 hours is required to meet the 5% EIA standard. If the demand required to draw a tank sized for these parameters is not available, rainwater harvesting is not mandated for use. Partial capture of runoff is allowable if rainwater harvesting is desired for use. Sizing instructions for partial capture are included in [Step 3](#).

- 1) Determine the design storm required for 80% capture with a 72 hour drawdown time by selecting the project region (lowland or mountainous), then determining where the 72 hour drawdown curve intersects the 80% capture line. Pivot down from this intersection to the x axis to read the design storm, d_{design} .
- 2) Determine the required rainwater harvesting system volume using the following equation:

$$\text{RWHDV} = C * (d_{\text{design}}/12) * A_{\text{retain}} \quad (\text{Equation 6-19})$$

Where:

- RWHDV = rainwater harvesting design volume (acre-ft)
- C = runoff coefficient, calculated using Appendix E and the site imperviousness
- d_{design} = design storm required for 80% capture with a 72 hour drawdown time, estimated as described in 1) (inches)
- A_{retain} = the drainage area from which runoff must be retained (acres)

Step 2: Determine the Required Daily Demand to Achieve 80% Capture

- 1) The required daily demand to achieve 80% capture of runoff can be calculated as follows:

$$\text{Demand} = [\text{RWHDV}/(72/24)] * (325,851) \quad (\text{Equation 6-20})$$

Where:

- Demand = required project daily demand to draw down rainwater harvesting system sized for 80% capture in 72 hours (gallons)
- RWHDV = rainwater harvesting design volume (acre-ft), from Step 1 above

If the project daily demand is less than the Demand calculated, the project is not required to utilize rainwater harvesting. If rainwater harvesting is desired for use for partial retention, if a longer drawdown time is desired, or if a predetermined daily demand is to be used, refer to Steps 3 and 4 below.

Step 3: Determine RWHDV for Partial Retention or a Longer Drawdown Time

- 1) Calculate RWHDV for selected combination of % capture and drawdown time using nomographs and the following equation:

$$RWHDV = C * (d_{\text{design}}/12) * A_{\text{retain}} \quad (\text{Equation 6-21})$$

Where:

- RWHDV = rainwater harvesting design volume (acre-ft)
- C = runoff coefficient, calculated using Appendix E and the site imperviousness
- d_{design} = design storm required for selected % capture and drawdown time (inches)
- A_{retain} = the drainage area from which runoff must be retained (acres)

- 2) Determine the required daily demand for the selected capture efficiency and/or drawdown time:

$$Demand = [RWHDV / (t_{\text{drawdown}}/24)] * (325,851) \quad (\text{Equation 6-22})$$

Where:

- Demand = required project daily demand to draw down rainwater harvesting system sized for 80% capture in 72 hours (gallons)
- RWHDV = rainwater harvesting design volume (acre-ft), from 1) above
- t_{drawdown} = selected drawdown time (hours)

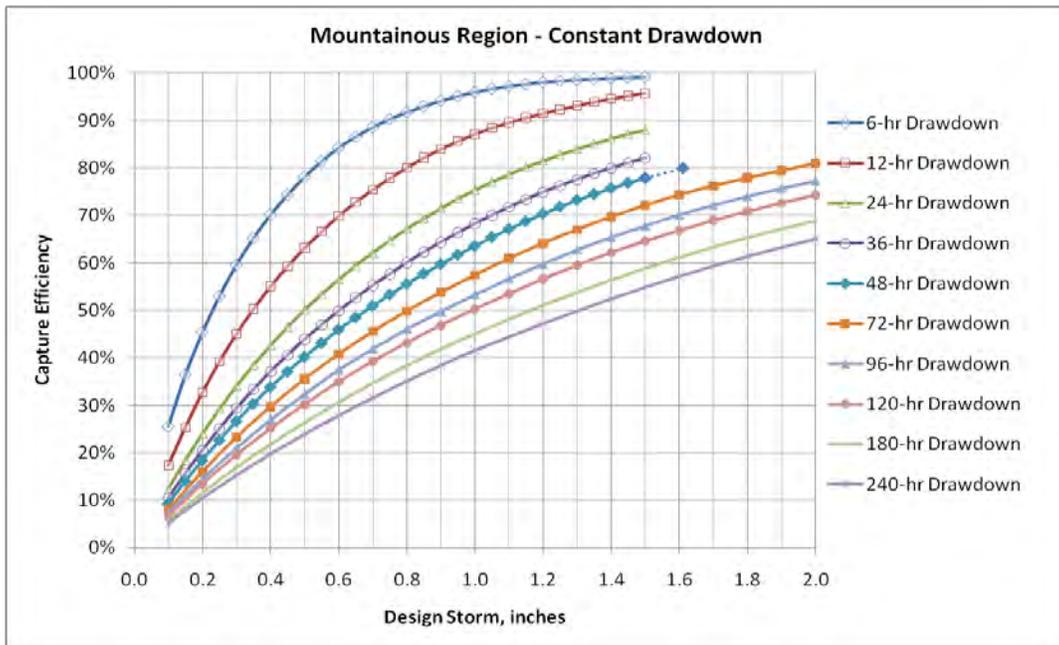

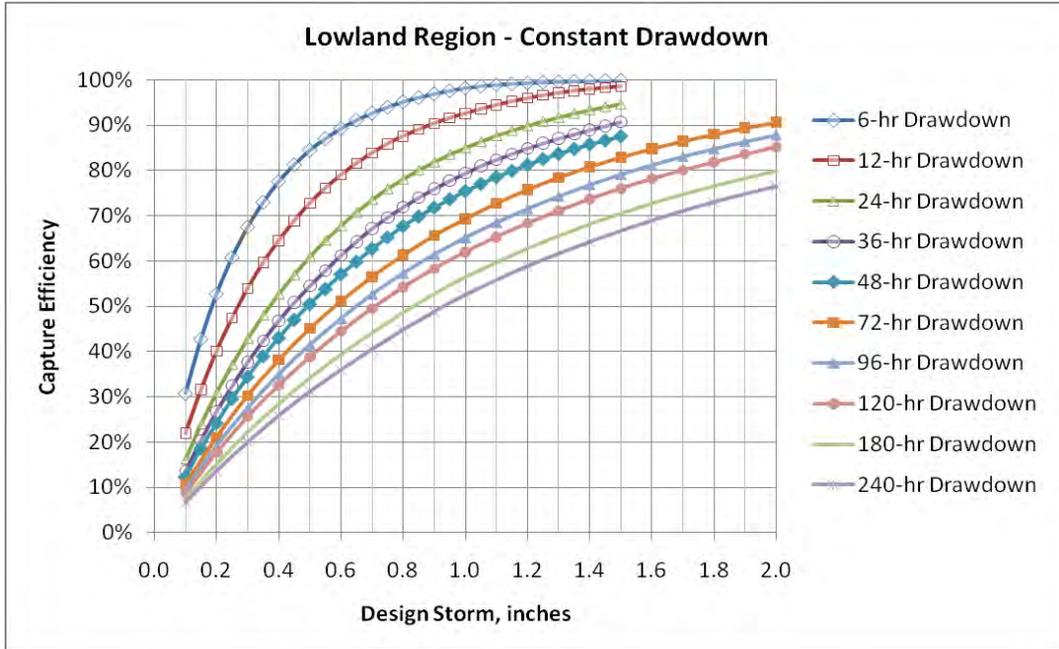

Step 4: Determine RWHDV for a Predetermined Daily Demand

- 1) Determine the daily demand requirement in acre-feet (1 acre-foot = 325,851 gallons).
- 2) Calculate the required RWHDV for the desired drawdown time using the following equation:

$$RWHDV = Demand * (t_{\text{drawdown}}/24) \quad (\text{Equation 6-23})$$

Where:

- Demand = required project daily demand (acre-feet)
- RWHDV = rainwater harvesting design volume (acre-ft)
- t_{drawdown} = selected drawdown time (hours)

Operations and Maintenance

- 1) Inspect storage facilities, associated pipes, and valve connections for leaks.
- 2) Clean gutters and filters of debris that has accumulated and is obstructing flow into the storage facility.
- 3) Clean and remove accumulated sediment annually.
- 4) Check cisterns for stability and anchor if necessary.
- 5) If the storage device is underground, ensure that a manhole is accessible, operational, and secure.

ET-1: Green Roof

Green roofs (also known as eco-roofs and vegetated roof covers) are roofing systems that layer a soil/vegetative cover over a waterproofing membrane. Green roofs rely on highly porous media and moisture retention layers to store intercepted precipitation and to support vegetation that can reduce the volume of stormwater runoff via evapotranspiration. There are two types of green roofing systems: extensive, which is a light-weight system; and intensive, which is a heavier system that allows for larger plants but requires additional structural support.

Green Roof Examples

Photo Credits:

1. Milwaukee Department of Environmental Sustainability;
2. Geosyntec Consultants

Application

- Building roofs
- Outdoor eating area roofs
- Parking structure or turnaround roofs

Preventative Maintenance

- Weeding and pruning
- Leaf and debris removal
- Regular membrane inspection
- Drain cleanout

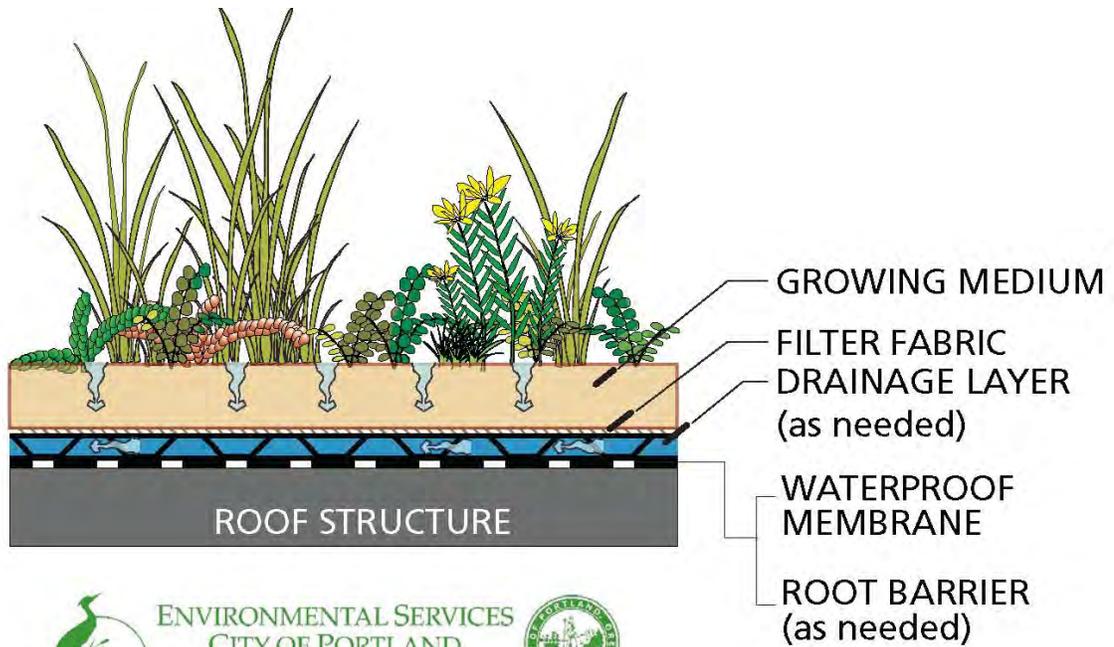

Exhibit A: Green Roof Schematic Courtesy of Portland, OR Environmental Services Department

Exhibit B: Green Roof Schematic Courtesy of American Wick

Figure 6-9: Green Roofs

Limitations

The following describes additional site suitability recommendations and limitations for green roofs.

- Typically not used for steep roofs (>25%); and
- Structural roof support must be sufficient to support additional roof weight.

Design Criteria

Green roofs should be designed according to the requirements listed in Table 6-17 and outlined in the section below.

Table 6-17: Green Roof Design Criteria

Design Parameter	Unit	Design Criteria
Soil depth range	inch	2 – 6
Saturated soil weight	lbs. / sq. ft.	10 – 25
Maximum roof slope	%	25
Minimum roof slope	--	Flat
Vegetation type	--	Varies (see vegetation section below)
Vegetation height	--	Varies (see vegetation section below)

Sizing

Green roofs may provide quantifiable reduction in volume. However, they are not explicitly sized to meet the water quality treatment requirements. Rather, the volume reduction is accounted for implicitly in sizing calculations for the treatment BMPs for the remainder of the site by assuming that the roof area is pervious rather than impervious when calculating a runoff coefficient for the site.

Green Roof Components***Structural Support***

The first requirement that must be met before installing a green roof is the structural support of the roof. The roof must be able to support the additional weight of the soil, water, and vegetation. A licensed structural engineer should be consulted to determine the proposed structural support during the design phase.

Waterproof Roofing Membrane

Waterproof roofing membrane is an integral part of a green roofing system. The waterproof membrane prevents the roof runoff from penetrating and damaging the roofing material. There are many materials available for this purpose and come in various forms (i.e., rolls, sheets, liquid) and exhibit different characteristics (e.g., flexibility, strength, etc.). Depending on the type of membrane chosen a root barrier may be required to prevent roots from compromising the integrity of the membrane.

Drainage Layer

Depending on the design of the roof, a drainage layer may be required to convey the excess runoff from of the roof. If a drainage layer is needed, there are numerous options including a gravel layer (which may require additional structural support), and many styles and types of plastic drainage layers.

Soil Considerations

The soil layer is an important factor in the construction and operation of green roofs. The soil layer must have excellent drainage, not be too heavy when saturated, and be adequately fertile as a growing medium for plants. Many companies sell their own proprietary soil mixes. However, a simple mix of 1/4 topsoil, 1/4 compost, and the remainder pumice perlite may be used for many applications. Other soil amendments may be substituted for the compost and the pumice perlite. The soil mix used should not contain any clay.

Vegetation

Green roofs must be vegetated in order to provide adequate treatment of runoff via filtration and evapotranspiration. Vegetation, when chosen and maintained appropriately, also improves the aesthetics of a site. Green roofs should be vegetated with a mix of erosion-resistant plant species that effectively bind the soil and can withstand the extreme environment of rooftops. A diverse selection of low growing plants that thrive under the specific site, climatic, and watering conditions should be identified. A mixture of drought-tolerant, self-sustaining (perennial or self-sowing without need for fertilizers, herbicides, and or pesticides) is most effective in the Ventura County region. Plants selected should also be low maintenance and able to withstand heat, cold, and high winds. Native or adapted sedum/succulent plants are preferred because they generally require less fertilizer, limited maintenance, and are more drought resistant than exotic plants. When appropriate, green roofs may be planted with larger plants. However, this depends on structural support and soil depth.

The following provides additional vegetation guidance for green roofs.

- 1) For extensive roofs, trees or shrubs may be used as long as the increased soil depth required may be supported.

- 2) Irrigation is required if the seed is planted in spring or summer. The use of a permanent smart (self-regulating) irrigation system or other watering system, may help provide maximal water quality performance. Drought-tolerant plants should be specified to minimize irrigation requirements. For projects seeking “High Performance Building” recognition, ASHRAE Standard 189.1 states that potable water cannot be used for irrigating green roofs after they are established.
- 3) Locate the green roof vegetation in an area without excessive shade to avoid poor vegetative growth. For moderately shaded areas, shade tolerant plants should be used.
- 4) A relevant plant list should be provided by a landscape professional and used as a guide to support project-specific planting recommendations, including recommendations on appropriate plants, fertilizer, mulching applications, and irrigation requirements (if any) to ensure healthy vegetation growth.

Drain

- 1) There must be a drain pipe (gutter) to convey runoff (both overflow and underdrain flow, if appropriate) safely from the roof to another basic or stormwater runoff BMP, a pervious area, or the stormwater conveyance system.

Construction Considerations

- 1) Building structure must be adequate to hold the additional weight of the soil, retained water, and plants.
- 2) Plants should be selected carefully to minimize maintenance and function properly.

Operations and Maintenance

- 1) During the establishment period, green roofs may need irrigation and occasional light fertilization until the plants have fully established themselves. Once healthy and fully established, properly selected climate-appropriate plants will no longer need irrigation except during extreme drought.
- 2) Weeding during the establishment period may be required to ensure proper establishment of the desired vegetation. Once established and assuming proper selection of vegetation, the vegetation should not require any preventative maintenance.
- 3) The roofing membrane should be inspected routinely, as it is a crucial element of the green roof. In addition, preventative inspection of the drainage paths is required to ensure that there are no clogs in the system. If a green roof is not properly draining, the moisture in the system may cause the roof to leak and/or the plants to drown or rot. Leaks in the roof may occur not only due to improper drainage, but also if the incorrect combination of waterproofing barrier, root barrier, and drainage systems

- are selected. Leak inspections in the roofing system are advised, especially in locations prone to leaks, such as at all joints.
- 4) Inspect green roofs for erosion or damage to vegetation after every storm greater than 0.75 inches and at the end of the wet season to schedule summer maintenance and in the fall to ensure readiness for winter. Additional inspection after periods of heavy runoff is recommended. Green roofs should be checked for debris, litter, and signs of clogging.
 - 5) Replanting and/or reseeding of vegetation may be required for reestablishment.
 - 6) Vegetation should be healthy and dense enough to provide filtering while protecting underlying soils from erosion.
 - 7) Fallen leaves and debris from deciduous plant foliage should be removed.
 - 8) Invasive vegetation, such as Alligatorweed (*Alternanthera philoxeroides*), Halogeton (*Halogeton glomeratus*), Spotted Knapweed (*Centaurea maculosa*), Giant Reed (*Arundo donax*), Castor Bean (*Ricinus communis*), Perennial Pepperweed (*Lepidium latifolium*), and Yellow Starthistle (*Centaurea solstitialis*) should be removed and replaced with non-invasive species. For more information on invasive weeds, including biology and control of listed weeds, look at the [encycloweedia](#) located at the California Department of Food and Agriculture website or the California Invasive Plant Council website at www.cal-ipc.org.
 - 9) Dead vegetation should be removed if greater than 10% of the area coverage. Vegetation should be replaced and established before the wet season to maintain cover density and control erosion where soils are exposed.

ET-2: Hydrologic Source Control BMPs

Hydrologic source control (HSC) BMPs are simple BMPs that are highly integrated with the site design to reduce runoff volume. The practices described in this fact sheet include impervious area dispersion, street trees, and rain barrels.

Application

- Building roofs
- Sidewalks and patios
- Landscaping hardscapes

Preventative Maintenance

- Weeding and pruning
- Leaf and debris removal

Hydrologic Source Control Examples

Accounting for Hydrologic Source Controls in Hydrologic Calculations

The effects of HSC BMPs are accounted for in hydrologic calculations as an adjustment to the storm depth used in the SQDV calculations described in [Section 2](#). Runoff volume calculations are performed exactly as described in Section 2, with the exception that the storm depth used in the calculation is adjusted prior to the calculation. Adjustments are based on the type and magnitude of HSC BMPs employed for the drainage area per guidance outlined in this Fact Sheet.

EXAMPLE 6.1: ACCOUNTING FOR HSCS IN HYDROLOGIC CALCULATIONS

Given:

- A drainage area consists of a 1 acre building roof surrounded by 0.25 acres of landscaping (80 percent composite imperviousness);
- The drainage from the roof is spread uniformly over the entire pervious area via splash pads and level spreaders;
- Soils are moderately well drained and have a shallow slope;
- For the purpose of this example, assume the hydrologic source control adjustment for this configuration of disconnected downspouts is 0.3 inches. For an actual project, hydrologic source control adjustment would be calculated based on instructions in this section; and
- The unadjusted design storm depth at the project site is 0.75 inches.

Result:

- 1) The designer uses 0.75 inches – 0.3 inches = 0.45 inches in the calculation of SQDV.

Impervious Area Dispersion

Impervious area dispersion refers to the practice of routing runoff from impervious areas, such as rooftops, walkways, and patios, onto the surface of adjacent pervious areas. Runoff is dispersed uniformly via splash block or dispersion trench and soaks into the ground as it moves slowly across the surface of the pervious area. Minor ponding may occur, but it is not the intent of this practice to actively promote localized on-lot infiltration, which should be designed as an infiltration BMP (see INF-1 through INF-6 above).

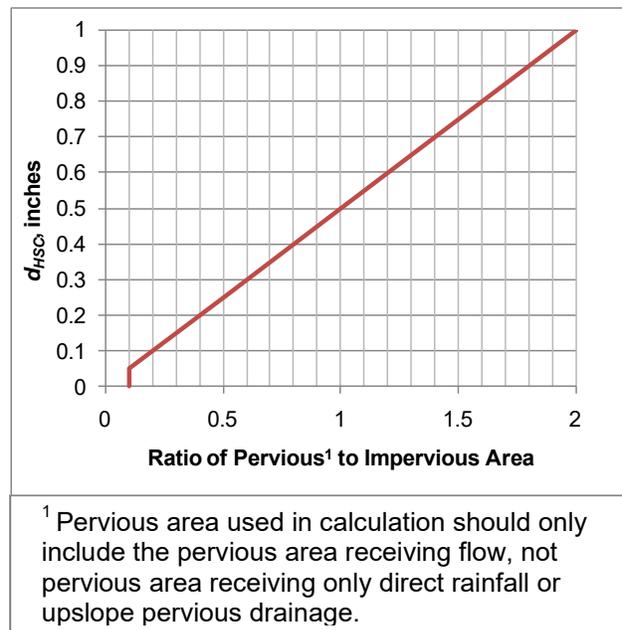

Design Considerations

- 1) Not likely to result in net increased infiltration over existing condition for previously pervious sites, but has potential to result in some geotechnical hazards associated with infiltration.
- 2) Significant pervious area should be available, at a ratio of at least 1 part pervious area capable of receiving flow to 5 parts impervious.

- 3) Pervious area receiving flow should have a slope ≤ 2 percent and path lengths of ≥ 10 feet per 1000 sf of impervious area.
- 4) Overflow from the pervious area up to the SQDV should be directed to a Retention BMP, Biofiltration BMP, or Treatment Control Measure. Larger flows should be directed to the storm drain system.
- 5) Soils in the pervious area should be preserved in their natural condition or improved with soil amendments (see Soil Amendments below).
- 6) Impervious area disconnection is an HSC that may be used as the first element in any treatment train.
- 7) The use of impervious area disconnection reduces the sizing requirement for downstream Retention BMPs, Biofiltration BMPs, and/or Treatment Control Measures.

Calculating HSC Retention Volume

- 1) The retention volume provided by downspout dispersion is a function of the ratio of impervious to pervious area.
- 2) Determine flow patterns in pervious area and estimate footprint of pervious area receiving dispersed flow. Calculate the ratio of pervious to impervious area.
- 3) Check soil conditions using the checklist below; amend if necessary.
- 4) Look up the storm retention depth (d_{HSC}), from the chart to the right.

- 5) The max d_{HSC} is equal to the design storm depth for the project site.

Soil Condition Checklist

- 1) Soil should have a maximum slope of 2 percent.
- 2) Landscaping should be well-established.
- 3) Amended soils should consist of: 60 to 70% sand, 15 to 25% compost, 10 to 20% clean topsoil. The organic content of the soil mixture should be 8 to 12%; the pH range should be 5.5 to 7.5.

Amended Soils

A soil amendment is any material added to the upper layer of soil especially in the vicinity of the root zone soil to improve its physical properties, such as the water retention, permeability, water infiltration, drainage, aeration and structure. The goal is to provide a better environment for roots. To do its work, an amendment should be thoroughly mixed into the soil. If it is merely buried, its effectiveness is reduced and it will interfere with water and air movement and root growth.

Amending a soil is different from mulching, although many mulches also are used as amendments. A mulch is left on the soil surface. Its purpose is to reduce evaporation and runoff, inhibit weed growth, and create an attractive appearance. Mulches also moderate soil temperature, helping to warm soils in the spring and cool them in the summer. Mulches may be incorporated into the soil as amendments after they have decomposed to the point that they no longer serve their purpose.

Organic amendments, such as compost, increase soil organic matter content and offer many benefits. Organic matter improves soil aeration, water infiltration, and both water- and nutrient-holding capacity. Many organic amendments contain plant nutrients and act as organic fertilizers. Organic matter also is an important energy source for bacteria, fungi and earthworms that live in the soil.

Design Considerations

- 1) Landscaped and other developed pervious areas can be amended to improve evapotranspiration and soil moisture storage capacity.
- 2) Landscape and other developed pervious areas can be amended to increase infiltration rates in cases where the limiting infiltration horizon exists near the surface of the soil column.

- 3) Soil amendments are common components of several Retention BMPs, Biofiltration BMPs, and Treatment Control Measures, including infiltration basins, bioretention, vegetated swales, filter strips, planter boxes, green roofs, dry extended detention basins, wet retention basins, and constructed treatment wetlands.
- 4) Compost, soil conditioners, and fertilizers should be rototilled into the native soil to a minimum depth of 6 inches; 12 inches preferred.
- 5) All soil amendments shall be free of sticks, glass, plastic, metal, debris larger than 1 inch, and other deleterious material.
- 6) Compost shall meet criteria listed in the guidelines for planting and storage media.

Calculating HSC Retention Volume

No retention credit is given for amended soils alone. Amended soils should be used to increase the retention volume of Retention BMPs, Biofiltration BMPs, and Treatment Control Measures.

<http://www.ext.colostate.edu/pubs/garden/07235.html>

Street Trees

By intercepting rainfall, trees can provide several aesthetic and stormwater benefits including peak flow control, increased infiltration and evapotranspiration, and runoff temperature reduction. The volume of precipitation intercepted by the canopy reduces the treatment volume required for downstream treatment BMPs. Shading reduces the heat island effect as well as the temperature of adjacent impervious surfaces over which stormwater flows, and thus reduces the heat transferred to the downstream waterbody. Tree roots also strengthen the soil structure and provide infiltrative pathways, simultaneously reducing erosion potential and enhancing infiltration.

Design Considerations

- 1) Street trees can be incorporated along sidewalks, streets, parking lots, or driveways.
- 2) Street trees can be used in combination with bioretention systems along medians or in traffic calming bays.
- 3) There should be sufficient space available to accommodate both the tree canopy and the root system.

- 4) The mature tree canopy, height, and root system should not interfere with subsurface utilities, overhead powerlines, buildings and foundations, or other existing or planned structures.
- 5) Depending on space constraints, a 20 to 30 foot canopy (at maturity) is recommended for stormwater mitigation.
- 6) Native, drought-tolerant species should be selected in order to minimize irrigation requirements and improve the long-term viability of the tree.
- 7) Trees should not impede pedestrian or vehicle sight lines.
- 8) Planting locations should receive adequate sunlight and wind protection. Other environmental factors should be considered prior to planting.
- 9) Soils should be preserved in their natural condition (if appropriate for planting) or restored via soil amendments. If necessary, a landscape architect should be consulted.

Calculating HSC Retention Volume

- 1) The retention volume provided by streets trees via canopy interception is dependent on the tree species, time of the year, and maturity.
- 2) To compute the retention credit, the expected impervious area covered by the full tree canopy after 4 years of growth should be computed (IA_{HSC}). The maximum retention depth credit for canopy interception (d_{HSC}) is 0.05 inches.

Residential Rain Barrels

Rain barrels are above ground storage vessels that capture runoff from roof downspouts during rain events and detain that runoff for later use for irrigating landscaped areas.

Design Considerations

- 1) If detained water will be used for irrigation, sufficient vegetated areas and other impervious surfaces should be present in the drainage area.
- 2) Storage capacity and sufficient area for overflow dispersion should be accounted for.
- 3) Screens on gutters and downspouts to remove sediment and particles as the water enters the barrel or cistern should be provided.
- 4) Removable child-resistant covers and mosquito screening should be provided to prevent unwanted access.
- 5) Above-ground barrels should be secured in place.
- 6) Above-ground barrels should not be located on uneven or sloped surfaces. If installed on a sloped surface, the base where the rain barrel will be installed should be leveled prior to installation.
- 7) Overflow dispersion should occur greater than 5 feet from building foundations.
- 8) Dispersion should not cause geotechnical hazards related to slope stability.
- 9) Effective energy dissipation and uniform flow spreading methods should be employed to prevent erosion and facilitate dispersion.
- 10) Placement should allow easy access for regular maintenance.

*Calculating HSC Retention Volume*

- 1) The retention volume provided by rain barrels that are not actively managed can be computed as 50% of the total storage volume (e.g., 22.5 gallons for each 55 gallon barrel).
- 2) If the rain barrel is actively managed, then it should be treated as a cistern (see RWH-1).
- 3) Estimate the average retention volume per 1000 square feet impervious tributary area provided by rain barrels.
- 4) Look up the storm retention depth (d_{HSC}), from the chart to the right.
- 5) The max d_{HSC} is equal to the design storm depth for the project site.

BIO-1: Bioretention with Underdrain

Bioretention stormwater treatment facilities are landscaped shallow depressions that capture and filter stormwater runoff. These facilities function as a soil and plant based filtration device that removes pollutants through a variety of physical, biological, and chemical treatment processes. The facilities normally consist of a ponding area, mulch layer, planting soils, and plantings. As stormwater passes down through the planting soil, pollutants are filtered, adsorbed, and biodegraded by the soil and plants. Bioretention with an underdrain is a treatment control measures that can be used for areas with low permeability native soils or steep slopes. Bioretention may be designed without an underdrain to serve as a retention BMP in areas of high soil permeability (see [INF-3 Bioretention](#)) or partial retention/ partial biofiltration BMP (see [INF-7: Bioinfiltration](#)).

Bioretention in Parking Lots

Photo Credits: Geosyntec Consultants

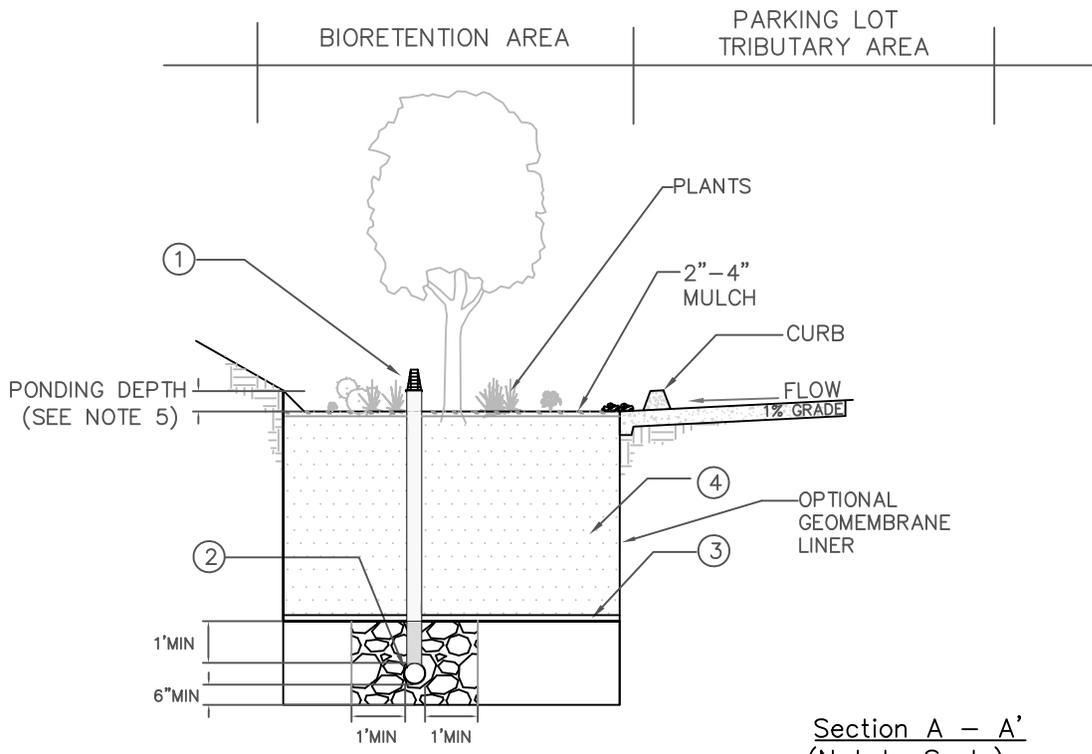

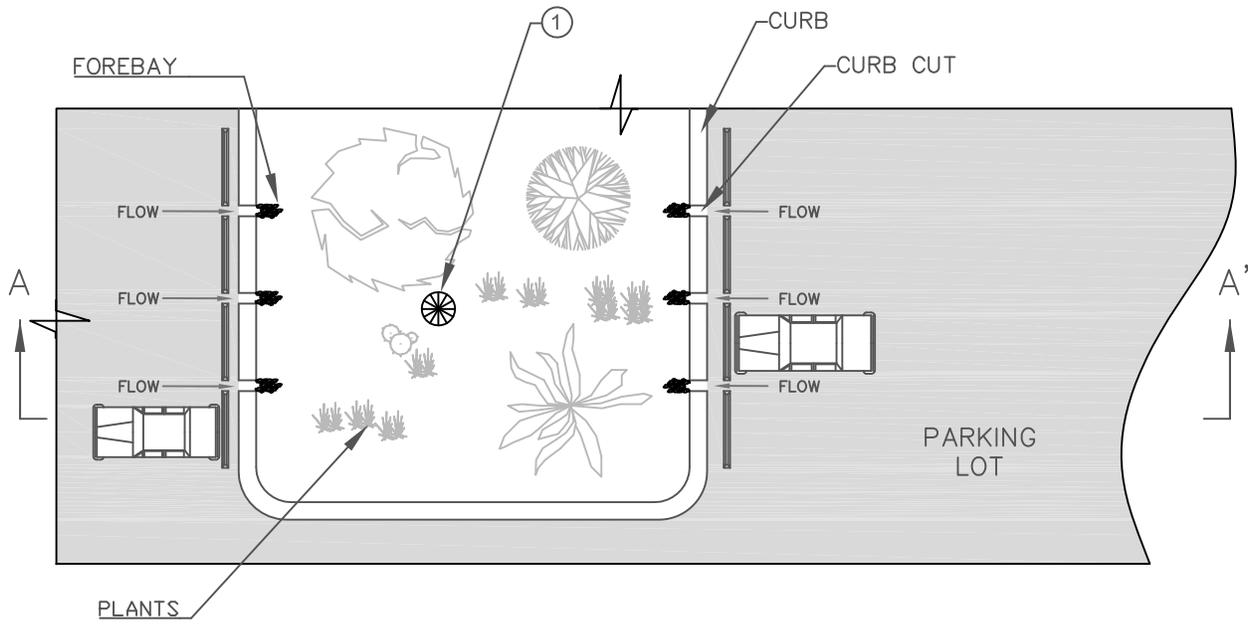

Application

- Parking lots
- Roadway parkways and medians
- School entrances, courtyards, and walkways
- Playgrounds and sports fields

Preventative Maintenance

- Repair small eroded areas
- Remove trash and debris and rake surface soils
- Remove accumulated fine sediments, dead leaves, and trash
- Remove weeds and prune back excess plant growth
- Remove sediment and debris accumulation near inlet and outlet structures
- Periodically observe function under wet weather conditions

Plan View
(Not to Scale)

NOTES:

- ① OVERFLOW DEVICE: VERTICAL RISER OR EQUIVALENT.
- ② PERFORATED 6" MIN PVC PIPE UNDERDRAIN.
- ③ OPTIONAL CHOKING GRAVEL LAYER.
- ④ 2' MIN PLANTING MIX; 3' PREFERRED.
- ⑤ PONDING DEPTH 18" WITH FENCE; 6" WITHOUT FENCE.

Section A - A'
(Not to Scale)

<p>Figure 6-10: Bioretention with Underdrain</p>

Limitations

- 1) Vertical relief and proximity to storm drain - site must have adequate relief between land surface and storm drain to permit vertical percolation through the soil media and collection and conveyance in underdrain to storm drain system.
- 2) Depth to groundwater - shallow groundwater table may not permit complete drawdown between storms.

Design Criteria

Bioretention with an underdrain should be designed according to the requirements listed in Table 6-18 and outlined in the section below. BMP sizing worksheets are presented in Appendix E.

Table 6-18: Bioretention with an Underdrain Design Criteria

Design Parameter	Unit	Design Criteria
Stormwater quality design volume (SQDV)	acre-feet	See Section 2 and Appendix E for calculating SQDV.
Forebay	-	Forebay should be provided for all tributary surfaces that contain landscaped areas. Forebays should be designed to prevent standing water during dry weather and should be planted with a plant palette that is tolerant of wet conditions.
Maximum drawdown time of water ponded on surface	hours	72
Maximum drawdown time of surface ponding plus subsurface pores	hours	96 (72 preferred)
Maximum ponding depth	inches	18 inches
Minimum thickness of amended soils layer	feet	2 (3 preferred)
Minimum thickness of stabilized mulch	inches	2 to 4
Planting mix composition	-	60 to 80% fine sand, 20 to 40% compost
Underdrain sizing	-	6 inch minimum diameter; 0.5% minimum slope; slotted, polyvinyl chloride (PVC) pipe (PVC SDR 35 or approved equivalent); spacing shall be determined to provide

Design Parameter	Unit	Design Criteria
		capacity for maximum rate filtered through amended media
Gravel layer	-	A gravel bed should be provided around underdrain. Underdrain should have at least 1 foot of gravel installed to the sides and on top of the underdrain, and at least 0.5 feet of gravel installed below underdrain.
Overflow device	-	Required

Sizing Criteria

Bioretention facilities with underdrains shall be designed to capture and treat the SQDV. However because these systems commonly have a relatively high amended soil infiltration rate and shallow depth, these systems are typically capable of filtering a significant portion of the SQDV during a storm event. Therefore, a simplified routing approach is described in the following steps that accounts for the portion of the SQDV that is filtered during the storm event.

Step 1: Calculate the Design Volume

Bioretention facilities shall be sized to capture and biofilter the SQDV (see Section 2.3 and Appendix E).

Step 2: Determine the Design Percolation Rate

Sizing is based on the design saturated hydraulic conductivity (K_{sat}) of the amended soil layer. A target K_{sat} of 5 inches per hour is recommended for non-proprietary amended soil media. The media K_{sat} will decline between maintenance cycles as the surface becomes occluded and particulates accumulate in the amended soil layer. A factor of safety of 2.0 should be applied such that the resulting recommended design K_{sat} is 2.5 inches per hour. This value should be used for sizing unless sufficient rationale is provided to justify a higher design K_{sat} .

Step 3: Calculate the surface area

Determine the size of the required infiltrating surface by assuming the SQDV will fill the available ponding depth plus the void spaces in the media, based on the computed porosity of the filter media and aggregate layer.

- 1) Select a surface ponding depth (d_p) that satisfies geometric criteria and is congruent with the constraints of the site. Selecting a deeper ponding depth (18 inches maximum) generally yields a smaller footprint, however, it requires greater consideration for public safety, energy dissipation, and plant selection.
- 2) Compute time for selected ponding depth to filter through media:

$$t_{ponding} = \frac{d_p}{K_{design}} 12 \frac{in}{ft} \quad (\text{Equation 6-24})$$

Where:

- $t_{ponding}$ = required drain time of surface ponding (≤ 72 hrs)
- d_p = selected surface ponding water depth (ft)
- K_{design} = media design saturated hydraulic conductivity (in/hr)
(see Step 2, above)

If $t_{ponding}$ exceeds 72 hours, return to (1) and reduce surface ponding or increase media K_{design} . Otherwise, proceed to next step.

Note: In nearly all cases, $t_{ponding}$ will not approach 72 hours unless a low K_{design} is specified.

- 3) Compute depth of water that may be filtered during the design storm event as follows:

$$d_{filtered} = \text{Minimum} \left[\frac{K_{design} \times T_{routing}}{12 \frac{in}{ft}}, d_p \right] \quad (\text{Equation 6-25})$$

Where:

- $d_{filtered}$ = depth of water that may be considered to be filtered during the design storm event (ft) for routing calculations; this value should not exceed the surface ponding depth (d_p)
- K_{design} = design saturated hydraulic conductivity (in/hr) (see Step 2, above)
- $T_{routing}$ = storm duration that may be assumed for routing calculations; this should be assumed to be 3 hours unless rationale for an alternative assumption is provided
- d_p = selected surface ponding water depth (ft)

The intention is that routing is important in the appropriate sizing of bioretention with underdrains. However, the depth of water considered to be filtered during the storm should be limited to the maximum ponding depth. This

results in designs that are robust to account for a variety of storm depths and durations. This limitation is for sizing calculations only. In reality, the depth that is filtered during a storm will vary based on storm depth, duration, and intensity. This TGM does not intend to limit the amount that may actually be filtered.

- 4) Calculate required infiltrating surface area (filter bottom area):

$$A_{req} = \frac{SQDV}{d_p + d_{filtered}} \quad \text{(Equation 6-26)}$$

Where:

- A_{req} = required infiltrating area (ft²). Should be calculated at the contour corresponding to the mid ponding depth (i.e., 0.5× d_p from the bottom of the facility)
- $SQDV$ = stormwater quality design volume (ft³)
- d_p = selected surface ponding water depth (ft)
- $d_{filtered}$ = depth of water that can be considered to be filtered during the design storm event (ft) for routing calculations (See Equation 6-15)

- 5) Calculate total footprint required by including a buffer for side slopes and freeboard; A_{req} is calculated at the contour corresponding to the mid ponding depth (i.e., 0.5× d_p from the bottom of the facility).

Geometry

- 1) Minimum planting soil depth should be 2 feet, although 3 feet is preferred.

The intention is that the minimum planting soil depth should provide a beneficial root zone for the chosen plant palette and adequate water storage for the stormwater quality design volume. A deeper soil depth will provide a smaller surface area footprint.

- 2) Bioretention should be designed to drain below the planting soil in less than 72 hours and completely drain from the underdrain in 96 hours (both starting from the end of inflow).

The intention is that soils must be allowed to dry out periodically in order to restore hydraulic capacity to receive flows from subsequent storms, maintain infiltration rates, maintain adequate soil oxygen levels for healthy soil biota and vegetation, and to provide proper soil conditions for biodegradation and retention of pollutants.

Flow Entrance and Energy Dissipation

The following types of flow entrance can be used for bioretention cells:

- 1) Dispersed, low velocity flow across a landscape area. Dispersed flow may not be possible given space limitations or if the facility is controlling roadway or parking lot flows where curbs are mandatory.
- 2) Dispersed flow across pavement or gravel and past wheel stops for parking areas.
- 3) Curb cuts for roadside or parking lot areas: Curb cuts should include rock or other erosion protection material in the channel entrance to dissipate energy. Flow entrance should drop 2 to 3 inches from curb line and provide an area for settling and periodic removal of sediment and coarse material before flow dissipates to the remainder of the cell.
- 4) Pipe flow entrance: Piped entrances, such as roof downspouts, should include rock, splash blocks, or other appropriate measures at the entrance to dissipate energy and disperse flows.
- 5) Woody plants (trees, shrubs, etc.) can restrict or concentrate flows and can be damaged by erosion around the root ball and should not be placed directly in the entrance flow path.

Underdrains

Underdrains should meet the following criteria:

- 1) 6-inch minimum diameter.
- 2) Underdrains should be made of slotted, polyvinyl chloride (PVC) pipe (PVC SDR 35 or approved equivalent). *The intention is that compared to round-hole perforated pipe, slotted underdrains provide greater intake capacity, clog resistant drainage, and reduced entrance velocity into the pipe, thereby reducing the chances of solids migration.*
- 3) Slotted pipe should have 2 to 4 rows of slots cut perpendicular to the axis of the pipe or at right angles to the pitch of corrugations. Slots should be 0.04 to 0.1 inches and should have a length of 1 to 1.25 inches. Slots should be longitudinally spaced such that the pipe has a minimum of one square inch of slot per lineal foot of pipe and should be placed with slots facing the bottom of the pipe.
- 4) Underdrains should be sloped at a minimum of 0.5%.
- 5) Rigid non-perforated observation pipes with a diameter equal to the underdrain diameter should be connected to the underdrain every 100 feet to provide a clean-out port as well as an observation well to monitor dewatering rates. The wells/cleanouts should be connected to the perforated underdrain with the appropriate manufactured connections. The wells/cleanouts should extend 6 inches above the top

elevation of the bioretention facility mulch, and should be capped with a lockable screw cap. The ends of the underdrain pipes not terminating in an observation well/cleanout should also be capped.

- 6) The following aggregate should be used to provide a gravel blanket and bedding for the underdrain pipe. Place the underdrain on a bed of washed aggregate at a minimum thickness of 6 inches and cover it with the same aggregate to provide a 1 foot minimum depth around the top and sides of the slotted pipe.

Sieve size	Percent Passing
¾ inch	100
¼ inch	30-60
US No. 8	20-50
US No. 50	3-12
US No. 200	0-1

- 7) At the option of the designer/geotechnical engineer, a geotextile fabric may be placed between the planting media and the drain rock. If a geotextile fabric is used, it should meet a minimum permittivity rate of 75 gal/min/ft², should not impede the infiltration rate of the soil medium, and should meet the following minimum materials requirements.

Geotextile Property	Value	Test Method
Trapezoidal Tear (lbs)	40 (min)	ASTM D4533
Permeability (cm/sec)	0.2 (min)	ASTM D4491
AOS (sieve size)	#60 - #70 (min)	ASTM D4751
Ultraviolet resistance	70% or greater	ASTM D4355

Preferably, aggregate should be used in place of filter fabric to reduce the potential for clogging. This aggregate layer should consist of 2 to 4 inches of washed sand underlain with 2 inches of choking stone (Typically #8 or #89 washed).

- 8) For bioretention facilities enhanced to remove address nitrogen as the primary pollutant class, the underdrain should be elevated from the bottom of the bioretention facility by at least 6 inches within the gravel blanket to create a fluctuating anaerobic/aerobic zone below the drain pipe. *The intention is that denitrification within the anaerobic/anoxic zone is facilitated by microbes using forms of nitrogen (NO₂ and NO₃) instead of oxygen for respiration.*

An alternative enhanced nitrogen removal design is to include an internal water storage layer by adding a 90-degree elbow to the underdrain to raise the outlet. This design feature provides additional storage in the media. The bioretention facility must have at least 30 inches of planting media. The top of the elbow should be at

least 12 inches below the top of the planting media, and in poorly draining soils, should preferably be 18 to 24 inches below the top of the planting media. The top of the water storage layer should not be less than 12 inches from the bottom of the planting media layer. (For more information, see [Urban Waterways](#) publication).

- 9) The underdrain should drain freely to an acceptable discharge point. The underdrain can be connected to a downstream open conveyance (vegetated swale), to another bioretention cell as part of a connected treatment system, to a storm drain, daylight to a vegetated dispersion area using an effective flow dispersion device, or to a storage facility for rainwater harvesting.

Overflow

An overflow device is required at the maximum ponding depth. The following, or equivalent, should be provided:

- 1) A vertical PVC pipe (SDR 35) should be connected to the underdrain.
- 2) The overflow riser(s) should be 6 inches or greater in diameter, so it can be cleaned without damage to the pipe. The vertical pipe will provide access to cleaning the underdrains.
- 3) The inlet to the riser should be at the ponding depth (maximum 18 inches for fenced bioretention areas and 6 inches for areas that are not fenced), and be capped with a spider cap to exclude floating mulch and debris. Spider caps should be screwed in or glued (i.e., not removable).

Hydraulic Restriction Layers

Infiltration pathways may need to be restricted due to the close proximity of roads, foundations, or other infrastructure. A geomembrane liner, or other equivalent water proofing, may be placed along the vertical walls to reduce lateral flows. This liner should have a minimum thickness of 30 mils.

Planting/Storage Media

- 1) The planting media placed in the cell should achieve a long-term, in-place infiltration rate of at least 1 inch per hour. Higher infiltration rates are permissible. If the design long-term, in-place infiltration rate of the soil exceeds 12 inches per hour, documentation should be provided to demonstrate that the media will adequately address pollutants of concern at a higher flowrate. Bioretention soil shall also support vigorous plant growth.
- 2) Planting media should consist of 60 to 80% fine sand and 20 to 40% compost.
- 3) Sand should be free of wood, waste, coating such as clay, stone dust, carbonate, etc., or any other deleterious material. All aggregate passing the No. 200 sieve size should be non-plastic. Sand for bioretention should be analyzed by an accredited lab using

#200, #100, #40, #30, #16, #8, #4, and 3/8 sieves (ASTM D 422 or as approved by the local permitting authority) and meet the following gradation (Note: all sands complying with ASTM C33 for fine aggregate comply with the gradation requirements below):

Sieve Size (ASTM D422)	% Passing (by weight)	
	Minimum	Maximum
3/8 inch	100	100
#4	90	100
#8	70	100
#16	40	95
#30	15	70
#40	5	55
#100	0	15
#200	0	5

Note: the gradation of the sand component of the media is believed to be a major factor in the hydraulic conductivity of the media mix. If the desired hydraulic conductivity of the media cannot be achieved within the specified proportions of sand and compost (#2), then it may be necessary to utilize sand at the coarser end of the range specified in above (“minimum” column).

- 4) Compost should be a well decomposed, stable, weed free organic matter source derived from waste materials including yard debris, wood wastes, or other organic materials not including manure or biosolids meeting standards developed by the US Composting Council (USCC). The product shall be certified through the USCC Seal of Testing Assurance (STA) Program (a compost testing and information disclosure program). Compost quality should be verified via a lab analysis to be:
 - Feedstock materials shall be specified and include one or more of the following: landscape/yard trimmings, grass clippings, food scraps, and agricultural crop residues.
 - Organic matter: 35-75% dry weight basis.
 - Carbon and Nitrogen Ratio: 15:1 < C:N < 25:1
 - Maturity/Stability: shall have dark brown color and a soil-like odor. Compost exhibiting a sour or putrid smell, containing recognizable grass or leaves, or is hot (120 F) upon delivery or rewetting is not acceptable.
 - Toxicity: any one of the following measures is sufficient to indicate non-toxicity:
 - $NH_4:NH_3 < 3$
 - Ammonium < 500 ppm, dry weight basis

- Seed Germination > 80% of control
- Plant trials > 80% of control
- Solvita® > 5 index value
- Nutrient content:
 - Total Nitrogen content 0.9% or above preferred
 - Total Boron should be <80 ppm, soluble boron < 2.5 ppm
- Salinity: < 6.0 mmhos/cm
- pH between 6.5 and 8 (may vary with plant palette)

Compost for bioretention should be analyzed by an accredited lab using #200, 1/4 inch, 1/2 inch, and 1 inch sieves (ASTM D 422 or as approved by the local permitting authority) and meet the following gradation:

Sieve Size (ASTM D422)	% Passing (by weight)	
	Minimum	Maximum
1 inch	99	100
1/2 inch	90	100
1/4 inch	40	90
#200	2	10

Tests should be sufficiently recent to represent the actual material that is anticipated to be delivered to the site. If processes or sources used by the supplier have changed significantly since the most recent testing, new tests should be requested.

Note: the gradation of compost used in bioretention media is believed to play an important role in the saturated hydraulic conductivity of the media. To achieve a higher saturated hydraulic conductivity, it may be necessary to utilize compost at the coarser end of this range (“minimum” column). The percent passing the #200 sieve (fines) is believed to be the most important factor in hydraulic conductivity.

In addition, a coarser compost mix provides more heterogeneity of the bioretention media, which is believed to be advantageous for more rapid development of soil structure needed to support health biological processes. This may be an advantage for plant establishment with lower nutrient and water input.

- 5) The bioretention area should be covered with 2 to 4 inches (average 3 inches) of mulch at the start and an additional placement of 1 to 2 inches of mulch should be added annually. *The intention is that to help sustain the nutrient levels, suppress weeds, retain moisture, and maintain infiltration capacity.*

Plants

Plant materials should be tolerant of summer drought, ponding fluctuations, and saturated soil conditions for 48 to 96 hours.

It is recommended that a minimum of three types of tree, shrubs, and/or herbaceous groundcover species be incorporated to protect against facility failure due to disease and insect infestations of a single species.

Native plant species and/or hardy cultivars that are not invasive and do not require chemical inputs should be used to the maximum extent practicable.

Operations and Maintenance

Bioretention areas require annual plant, soil, and mulch layer maintenance to ensure optimum infiltration, storage, and pollutant removal capabilities. In general, bioretention maintenance requirements are typical landscape care procedures and include:

- 1) **Watering:** Plants should be selected to be drought-tolerant and not require watering after establishment (2 to 3 years). Watering may be required during prolonged dry periods after plants are established.
- 2) **Erosion control:** Inspect flow entrances, ponding area, and surface overflow areas periodically, and replace soil, plant material, and/or mulch layer in areas if erosion has occurred (see Appendix I for a bioretention inspection and maintenance checklist). Properly designed facilities with appropriate flow velocities should not have erosion problems except perhaps in extreme events. If erosion problems occur, the following should be reassessed: (1) flow velocities and gradients within the cell, and (2) flow dissipation and erosion protection strategies in the pretreatment area and flow entrance. If sediment is deposited in the bioretention area, immediately determine the source within the contributing area, stabilize, and remove excess surface deposits.
- 3) **Plant material:** Depending on aesthetic requirements, occasional pruning and removing of dead plant material may be necessary. Replace all dead plants and if specific plants have a high mortality rate, assess the cause and, if necessary, replace with more appropriate species. Periodic weeding is necessary until plants are established. The weeding schedule should become less frequent if the appropriate plant species and planting density have been used and, as a result, undesirable plants have been excluded.
- 4) **Nutrient and pesticides:** The soil mix and plants are selected for optimum fertility, plant establishment, and growth. Nutrient and pesticide inputs should not be required and may degrade the pollutant processing capability of the bioretention area, as well as contribute pollutant loads to receiving waters. By design, bioretention facilities are located in areas where phosphorous and nitrogen levels are often

- elevated and these should not be limiting nutrients. If in question, have soil analyzed for fertility.
- 5) **Mulch:** Replace mulch annually in bioretention facilities where high trash, sediment load, and heavy metal deposition is likely (e.g., heavy metal contributing areas include industrial and auto dealer/repair parking lots and roads). In residential lots or other areas where metal deposition is not a concern, replace or add mulch as needed to maintain a 2 to 3 inch depth at least once every two years.
 - 6) **Soil:** Soil mixes for bioretention facilities are designed to maintain long-term fertility and pollutant processing capability. Replacing mulch in bioretention facilities where high trash, sediment load, and heavy metal deposition are likely provides an additional level of protection for prolonged performance. Estimates from metal attenuation research suggest that metal accumulation should not present an environmental concern for at least 20 years in bioretention systems. However, the saturated hydraulic conductivity should be assessed at least annually to ensure that the design water quality event is being treated. If in question, have soil analyzed for fertility and pollutant levels.

BIO-2: Planter Box

Planter boxes are bioretention treatment control measures that are completely contained within an impermeable structure with an underdrain (they do not infiltrate). These facilities function as a soil and plant based filtration device that removes pollutants through a variety of physical, biological, and chemical treatment processes. The facilities normally consist of a ponding area, mulch layer, planting soils, plantings, and an underdrain within the planter box. As stormwater passes down through the planting soil, pollutants are filtered, adsorbed, and biodegraded by the soil and plants. Planter boxes are comprised of a variety of materials, usually chosen to be the same material as the adjacent building or sidewalk.

Planter boxes may be placed adjacent to or near buildings, other structures, or sidewalks. Planter boxes can be used directly adjacent to buildings beneath downspouts as long as the boxes are properly lined on the building side and the overflow outlet discharges away from the building to ensure water does not percolate into footings or foundations. They can also be placed further away from buildings by conveying roof runoff in shallow engineered open conveyances, shallow pipes, or other innovative drainage structures.

Planter boxes extending along a building wall

Photo Credit: Geosyntec Consultants

Application

- Areas adjacent to buildings and sidewalks
- Building entrances, courtyards, and walkways

Preventative Maintenance

- Repair small eroded areas
- Remove trash and debris and rake surface soils
- Remove accumulated fine sediments, dead leaves, and trash
- Remove weeds and prune back excess plant growth
- Remove sediment and debris accumulation near inlet and outlet structures

Periodically observe function under wet weather conditions

Limitations

The applicability of stormwater planter boxes is limited by the following site characteristics:

- 1) The tributary area (area draining to the planter box area) should be less than 15,000 ft².
- 2) Groundwater levels should be at least 2 ft lower than the bottom of the planter box.
- 3) Site must have adequate vertical relief between land surface and the stormwater conveyance system to permit connection of the underdrain to the stormwater conveyance system.
- 4) Planter boxes should not be located in areas with excessive shade to avoid poor vegetative growth. For moderately shaded areas, shade tolerant plants should be used.

Design Criteria

Planter boxes should be designed according to the requirements listed in Table 6-19 and outlined in the section below. BMP sizing worksheets are presented in Appendix E.

Table 6-19: Planter Box Design Criteria

Design Parameter	Unit	Design Criteria
Stormwater quality design volume (SQDV)	acre-feet	See Section 2 and Appendix E for calculating SQDV.
Drawdown time of planting soil	hours	12
Maximum ponding depth	inches	12
Minimum soil depth	feet	2; 3 preferred
Stabilized mulch depth	inches	2 to 3
Planting soil composition	-	60 to 70% sand, 30 to 40% compost
Underdrain	-	6 inch minimum diameter; 0.5% minimum slope; slotted, polyvinyl chloride (PVC) pipe (PVC SDR 35 or approved equivalent)
Overflow device	-	Required

Sizing Criteria

See [Sizing Criteria](#) section in the BIO-1: Bioretention with underdrains fact sheet.

Geometry and Size

- 1) Planter boxes areas should be sized to capture and treat the SQDV with a 12 inch maximum ponding depth. The mulch layer should be included as part of the ponding depth.
- 2) Minimum soil depth should be 2 feet, although 3 feet is preferred. *The intention is that a minimum soil depth should provide a beneficial root zone for the chosen plant palette and adequate water storage for the SQDV. A deeper planting soil depth will provide a smaller surface area footprint.*
- 3) Planter boxes should be designed to drain to below the planting soil depth in less than 48 hours. *The intention is that soils must be allowed to dry out periodically in order to restore hydraulic capacity to receive flows from subsequent storms, maintain infiltration rates, prevent long periods of saturation for plant health, maintain adequate soil oxygen levels for healthy soil biota and vegetation, reduce potential for vector breeding, and provide proper soil conditions for biodegradation and retention of pollutants.*
- 4) Any planter box shape configuration is possible as long as other design criteria are met.
- 5) The distance between the downspouts and the overflow outlet should be maximized. *The intention is to increase the opportunity for stormwater retention and filtration.*
- 6) Off-line configurations should be considered to minimize the possibility of scouring and resuspension of previously captured pollutants during large storms.

Structural Materials

- 1) Planter boxes should be constructed out of stone, concrete, brick, recycled plastic, or other permanent materials. Pressure-treated wood or other materials that may leach pollutants (e.g., arsenic, copper, zinc, etc.) should not be allowed.
- 2) The structure should be adequately sealed or a waterproof membrane installed to ensure water only exits the structure via the underdrain.

Flow Entrance and Energy Dissipation

The following types of flow entrance can be used for planter boxes:

- 1) Pipe flow entrance: Piped entrances, such as roof downspouts, should include rock, splash blocks, or other appropriate measures at the entrance to dissipate energy and disperse flows.

- 2) Woody plants (e.g., trees, shrubs, etc.) can restrict or concentrate flows and can be damaged by erosion around the root ball and should not be placed directly in the entrance flow path.

Underdrains

Underdrains are required and should meet the following criteria:

- 1) 6-inch minimum diameter.
- 2) Underdrains should be made of slotted, polyvinyl chloride (PVC) pipe (PVC SDR 35 or approved equivalent). *The intention is that in comparison to round-hole perforated pipe, slotted underdrains provide greater intake capacity, clog resistant drainage, and reduced entrance velocity into the pipe, thereby reducing the chances of solids migration.*
- 3) Slotted pipe should have 2 to 4 rows of slots cut perpendicular to the axis of the pipe or at right angles to the pitch of corrugations. Slots should be 0.04 to 0.1 inch and should have a length of 1 to 1.25 inches. Slots should be longitudinally spaced such that the pipe has a minimum of one square inch opening per lineal foot and should face down.
- 4) Underdrains should be sloped at a minimum of 0.5%.
- 5) Rigid non-perforated observation pipes with a diameter equal to the underdrain diameter should be connected to the underdrain every 100 feet to provide a clean-out port as well as an observation well to monitor dewatering rates. The wells/cleanouts should be connected to the perforated underdrain with the appropriate manufactured connections. The wells/cleanouts should extend 6 inches above the top elevation of the bioretention facility mulch, and should be capped with a lockable screw cap. The ends of underdrain pipes not terminating in an observation well/cleanout should also be capped.
- 6) The following aggregate should be used to provide a gravel blanket and bedding for the underdrain pipe. Place the underdrain on a bed of washed aggregate at a minimum thickness of 6 inches and cover it with the same aggregate to provide a 1 foot minimum depth around the top and sides of the slotted pipe.

Sieve size	Percent Passing
¾ inch	100
¼ inch	30-60
US No. 8	20-50
US No. 50	3-12
US No. 200	0-1

- 7) At the option of the designer/geotechnical engineer, a geotextile fabric may be placed between the planting media and the drain rock. If a geotextile fabric is used, it should

meet a minimum permittivity rate of 75 gal/min/ft², should not impede the infiltration rate of the soil medium, and should meet the following minimum materials requirements.

Geotextile Property	Value	Test Method
Trapezoidal Tear (lbs)	40 (min)	ASTM D4533
Permeability (cm/sec)	0.2 (min)	ASTM D4491
AOS (sieve size)	#60 - #70 (min)	ASTM D4751
Ultraviolet resistance	70% or greater	ASTM D4355

Preferably, aggregate should be used in place of filter fabric to reduce the potential for clogging. This aggregate layer should consist of 2 to 4 inches of washed sand underlain with 2 inches of choking stone (Typically #8 or #89 washed).

- 8) The underdrain should be elevated from the bottom of the bioretention facility by 6 inches within the gravel blanket to create a fluctuating anaerobic/aerobic zone below the drain pipe. *The intention is that denitrification within the anaerobic/anoxic zone is facilitated by microbes using forms of nitrogen (NO₂ and NO₃) instead of oxygen for respiration.*
- 9) The underdrain must drain freely to an acceptable discharge point. The underdrain can be connected to a downstream open conveyance (vegetated swale), to another bioretention cell as part of a connected treatment system, to a storm drain, daylight to a vegetated dispersion area using an effective flow dispersion device, or to a storage facility for rainwater harvesting.

Overflow

An overflow device is required to be set at 2 inches below the top of the planter and no more than 12 inches above the soil surface. The most common option is a vertical riser, described below.

Vertical riser

- 1) A vertical PVC pipe (SDR 35) should be connected to the underdrain.
- 2) The overflow riser(s) should be 6 inches or greater in diameter, so it can be cleaned without damage to the pipe. The vertical pipe will provide access to cleaning the underdrains.
- 3) The inlet to the riser should be a maximum of 12 inches above the planting soil, and be capped with a spider cap. Spider caps should be screwed in or glued (i.e., not removable).

Hydraulic Restriction Layers

A waterproof barrier should be provided to restrict moisture away from foundations. Geomembrane liners should have a minimum thickness of 30 mils. Equivalent waterproofing measures may be used.

Planting/Storage Media

- 1) The planting media placed in the cell should achieve a long-term, in-place infiltration rate of at least 1 inch per hour. Higher infiltration rates are permissible. If the design long-term, in-place infiltration rate of the soil exceeds 12 inches per hour, documentation should be provided to demonstrate that the media will adequately address pollutants of concern at a higher flowrate. Planter box soil shall also support vigorous plant growth.
- 2) Planting media should consist of 60 to 80% fine sand and 20 to 40% compost.
- 3) Sand should be free of wood, waste, coating such as clay, stone dust, carbonate, etc., or any other deleterious material. All aggregate passing the No. 200 sieve size should be non-plastic. Sand for the planter box should be analyzed by an accredited lab using #200, #100, #40, #30, #16, #8, #4, and 3/8 sieves (ASTM D 422 or as approved by the local permitting authority) and meet the following gradation (Note: all sands complying with ASTM C33 for fine aggregate comply with the gradation requirements below):

Sieve Size (ASTM D422)	% Passing (by weight)	
	Minimum	Maximum
3/8 inch	100	100
#4	90	100
#8	70	100
#16	40	95
#30	15	70
#40	5	55
#100	0	15
#200	0	5

Note: the gradation of the sand component of the media is believed to be a major factor in the hydraulic conductivity of the media mix. If the desired hydraulic conductivity of the media cannot be achieved within the specified proportions of sand and compost (#2), then it may be necessary to utilize sand at the coarser end of the range specified in above (“minimum” column).

- 4) Compost should be a well decomposed, stable, weed free organic matter source derived from waste materials including yard debris, wood wastes, or other organic materials not including manure or biosolids meeting standards developed by the US Composting Council (USCC). The product shall be certified through the USCC Seal

of Testing Assurance (STA) Program (a compost testing and information disclosure program). Compost quality should be verified via a lab analysis to be:

- Feedstock materials shall be specified and include one or more of the following: landscape/yard trimmings, grass clippings, food scraps, and agricultural crop residues.
- Organic matter: 35-75% dry weight basis.
- Carbon and Nitrogen Ratio: 15:1 < C:N < 25:1
- Maturity/Stability: shall have dark brown color and a soil-like odor. Compost exhibiting a sour or putrid smell, containing recognizable grass or leaves, or is hot (120 F) upon delivery or rewetting is not acceptable.
- Toxicity: any one of the following measures is sufficient to indicate non-toxicity:
 - $NH_4:NH_3 < 3$
 - Ammonium < 500 ppm, dry weight basis
 - Seed Germination > 80% of control
 - Plant trials > 80% of control
 - Solvita® > 5 index value
- Nutrient content:
 - Total Nitrogen content 0.9% or above preferred
 - Total Boron should be <80 ppm, soluble boron < 2.5 ppm
- Salinity: < 6.0 mmhos/cm
- pH between 6.5 and 8 (may vary with plant palette)

Compost for planter box should be analyzed by an accredited lab using #200, 1/4 inch, 1/2 inch, and 1 inch sieves (ASTM D 422 or as approved by the local permitting authority) and meet the following gradation:

Sieve Size (ASTM D422)	% Passing (by weight)	
	Minimum	Maximum
1 inch	99	100
1/2 inch	90	100
1/4 inch	40	90
#200	2	10

Tests should be sufficiently recent to represent the actual material that is anticipated to be delivered to the site. If processes or sources used by the supplier have changed significantly since the most recent testing, new tests should be requested.

Note: the gradation of compost used in planter box media is believed to play an important role in the saturated hydraulic conductivity of the media. To achieve a higher saturated hydraulic conductivity, it may be necessary to utilize compost at the coarser end of this range (“minimum” column). The percent passing the #200 sieve (fines) is believed to be the most important factor in hydraulic conductivity.

In addition, a coarser compost mix provides more heterogeneity of the planter box media, which is believed to be advantageous for more rapid development of soil structure needed to support health biological processes. This may be an advantage for plant establishment with lower nutrient and water input.

- 5) The planter box should be covered with 2 to 4 inches (average 3 inches) of mulch at the start and an additional placement of 1 to 2 inches of mulch should be added annually. *The intention is that to help sustain the nutrient levels, suppress weeds, retain moisture, and maintain infiltration capacity.*

Plants

- 1) Plant materials should be tolerant of summer drought, ponding fluctuations, and saturated soil conditions for 48 to 96 hours.
- 2) It is recommended that a minimum of three types of tree, shrubs, and/or herbaceous groundcover species be incorporated to protect against facility failure due to disease and insect infestations of a single species.
- 3) Native plant species and/or hardy cultivars that are not invasive and do not require chemical inputs should be used to the maximum extent practicable.
- 4) Plants should be selected carefully to minimize maintenance and function properly.

Operations and Maintenance

Planter boxes require annual plant, soil, and mulch layer maintenance to ensure optimum infiltration, storage, and pollutant removal capabilities. In general, planter box maintenance requirements are typical of landscape care procedures and include:

- 1) Watering: Plants should be selected to be drought-tolerant and do not require watering after establishment (2 to 3 years). Watering may be required during prolonged dry periods after plants are established.
- 2) Erosion control: Inspect flow entrances, ponding area, and surface overflow areas periodically, and replace soil, plant material, and/or mulch layer in areas if erosion has occurred (see Appendix I for an inspection and maintenance checklist). Properly designed facilities with appropriate flow velocities should not have erosion problems

- except perhaps in extreme events. If erosion problems occur, the following should be reassessed: (1) flow velocities and gradients within the cell, and (2) flow dissipation and erosion protection strategies in the flow entrance. If sediment is deposited in the planter box, immediately determine the source within the contributing area, stabilize, and remove excess surface deposits.
- 3) Plant material: Depending on aesthetic requirements, occasional pruning and removing of dead plant material may be necessary. Replace all dead plants and if specific plants have a high mortality rate, assess the cause and, if necessary, replace with more appropriate species. Periodic weeding is necessary until plants are established. The weeding schedule should become less frequent if the appropriate plant species and planting density have been used and, as a result, undesirable plants have been excluded.
 - 4) Nutrients and pesticides: The soil mix and plants are selected for optimum fertility, plant establishment, and growth. Nutrient and pesticide inputs should not be required and may degrade the pollutant processing capability of the planter box area, as well as contribute pollutant loads to receiving waters. By design, planter boxes are located in areas where phosphorous and nitrogen levels are often elevated and these should not be limiting nutrients. If in question, have soil analyzed for fertility.
 - 5) Mulch: Replace mulch annually in planter boxes where high trash, sediment load, and heavy metal deposition is likely (e.g., heavy metal contributing areas include industrial, auto dealer/repair, parking lots, and roads). In residential lots or other areas where metal deposition is not a concern, replace or add mulch as needed to maintain a 2 to 3 inch depth at least once every two years.
 - 6) Soil: Soil mixes for planter boxes are designed to maintain long-term fertility and pollutant processing capability. Replacing mulch in planter boxes where high trash, sediment load, and heavy metal deposition are likely provides an additional level of protection for prolonged performance. Estimates from metal attenuation research suggest that metal accumulation should not present an environmental concern for at least 20 years in planter boxes. However, the saturated hydraulic conductivity should be assessed at least annually to ensure that the design water quality event is being treated. If in question, have soil analyzed for fertility and pollutant levels.

BIO-3: Vegetated Swale

Vegetated swales are open, shallow channels with low-lying vegetation covering the side slopes and bottom that collect and slowly convey runoff to downstream discharge points. Vegetated swales provide pollutant removal through settling and filtration in the vegetation (usually grasses) lining the channels, provide the opportunity for stormwater volume reduction through infiltration and evapotranspiration, reduce the flow velocity, and conveying stormwater runoff. An effective vegetated swale achieves uniform sheet flow through a densely vegetated area for a period of several minutes. The vegetation in the swale can vary depending on its location and is the choice of the designer, depending on the design criteria outlined in this section.

Vegetated swale captures flow from a residential street

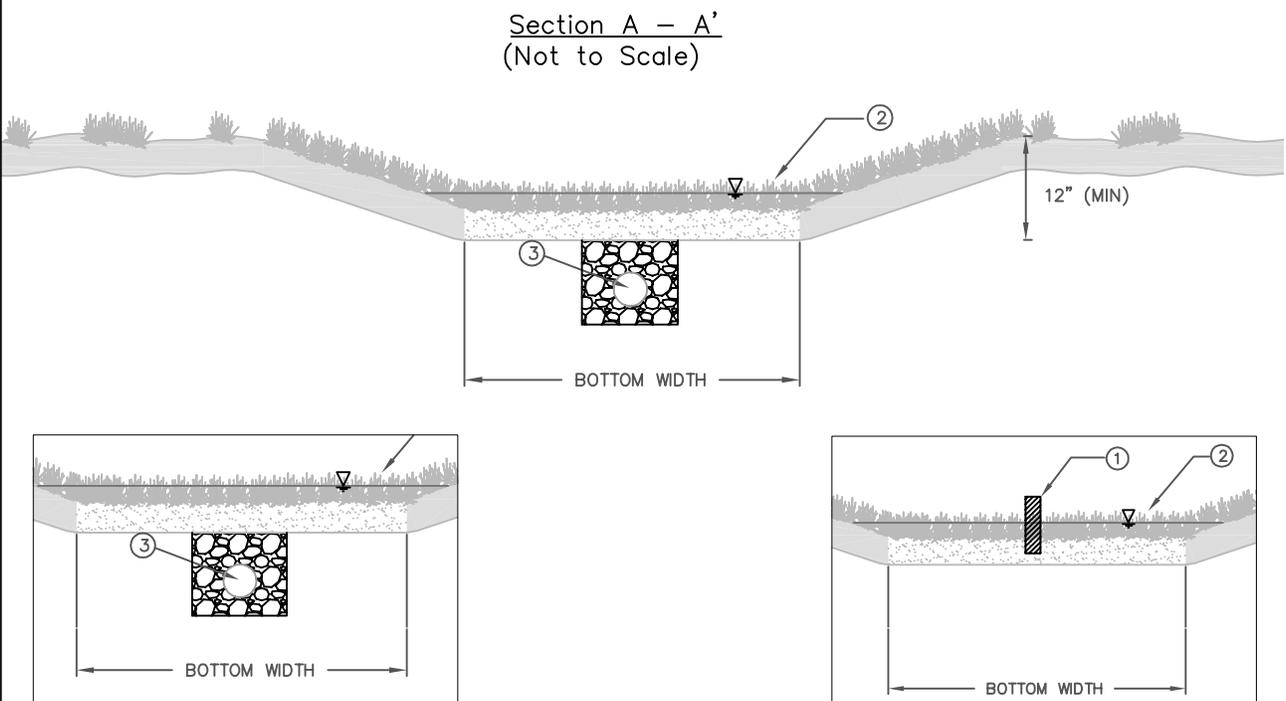

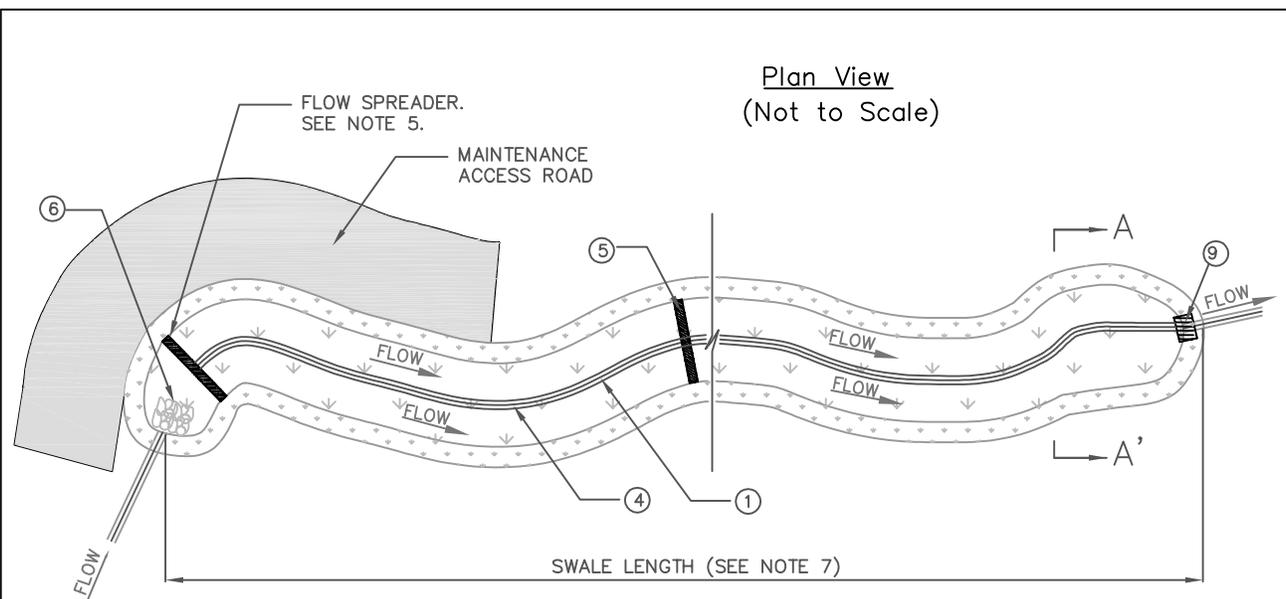

Photo Credit: Geosyntec Consultants

Application

- Open areas adjacent to parking lots
- Open spaces adjacent to athletic fields
- Roadway medians and shoulders

Preventative Maintenance

- Remove excess sediment, trash, and debris
- Clean and reset flow spreaders
- Mow regularly
- Remove sediment and debris build-up near inlets and outlets
- Repair minor erosion and scouring

NOTES:

- ① SWALE DIVIDER REQUIRED FOR BOTTOM WIDTHS > 10'. MINIMUM REQUIRED BOTTOM WIDTH IS 2' EXCLUDING WIDTH OF LOW FLOW CHANNEL. MAXIMUM BOTTOM WIDTH WITH DIVIDER IS 16'.
- ② DEPTH OF FLOW FOR WATER QUALITY TREATMENT MUST NOT EXCEED TWO-THIRDS OF VEGETATION HEIGHT OR NOT GREATER THAN 2" FOR FREQUENTLY MOWED TURF.
- ③ IF AN UNDERDRAIN IS REQUIRED, IT MUST CONSIST OF AN AT LEAST 6" DIAMETER PERFORATED PIPE IN COARSE AGGREGATE BED CONNECTED TO STORM DRAIN. GRAVEL BED MUST EXTEND 6" BELOW AND 12" TO THE SIDE AND TOP OF THE PIPE.
- ④ IF NO UNDERDRAIN, LOW FLOW DRAIN SHALL EXTEND ENTIRE LENGTH OF SWALE AND SHALL HAVE A DEPTH OF 6" MINIMUM AND WIDTH NO MORE THAN 5% SWALE BOTTOM WIDTH. ANCHORED PLATE FLOW SPREADER IF USED, SHALL HAVE V-NOTCHES (MAX TOP WIDTH = 5% OF SWALE WIDTH) OR HOLES TO ALLOW PREFERENTIAL EXIT OF LOW FLOWS.
- ⑤ INSTALL CHECK DAMS OR GRADE CONTROL STRUCTURES FOR SLOPES > 2% AT 50' MAXIMUM SPACING TO ACHIEVE A MAXIMUM EFFECTIVE LONGITUDINAL SLOPE OF 2%. FLOW SPREADERS SHALL BE PROVIDED AT INLET AND AT THE BASE OF EACH CHECK DAM.
- ⑥ INSTALL ENERGY DISSIPATOR AT THE INLET OF VEGETATED SWALE.
- ⑦ SWALE LENGTH SHALL LENGTH REQUIRED TO PROVIDE 7 MINUTES RESIDENCE TIME.
- ⑧ INSTALL APPROPRIATE OUTLET STRUCTURE. ACCOMMODATE LOW FLOW CHANNEL AND/OR UNDERDRAIN (IF PRESENT).
- ⑨ AMEND SOILS WITH 2" OF COMPOST TILLED INTO 6" OF NATIVE SOIL UNLESS NATIVE SOIL ORGANIC CONTENT > 10%.

<p>Figure 6-12: Vegetated Swale</p>	

Limitations

- 1) Compatibility with flood control - swales should not interfere with flood control functions of existing conveyance and detention structures.
- 2) Vegetation - select vegetation appropriately based on irrigation requirements and exposure (shady versus sunny areas). A thick vegetative cover is needed for vegetated swales to function properly. Native and drought tolerant plants are recommended.
- 3) Drainage area - each vegetated swale can treat a relatively small drainage area. Large areas should be divided and treated using multiple swales.

Design Criteria

Vegetated swales should be designed according to the requirements listed in Table 6-20 and outlined in the section below. BMP sizing worksheets are presented in Appendix E.

Table 6-20: Vegetated Swale Filter Design Criteria

Design Parameter	Unit	Design Criteria
Stormwater quality design flow rate (SQDF)	cfs	See Section 2 and Appendix E for calculating SQDF.
Swale Geometry	-	Trapezoidal
Minimum bottom width	feet	2
Maximum bottom width	feet	10; if greater than 10 must use swale dividers; with dividers, max is 16
Minimum length	feet	sufficient length to provide minimum contact time
Minimum slope in flow direction	%	0.2 (provide underdrains for slopes less < 0.5%)
Maximum slope in flow direction	%	2.0 (provide grade-control checks for slopes > 2.0)
Maximum flow velocity	ft/sec	1.0 (water quality treatment); 3.0 (flood conveyance)
Maximum depth of flow for water quality treatment	inches	3 to 5 (1 inch below top of grass)
Minimum residence (contact) time	minutes	7 (provide sufficient length to yield minimum residence time)
Vegetation type	--	Varies (see vegetation section below); Native and drought tolerant plants are recommended
Vegetation height	inches	4 to 6 (trim or mow to maintain height)

Sizing Criteria

The flow capacity of a vegetated swale is a function of the longitudinal slope (parallel to flow), the resistance to flow (i.e. Manning's roughness), and the cross sectional area. The cross section is normally approximately trapezoidal and the area is a function of the bottom width and side slopes. The flow capacity of vegetated swales should be such that the SQDF will not exceed a flow depth of 2/3 the height of the vegetation within the swale or 4 inches at the SQDF. Once design criteria have been selected, the resulting flow depth for the SQDF is checked. If the depth restriction is exceeded, swale parameters (e.g. longitudinal slope, width) are adjusted to reduce the flow depth.

Procedures for sizing vegetated swales are summarized below. A vegetated swale sizing worksheet and example are also provided.

Step 1: Select design flows

The swale sizing is based on the SQDF (see [Section 2](#) and Appendix E).

Step 2: Calculate swale bottom width

The swale bottom width (b) is calculated based on Manning's equation for open-channel flow. This equation can be used to calculate discharges (Q) as follows:

$$Q = \frac{1.49AR^{0.67}S^{0.5}}{n} \quad \text{(Equation 6-27)}$$

Where:

Q	=	flow rate (cfs)
n	=	Manning's roughness coefficient (unitless)
A	=	cross-sectional area of flow (ft ²)
R	=	hydraulic radius (ft) = area divided by wetted perimeter
S	=	longitudinal slope (ft/ft)

For shallow flow depths in swales, channel side slopes are ignored in the calculation of bottom width. Use the following equation (a simplified form of Manning's formula) to estimate the swale bottom width (b):

$$b = \frac{SQDF * n_{wq}}{1.49y^{0.67} s^{0.5}} \quad \text{(Equation 6-28)}$$

Where:

b	=	bottom width of swale (ft)
---	---	----------------------------

$SQDF$	=	stormwater quality design flow (cfs)
n_{wq}	=	Manning's roughness coefficient for shallow flow conditions = 0.2 (unitless)
y	=	design flow depth (ft)
s	=	longitudinal slope (along direction of flow) (ft/ft)

Proceed to Step 3 if the bottom width is calculated to be between 2 and 10 feet. A minimum 2-foot bottom width is required. Therefore, if the calculated bottom width is less than 2 feet, increase the width to 2 feet and recalculate the design flow depth y using the Equation 6-18, where $SQDF$, n_{wq} , and s are the same values as used above, but $b = 2$ feet.

The maximum allowable bottom width is 10 feet. Therefore, if the calculated bottom width exceeds 10 feet, then one of the following steps is necessary to reduce the design bottom width:

- 1) Increase the longitudinal slope (s) to a maximum of 2 feet in 100 feet (0.02 feet per foot).
- 2) Increase the design flow depth (y) to a maximum of 4 inches.
- 3) Place a divider lengthwise along the swale bottom (Figure 6-11) at least three-quarters of the swale length (beginning at the inlet), without compromising the design flow depth and swale lateral slope requirements. The swale width can be increased to an absolute maximum of 16 feet if a divider is provided.

Step 3: Determine design flow velocity

To calculate the design flow velocity (V_{wq}) through the swale, use the flow continuity equation:

$$V_{wq} = SQDF/A_{wq} \quad \text{(Equation 6-29)}$$

Where:

V_{wq}	=	design flow velocity (fps)
$SQDF$	=	stormwater quality design flow (cfs)
A_{wq}	=	$by + Zy^2$ = cross-sectional area (ft ²) of flow at design depth, where Z = side slope length per unit height (e.g., $Z = 3$ if side slopes are 3H:1V)

If the design flow velocity exceeds 1 foot per second, go back to Step 2 and modify one or more of the design parameters (longitudinal slope, bottom width, or flow depth) to

reduce the design flow velocity to 1 foot per second or less. If the design flow velocity is calculated to be less than 1 foot per second, proceed to Step 4. *Note: It is desirable to have the design velocity as low as possible, both to improve treatment effectiveness and to reduce swale length requirements.*

Step 4: Calculate swale length

Use the following equation to determine the necessary swale length (L) to achieve a hydraulic residence time of at least 7 minutes:

$$L = 60t_{hr}V_{wq} \quad \text{(Equation 6-30)}$$

Where:

L	=	minimum allowable swale length (ft)
t_{hr}	=	hydraulic residence time (min)
V_{wq}	=	design flow velocity (fps), calculated by Equation 6-19

If there is adequate space on the site to accommodate a larger swale, consider using a greater length to increase the hydraulic residence time and improve the swale's pollutant removal capability. If the calculated length is too long for the site, or if it would cause layout problems, such as encroachment into shaded areas, proceed to Step 5 to further modify the layout. If the swale length can be accommodated on the site (meandering may help), proceed to Step 6.

Step 5: Adjust swale layout to fit on site

If the swale length calculated in Step 4 is too long for the site, the length can be reduced (to a minimum of 100 feet) by increasing the bottom width up to a maximum of 16 feet, as long as the 10 minute retention time is retained. However, the length cannot be increased in order to reduce the bottom width because Manning's depth-velocity-flow rate relationships would not be preserved. If the bottom width is increased to greater than 10 feet, a low flow dividing berm is needed to split the swale cross section in half to prevent channelization.

Length can be adjusted by calculating the top area of the swale and providing an equivalent top area with the adjusted dimensions.

- 1) Calculate the swale treatment top area (A_{top}), based on the swale length calculated in Step 4:

$$A_{top} = (b_i + b_{slope})L_i \quad \text{(Equation 6-31)}$$

Where:

- A_{top} = top area (ft²) at the design treatment depth
- b_i = bottom width (ft), calculated in Step 2 using Equation 6-18
- b_{slope} = the additional top width (ft) above the side slope for the design water depth (for 3:1 side slopes and a 4-inch water depth, $b_{slope} = 2$ feet)
- L_i = initial length (ft) calculated in Step 4 using Equation 6-30

- 2) Use the swale top area and a reduced swale length (L_f) to increase the bottom width, using the following equation:

$$L_f = A_{top} / (b_f + b_{slope}) \tag{Equation 6-32}$$

Where:

- L_f = reduced swale length (ft)
- b_f = increased bottom width (ft)

- 3) Recalculate V_{wq} according to Step 3 using the revised cross-sectional area A_{wq} based on the increased bottom width (b_f). Revise the design as necessary if the design flow velocity exceeds 1 foot per second.
- 4) Recalculate to ensure that the 10 minute retention time is retained.

Step 6: Provide conveyance capacity for flows higher than SQDF

Vegetated swales may be designed as flow-through channels that convey flows higher than the SQDF, or they may be designed to incorporate a high-flow bypass upstream of the swale inlet. A high-flow bypass usually results in a smaller swale size. If a high-flow bypass is provided, this step is not needed. If no high-flow bypass is provided, proceed with the procedure below. A flow splitter structure design is described in Appendix F.

- 1) Check the swale size to determine whether the swale can convey the flood control design storm peak flow (Refer to Ventura County Hydrology Manual, revised 2006).
- 2) The peak flow velocity of the flood control design storm (see Ventura County Hydrology Manual revised 2006) should be less than 3.0 feet per second. If this velocity exceeds 3.0 feet per second, return to Step 2 and increase the bottom width or flatten the longitudinal slope as necessary to reduce the flood control design storm peak flow velocity to 3.0 feet per second or less. If the longitudinal slope is flattened, the swale bottom width must be recalculated (Step 2) and must meet all design criteria.

Geometry and Size

- 1) In general, a trapezoidal channel shape should be assumed for sizing calculations above, but a more naturalistic channel cross-section is preferred.
- 2) Swales designed for water quality treatment purposes only are usually fairly shallow, generally less than 1 ft. Therefore, a side slope of 2:1 (H:V) can be used and is acceptable.
- 3) Swales shall be greater than 100 feet in length. The vegetated swale can be shorter than 100 feet if it is used for pretreatment only (i.e., prior to infiltration). Length can be increased by meandering the swale.
- 4) The minimum swale bottom width shall be 2 feet to allow for ease of mowing.
- 5) The maximum swale bottom width shall be limited to 10 feet, unless a swale divider is provided, then the maximum bottom width can be a maximum of 16 feet wide. The swale width is calculated without the swale diving berm. *The intention is that experience shows that when the width exceeds about 10 feet, it is difficult to keep the water from concentrating in low flow channels. It is also difficult to construct the bottom level without sloping to one side. Vegetated swales are best constructed by leveling the bottom after excavating. A single-width pass with a front-end loader produces a better result than a multiple-width pass.*
- 6) Swales that are required to convey flood flow as well as the SQDF should be sized to convey the flood control design storm and include a provision of freeboard as required by the local approval authority.
- 7) Gradual meandering bends in the swale are desirable for aesthetic purposes and to promote slower flow.

Bottom Slope

- 1) The longitudinal slope (along the direction of flow) should be between 1% and 6%.
- 2) If longitudinal slopes are less than 1.5% and the soils are poorly drained (e.g., silts and clays), then underdrains should be provided. A soils report to verify soils properties should be provided for swales less than 1.5%.
- 3) If longitudinal slope exceeds 2%, check dams with vertical drops of 12 inches or less should be provided to achieve a bottom slope of 2% or less between the drop structures.
- 4) The lateral (horizontal) slope at the bottom of the swale should be zero (flat) to discourage channeling.

Water Depth and Dry Weather Flow Drain

- 1) Water depth should not exceed 4 inches (or 2/3 of the expected vegetation height), except for frequently mowed turf swales, in which the depth should not exceed 2 inches.
- 2) The swale length must provide a minimum hydraulic residence time of 7 minutes.
- 3) A low flow drain should be provided if the potential for dry weather flows exists. The low flow drain should extend the entire length of the swale. The drain should have a minimum depth of 6 inches, and a width no more than 5% of the calculated swale bottom width. The width of the drain should be in addition to the required bottom width. The flow spreader at the swale inlet should have v-notches (maximum top width = 5% of swale width) or holes to allow preferential exit of low flows into the drain, if applicable. If an underdrain or gravel drainage layer is installed as discussed below, the low flow drain should be omitted.

Swale Inflow and Design Capacity

- 1) Whenever possible, inflow should be directed towards the upstream end of the swale and should, at a minimum, occur evenly over the length of the swale. Swale inflow design should provide for positive drainage into the swale to function on the long-term with minimal maintenance.
- 2) On-line vegetated swales should be designed to convey flow rates up to the post-development peak stormwater runoff discharge rate (flow rate) for the 100-yr 24-hour storm event, with appropriate freeboard (see Ventura County Hydrology Manual, revised 2006).
- 3) Off-line vegetated swales should be designed to convey the flow-based SQDF by using a flow diversion structure (e.g., flow splitter) which diverts the SQDF to the off-line vegetated swale designed to handle SQDF. Freeboard for off-line swales is not required, but should be provided if space is available. Flow splitter design specifications are described in Appendix F.

Energy Dissipation

- 1) Vegetated swales may be designed either on-line or off-line. If the facility is on-line, velocities should be maintained below the maximum design flow velocity of 3 feet per second to prevent scour and resuspension of deposited sediments.
- 2) The maximum flow velocity under the stormwater quality design flow rate should not exceed 1.0 foot per second. *The intention is that this maximum SQDV promotes settling and keeps vegetation upright.*
- 3) This velocity limitation combined with a maximum depth of 4 inches and bottom width of 10 feet results in a recommended maximum flow capacity of about 3.3 cfs,

- after accounting for the side slopes. The contributory drainage area to each swale is limited so as not to exceed this recommended maximum flow capacity.
- 4) The maximum flow velocity during the 100-yr 24-hr storm event should not exceed 3.0 foot per second. This can be accomplished by:
 - a. Splitting roadside swales near high points in the road so that flows drain in opposite directions, mimicking flow patterns on the road surface.
 - b. Limiting tributary areas to long swales by diverting flows throughout the length of the swale at regular intervals, to the downstream stormwater conveyance system.
 - 5) A flow spreader (see “Flow Spreaders” below) should be used at the inlet so that the entrance velocity is quickly dissipated and the flow is uniformly distributed across the whole swale. Energy dissipation controls should be constructed of sound materials such as stones, concrete, or proprietary devices that are rated to withstand the energy of the influent flows.
 - 6) If check dams are used to reduce the longitudinal slope, a flow spreader should be provided at the toe of each vertical drop, with specifications described below.
 - 7) If flow is to be introduced through curb cuts, place pavement approximately one inch above the elevation of the vegetated areas. Curb cuts should be at least 12 inches wide to prevent clogging.

Flow Spreaders

- 1) An anchored plate flow spreader or similar device should be provided at the inlet to the swale. Equivalent methods for spreading flows evenly throughout the width of the swale are acceptable.
- 2) The top surface of the flow spreader plate should be level, projecting a minimum of 2 inches above the ground surface of the water quality facility, or v-notched with notches 6 to 10 inches on center and 1 to 4 inches deep (use shallower notches with closer spacing).
- 3) A flow spreader plate should extend horizontally beyond the bottom width of the facility to prevent water from eroding the side slope. The plate should have a row of horizontal perforations at its base to prevent ponding for long durations. The horizontal extent should be such that the bank is protected for all flows up to the 100-yr 24-hr storm event (on-line swales) or the maximum flow that will enter the water quality facility (off-line swales).
- 4) Flow spreader plates should be securely fixed in place.
- 5) Flow spreader plates may be made of either concrete, stainless steel, or other durable material.

- 6) Anchor posts should be 4-inch square concrete, tubular stainless steel, or other material resistant to decay.

Check Dams

If check dams are required, they can be designed using a number of different materials, including riprap, earthen berms, or removal stop logs. Where vegetated swales parallel urban streets, the check dam can double as a crossing walk so that pedestrians have a pathway from the parked car to the building.

Check dams must be placed as to achieve the desired slope (1 to 6%) at a maximum of 50 feet apart. Check dams should be no higher than 12 inches. If riprap is used, the material should consist of well-graded stone consisting of a mixture of rock sizes. The following is an example of an acceptable gradation:

Particle Size	% Passing
24 inch	100
15 inch	75
9 inch	50
4 inch	10

Underdrains

If underdrains (not to be confused with a dry weather flow drain) are required, then they should meet the following criteria:

- 1) Underdrains should be made of slotted, polyvinyl chloride (PVC) pipe (PVC SDR 35 or approved equivalent). *The intention is that in comparison to round-hole perforated pipe, slotted underdrains provide greater intake capacity, clog resistant drainage, and reduced entrance velocity into the pipe, thereby reducing the chances of solids migration.*
- 2) Slotted pipe should have 2 to 4 rows of slots cut perpendicular to the axis of the pipe or at right angles to the pitch of corrugations. Slots should be 0.04 to 0.1 inch and should have a length of 1 to 1.25 inches. Slots should be longitudinally spaced such that the pipe has a minimum of one square inch of opening per linear foot of pipe.
- 3) Underdrains should be sloped at a minimum of 0.5%.
- 4) The underdrain pipe should be 6 inches or greater in diameter, so it can be cleaned without damage to the pipe. Clean-out risers with diameters equal to the underdrain pipe should be placed at the terminal ends of the underdrain and can be incorporated into the flow spreader and outlet structure to minimize maintenance obstacles in the swale. Intermediate clean-out risers may also be placed in the check dams or grade control structures. The cleanout risers should be capped with a lockable screw cap.

- 5) The underdrain should be placed parallel to the swale bottom and backfilled and underbedded with six inches of drain rock. The following coarse aggregate should be used to provide a gravel blanket and bedding for the underdrain pipe to provide a 1 foot minimum depth around the top and sides of the slotted pipe.

Sieve size	Percent Passing
¾ inch	100
¼ inch	30-60
US No. 8	20-50
US No. 50	3-12
US No. 200	0-1

- 6) At the option of the designer/geotechnical engineer, the drain rock may be wrapped in a geotextile fabric meeting the following minimum materials requirements. If a geotextile fabric is used, it should pass 75 gal/min/ft², should not impede the infiltration rate of the soil medium, and should meet the following minimum materials requirements.

Geotextile Property	Value	Test Method
Trapezoidal Tear (lbs)	40 (min)	ASTM D4533
Permeability (cm/sec)	0.2 (min)	ASTM D4491
AOS (sieve size)	#60 - #70 (min)	ASTM D4751
Ultraviolet resistance	70% or greater	ASTM D4355

Preferably, aggregate should be used in place of geotextile fabric to reduce the potential for clogging. This aggregate layer should consist of 2 to 4 inches of washed sand underlain with 2 inches of choking stone (Typically #8 or #89 washed).

- 7) The underdrain should drain freely to an acceptable discharge point. The underdrain can be connected to a downstream open conveyance (vegetated swale), to another bioretention cell as part of a connected treatment system, daylight to a vegetated dispersion area using an effective flow dispersion device, stored for rainwater harvesting, or to a storm drain.

Gravel Drainage Layer

To increase volume reduction and if soil conditions allow (infiltration rate > 0.5 in/hr), omit the low flow drain or underdrain and install an appropriately sized gravel drainage layer (typically a washed 57 stone) beneath the swale to achieve desired volume reduction goals. Where slopes are greater than 1%, the gravel drainage layer should be installed in combination with check dams (e.g., drop structures) to slow the flow in the swale and allow for infiltration into the gravel drainage layer and then into the subsurface. The base of the drainage layer should have zero slope. The drawdown time in the gravel drainage layer should not exceed 72 hours. The soil and gravel layers should

be separated with a geotextile filter fabric or a thin, 2 to 4 inch layer of pure sand and a thin layer (nominally two inches) of choking stone (such as #8). Sizing of the gravel drainage layer is based on volume reduction requirements.

Swale Divider

- 1) If a swale divider is used, the divider should be constructed of a firm material that will resist weathering and not erode, such as concrete, plastic, or compacted soil seeded with grass. Treated timber should not be used. Selection of divider material should take into account maintenance activities, such as mowing.
- 2) The divider should have a minimum height of 1 inch greater than the stormwater quality design water depth.
- 3) Earthen berms should be no steeper than 2H:1V.
- 4) Material other than earth should be embedded to a depth sufficient to be stable.

Soils

Swale soils should be amended with 2 inches of compost, unless the organic content is already greater than 10%. The compost should be mixed into the native soils to a depth of 6 inches to prevent soil layering and washout of compost. The compost will contain no sawdust, green or under-composted material, or any other toxic or harmful substance. It should contain no un-sterilized manure, which can lead to high levels of pathogen indicators (coliform bacteria) in the runoff.

Vegetation

Swales must be vegetated in order to provide adequate treatment of runoff via filtration. Vegetation, when chosen and maintained appropriately, also improves the aesthetics of a site. It is important to maximize water contact with vegetation and the soil surface.

- 1) The swale area should be appropriately vegetated with a mix of erosion-resistant plant species that effectively bind the soil. A diverse selection of low growing plants that thrive under the specific site, climatic, and watering conditions should be specified. A mixture of dry-area and wet-area grass species that can continue to grow through silt deposits is most effective. Native or adapted grasses are preferred because they generally require less fertilizer, limited maintenance, and are more drought-resistant than exotic plants. When appropriate, swales that are integrated within a project may use turf or other more intensive landscaping, while swales that are located on the project perimeter, within a park, or close to an open space area are encouraged to be planted with a more naturalistic plant palette.
- 2) Trees or shrubs may be used in the landscape as long as they do not over-shade the turf.

- 3) Above the design treatment elevation, a typical lawn mix or landscape plants can be used provided they do not shade the swale vegetation.
- 4) Irrigation is required if the seed is planted in the spring or summer. Use of a permanent irrigation system may help provide maximal water quality performance. Drought-tolerant grasses should be specified to minimize irrigation requirements.
- 5) Vegetative cover should be at least 4 inches in height, ideally 6 inches. Swale water depth should ideally be $2/3$ of the height of the shortest plant species.
- 6) Locate the swale in an area without excessive shade to avoid poor vegetative growth. For moderately shaded areas, shade tolerant plants should be used.
- 7) Locate the swale away from large trees that may drop excessive leaves or needles, which may smother the grass or impede the flow through the swale. Landscape planter beds should be designed and located so that soil does not erode from the beds and enter a nearby swale.

Maintenance Access

- 1) Access to the swale inlet and outlet should be safely provided, with ample room for maintenance and operational activities.

Operations and Maintenance

- 1) Inspect vegetated swales for erosion or damage to vegetation after every storm greater than 0.75 inches for on-line swales and at least twice annually for off-line swales, preferably at the end of the wet season to schedule summer maintenance and in the fall to ensure readiness for winter. Additional inspection after periods of heavy runoff is recommended. Each swale should be checked for debris and litter and areas of sediment accumulation (see Appendix I for a vegetated swale inspection and maintenance checklist).
- 2) Swale inlets (curb cuts or pipes) should maintain a calm flow of water entering the swale. Remove sediment as needed at the inlet, if vegetation growth is inhibited in greater than 10% of the swale or if the sediment is blocking even distribution and entry of the water. Following sediment removal activities, replanting and/or reseeding of vegetation may be required for reestablishment.
- 3) Flow spreaders should provide even dispersion of flows across the swale. Sediments and debris should be removed from the flow spreader if blocking flows. Splash pads should be repaired if needed to prevent erosion. Spreader level should be checked and leveled if necessary.
- 4) Side slopes should be maintained to prevent erosion that introduces sediment into the swale. Slopes should be stabilized and planted using appropriate erosion control measures when native soil is exposed or erosion channels are formed.

- 5) Swales should drain within 48 hours of the end of a storm. Till the swale if compaction or clogging occurs and revegetate. If a perforated underdrain pipe is present, it should be cleaned if necessary.
- 6) Vegetation should be healthy and dense enough to provide filtering, while protecting underlying soils from erosion:
 - Mulch should be replenished as needed to ensure survival of vegetation.
 - Vegetation, large shrubs or trees that interfere with landscape swale operation should be pruned.
 - Fallen leaves and debris from deciduous plant foliage should be removed.
 - Grassy swales should be mowed to 4 to 6 inches height. Grass clippings should be removed.
 - Invasive vegetation, such as Alligatorweed (*Alternanthera philoxeroides*), Halogeton (*Halogeton glomeratus*), Spotted Knapweed (*Centaurea maculosa*), Giant Reed (*Arundo donax*), Castor Bean (*Ricinus communis*), Perennial Pepperweed (*Lepidium latifolium*), and Yellow Starthistle (*Centaurea solstitialis*) should be removed and replaced with non-invasive species. Invasive species should never contribute more than 10% of the vegetated area. For more information on invasive weeds, including biology and control of listed weeds, look at the [encycloweedia](#) located at the California Department of Food and Agriculture website or the California Invasive Plant Council website at www.cal-ipc.org.
 - Dead vegetation should be removed if greater than 10% of area coverage or when swale function is impaired. Vegetation should be replaced and established before the wet season to maintain cover density and control erosion where soils are exposed.
- 7) Check dams (if present) should control and distribute flow across the swale. Causes for altered water flow and/or channelization should be identified and obstructions cleared. Check dams and swale should be repaired if damaged.
- 8) The vegetated swale should be well maintained. Trash and debris, sediment, visual contamination (e.g., oils), noxious or nuisance weeds, should all be removed.

BIO-4: Vegetated Filter Strip

Filter strips are vegetated areas designed to treat sheet flow runoff from adjacent impervious surfaces or intensive landscaped areas such as golf courses. Filter strips decrease runoff velocity, filter out total suspended solids and associated pollutants, and provide some infiltration into underlying soils. While some assimilation of dissolved constituents may occur, filter strips are generally more effective in trapping sediment and particulate-bound metals, nutrients, and pesticides. Filter strips are more effective when the runoff passes through the vegetation and thatch layer in the form of shallow, uniform flow. Biological and chemical processes may help break down pesticides, uptake metals, and use nutrients that are trapped in the filter.

Vegetated filter strip captures runoff from freeway

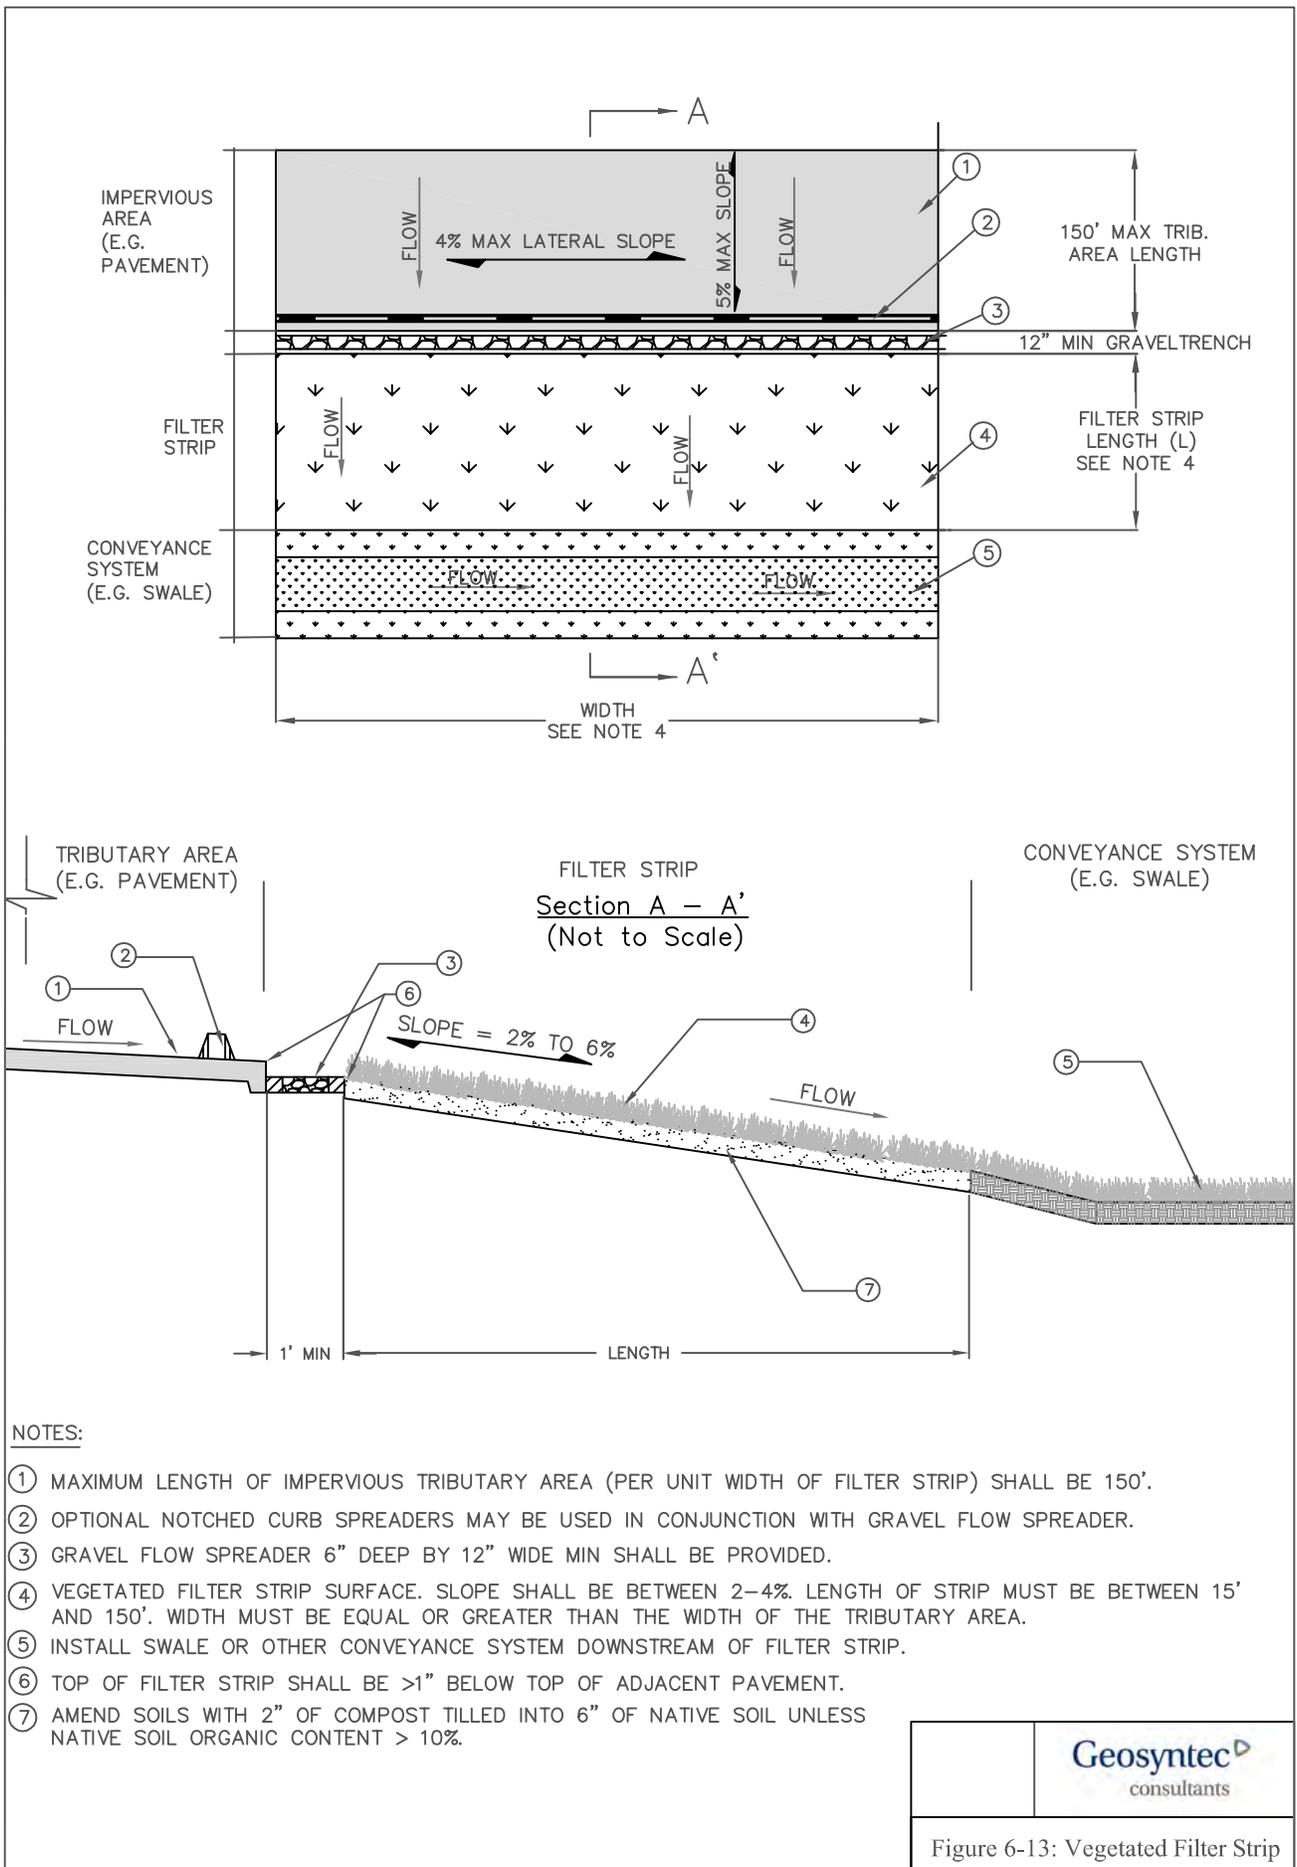

Photo Credit: Washington Department of Transportation

Applications

- Areas adjacent to parking lots and driveways
- Road medians and shoulders

Preventative Maintenance

- Remove excess sediment
- Stabilize/repair minor erosion and scouring
- Remove trash and debris
- Mow regularly

Limitations

The following describes limitations for vegetated filter strips:

- High flow velocity - steep terrain and/or large tributary area may cause concentrated, erosive flows.
- Sheet flow - shallow, evenly-distributed flow across the entire width of the filter strip is required. Filter strips are designed to treat small areas. The maximum flow path from a contributing impervious surface should not exceed 150 feet. Flows should enter as sheet flow and not exceed a depth of 1 inch.
- Shallow grades – a limited site slope may cause ponding.
- Availability of pervious area adjacent to impervious area - filter strips require sheet flow from impervious areas.

Design Criteria

The main challenge associated with filter strips is maintaining sheet flow, which is critical to the performance of this BMP. If flows are concentrated, then little or no treatment of stormwater runoff is achieved and erosive rilling is likely. The use of a flow spreading device (e.g., gravel trench or level spreader) to deliver shallow, evenly-distributed sheet flow to the strip is required. Vegetated filter strips should be designed according to the requirements listed in Table 6-21 and outlined in the section below. BMP sizing worksheets are presented in Appendix E.

Table 6-21: Vegetated Filter Strip Design Criteria

Design Parameter	Unit	Design Criteria
Stormwater quality design flow (SQDF)	cfs	See Section 2 and Appendix E for calculating SQDF.
Maximum design flow depth	inches	1
Design residence time	minutes	7
Design flow velocity	ft/sec	< 1 ft/sec
Minimum length in flow direction	feet	15 (25 preferred); If sized for pretreatment only, filter strip can be a minimum of 4.
Maximum length (parallel to flow) of tributary area per unit width (perpendicular to flow) of filter strip	feet	150
Minimum slope in flow direction	%	2

Design Parameter	Unit	Design Criteria
Maximum slope in flow direction	%	4
Maximum lateral slope	%	4
Vegetation	-	Turf grass (irrigated) or approved equal
Minimum grass height	inches	2
Maximum grass height	inches	4 (typical) or as required to prevent shading
Elevation of flow spreader	inches	> 1 inch below the pavement surface

Sizing Criteria

The flow capacity of a vegetated filter strips (filter strips) is a function of the longitudinal slope (parallel to flow), the resistance to flow (e.g., Manning’s roughness), and the width and length of the filter strip. The slope should be shallow enough to ensure that the depth of water will not exceed 1 inch over the filter strip. Similarly, the flow velocity should be less than 1 ft/sec. Procedures for sizing filter strips are summarized below. A filter strip sizing example is also provided.

Step 1: Calculate the design flow rate

The design flow is calculated based on the SQDF (see Section 2).

Step 2: Calculate the minimum width

Determine the minimum width (W_{min}), perpendicular to flow, allowable for the filter strip and design for that width or larger.

$$W_{min} = (SQDF) / (q_{a,min}) \tag{Equation 6-33}$$

Where

W_{min} = minimum width of filter strip (and tributary area)

$SQDF$ = design flow (cfs)

$q_{a,min}$ = minimum linear unit application rate, 0.005 cfs/ft

Step 3: Calculate the design flow depth

The design flow depth (d_f) is calculated based on the width and the slope, parallel to the flow path, using a modified Manning’s equation as follows:

$$d_f = 12 \times [SQDF * n_{wq} / 1.49W_{trib} s^{0.5}]^{0.6} \tag{Equation 6-34}$$

Where:

d_f	=	design flow depth (inches)
$SQDF$	=	design flow (cfs)
W	=	width of strip (perpendicular to flow = width of impervious surface contributing area (ft))
s	=	slope (ft/ft) of strip parallel to flow, average over the whole width
n_{wq}	=	Manning's roughness coefficient (0.25-0.30)

If d_f is greater than 1 inch (0.083 ft), then a shallower slope is required, or a filter strip cannot be used.

Step 4: Calculate the design velocity

The design flow velocity (V_{wq}) is based on the design flow, design flow depth, and width of the strip:

$$V_{wq} = SQDF / (d_f W) \quad \text{(Equation 6-35)}$$

Where:

$d_{f,ft}$	=	design flow depth (ft) ($d_f/12$)
$SQDF$	=	stormwater quality design flow (cfs)
W	=	width of strip (perpendicular to flow = width of impervious surface contributing area (ft))

Step 5: Calculate the desired length of the filter strip

Determine the required length (L) to achieve a desired minimum residence time of 7 minutes using:

$$L = 60t_{hr} * V_{wq} \quad \text{(Equation 6-36)}$$

Where:

L	=	minimum allowable strip length (ft)
t_{hr}	=	hydraulic residence time (min)
V_{wq}	=	design flow velocity (fps) calculated by Equation 6-35

Geometry and Size

- 1) The width of the filter strip shall extend across the full width of the tributary area. The upstream boundary of the filter should be located contiguous to the developed tributary area.
- 2) The length (in direction of flow) should be between 15 and 150 feet. A minimum length of 25 feet is preferred. Filter strips used for pretreatment shall be at least 4 feet long (in direction of flow).
- 3) Filter strips shall be designed on slopes (parallel to the direction of flow) between 2% and 4%; steeper slopes tend to result in concentrated flow. Slopes less than 2% could pond runoff, and in poorly permeable soils, create a mosquito breeding habitat.
- 4) The lateral slope of strip (parallel to the edge of the pavement, perpendicular to the direction of flow) should be 4% or less.
- 5) Grading should be even: a filter strip with uneven grading perpendicular to the flow path will develop flow channels over time.
- 6) The top of the strip should be installed 2 to 5 inches below the adjacent pavement to allow for vegetation and sediment accumulation at the edge of the strip. A beveled transition is acceptable and may be required per roadside design specifications.
- 7) Both the top and toe of the slope should be as flat as possible to encourage sheet flow and prevent channeling and erosion. For engineered filter strips, the facility surface should be graded flat prior to placement of vegetation.

Energy Dissipation / Level Spreading

Runoff entering a filter strip must not be concentrated. A flow spreader should be installed at the edge of the pavement to uniformly distribute the flow along the entire width of the filter strip.

- 1) At a minimum, a gravel flow spreader (gravel-filled trench) should be placed between the impervious area contributing flows and the filter strip, and meet the following requirements:
 - a. The gravel flow spreader should be a minimum of 6 inches deep and should be 12 inches wide.
 - b. The gravel should be a minimum of 1 inch below the pavement surface. *The intention is that this allows sediment from the paved surface to be accommodated without blocking drainage onto the strip.*
- 2) The gravel flow spreader should be a minimum of 6 inches deep and should be 12 inches wide.

- a. Where the ground surface is not level, the gravel spreader must be installed so that the bottom of the gravel trench and the outlet lip are level.
 - b. Along roadways, gravel flow spreaders must be placed and designed in accordance with County road design specifications for compacted road shoulders.
- 3) Curb ports and interrupted curbs may only be used in conjunction with a gravel spreader to better ensure that water sheet flows onto the strip, provided:
- a. Curb ports use fabricated openings that allow concrete curbing to be poured or extruded while still providing an opening through the curb to admit water to the filter strip. Interrupted curbs are sections of curb placed to have gaps spaced at regular intervals along the total width of the treatment area. Openings or gaps in the curb should be at regular intervals but at least every 6 feet. The width of each opening should be a minimum of 11 inches.
 - b. At a minimum, gaps should be every 6 feet to allow distribution of flows into the treatment facility before they become too concentrated. The opening should be a minimum of 11 inches. Approximately 15 percent or more of the curb section length should be in open ports, and as a general rule, no opening should discharge more than 10 percent of the overall flow entering the facility.
- 4) Energy dissipaters are needed in a filter strips if sudden slope drops occur, such as locations where flows in a filter strip pass over a rockery or retaining wall aligned perpendicular to the direction of flow. Adequate energy dissipation at the base of a drop section can be provided by a riprap pad.

Access

- 1) Access should be provided at the upper edge of a filter strip to enable maintenance of the inflow spreader throughout the strip width and allow access for mowing equipment.

Water Depth and Velocity

- 1) The design water depth shall not exceed 1 inch.
- 2) Runoff flow velocities should not exceed approximately 1 foot per second across the filter strip surface.

Soils

Filter strip soils should be amended with 2 inches of compost, unless the organic content is already greater than 10%. The compost should be mixed into the native soils to a depth of 6 inches to prevent soil layering and washout of compost. The compost will contain no sawdust, green or under-composted material, or any other toxic or harmful substance. It

should contain no un-sterilized manure which can lead to high levels of potentially pathogenic bacteria in the runoff.

Vegetation

Filter strips must be uniformly graded and densely vegetated with erosion-resistant grasses that effectively bind the soil. Native or adapted grasses are preferred because they generally require less fertilizer and are more drought-resistant than exotic plants. The following vegetation guidelines should be followed for filter strips:

- 1) Sod (turf) can be used instead of grass seed, as long as there is complete coverage.
- 2) Irrigation should be provided to establish the grasses.
- 3) Grasses or turf should be maintained at a height of 2 to 4 inches. Regular mowing is often required to maintain the turf grass cover.
- 4) Trees or shrubs should not be used in abundance because they shade the turf and impede sheet flow.

Operations and Maintenance

Filter strips mainly require vegetation management. Therefore little special training is needed for maintenance crews. Typical maintenance activities and frequencies include:

- 1) Inspect strips at least twice annually for erosion or damage to vegetation, preferably at the end of the wet season to schedule summer maintenance and in the fall to ensure the strip is ready for winter. However, additional inspection after periods of heavy runoff is most desirable. The strip should be checked for debris and litter and areas of sediment accumulation (see Appendix I for a vegetated filter strip inspection and maintenance checklist).
- 2) Mow as frequently as necessary (at least twice a year) for safety and aesthetics or to suppress weeds and woody vegetation.
- 3) Trash tends to accumulate in strip areas, particularly along roadways. The need for litter removal should be determined through periodic inspection. Litter should always be removed prior to mowing.
- 4) Regularly inspect vegetated buffer strips for pools of standing water. Vegetated filter strips can become a nuisance due to mosquito breeding in level spreaders (unless designed to dewater completely in less than 72 hours), in pools of standing water if obstructions develop (e.g. debris accumulation, invasive vegetation), and/or if proper drainage slopes are not implemented and maintained.
- 5) Activities that lead to ruts or depressions on the surface of the filter strip should be prevented or the integrity of the strip should be restored by leveling and reseeded. Examples are vehicle tracks, utility maintenance, and pedestrian (short-cut) tracks.

- 6) Vegetation should be healthy and dense enough to provide filtering, while protecting underlying soils from erosion:
- Mulch should be replenished as needed to ensure survival of vegetation.
 - Vegetation, large shrubs or trees that interfere with landscape swale operation should be pruned.
 - Fallen leaves and debris from deciduous plant foliage should be removed.
 - Filter strips should be mowed to 4 to 6 inches height. Grass clippings should be removed.
 - Invasive vegetation, such as Alligatorweed (*Alternanthera philoxeroides*), Halogeton (*Halogeton glomeratus*), Spotted Knapweed (*Centaurea maculosa*), Giant Reed (*Arundo donax*), Castor Bean (*Ricinus communis*), Perennial Pepperweed (*Lepidium latifolium*), and Yellow Starthistle (*Centaurea solstitialis*) should be removed and replaced with non-invasive species. Invasive species should never contribute more than 10% of the vegetated area. For more information on invasive weeds, including biology and control of listed weeds, look at the [encycloweedia](#) located at the California Department of Food and Agriculture website or the California Invasive Plant Council website at www.cal-ipc.org.
 - Dead vegetation should be removed if greater than 10% of area coverage or when filter strip function is impaired. Vegetation should be replaced and established before the wet season to maintain cover density and control erosion where soils are exposed.

BIO-5: Proprietary Biotreatment

Proprietary biotreatment devices are manufactured treatment BMPs that incorporate plants, soil, and microbes engineered to provide treatment at higher flow rates or volumes and with smaller footprints than their non-proprietary counterparts. Incoming flows are typically pretreated to remove larger particles/debris, filtered through a planting media (mulch, compost, soil, and plants), collected by an underdrain, and delivered to the stormwater conveyance system.

Application

- Parking lot islands
- Pickup/drop off turnarounds
- Roadway curbs

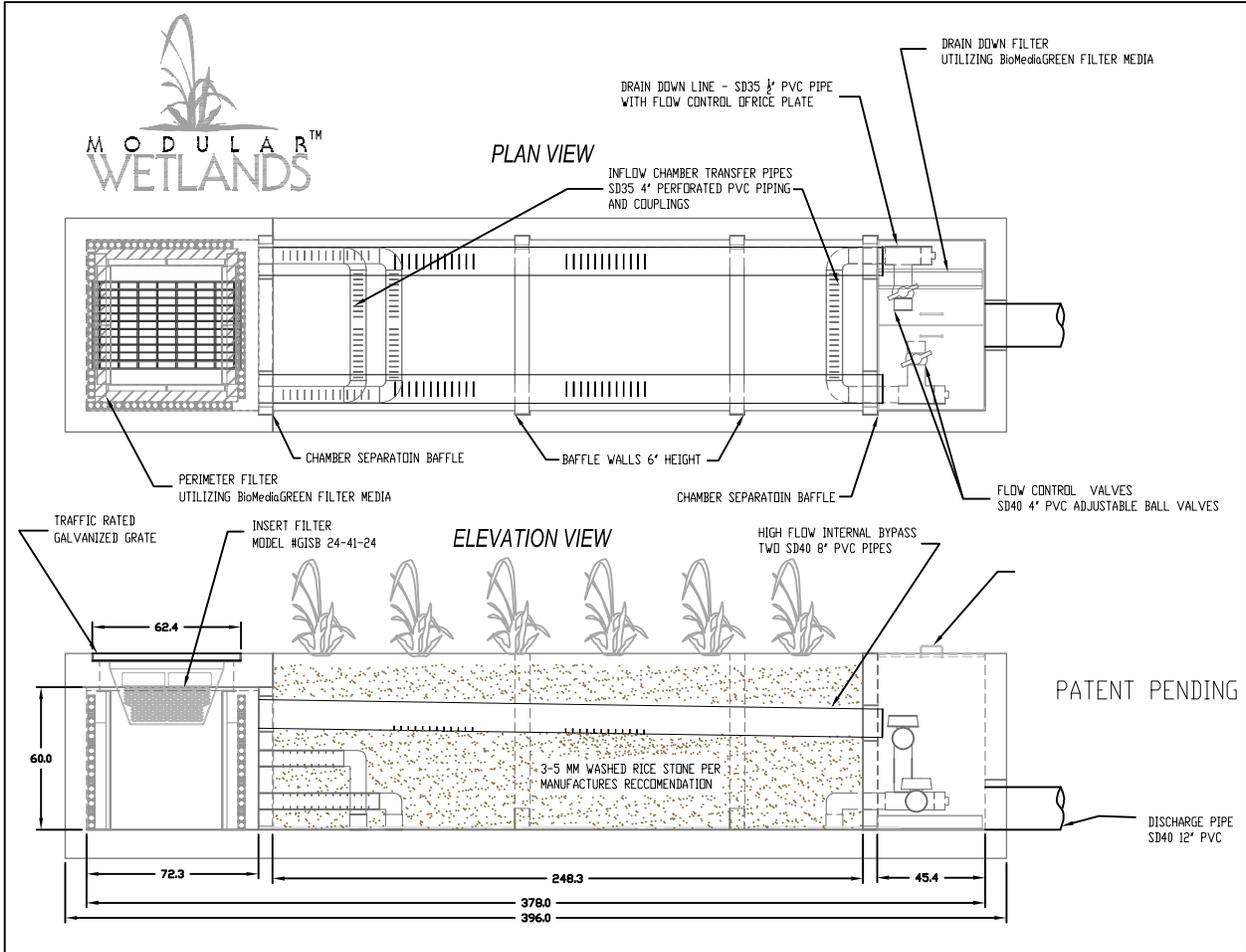

Maintenance

- Filter media replacement
- Sediment, trash, and debris removal
- Mulch replacement
- Vegetation upkeep and replacement

TCM-1: Dry Extended Detention Basin

Dry extended detention (ED) basins are basins whose outlets have been designed to detain the SQDV for 36 to 48 hours to allow sediment particles and associated pollutants to settle and be removed. Dry ED basins do not have a permanent pool. They are designed to drain completely between storm events. They can also be used to provide hydromodification and/or flood control by modifying the outlet control structure and providing additional detention storage. The slopes, bottom, and forebay of dry ED basins are typically vegetated. Without the addition of a sand filter beneath the basin, considerable stormwater volume reduction can still occur, depending on the infiltration capacity of the subsoil.

Extended Detention Basin Application

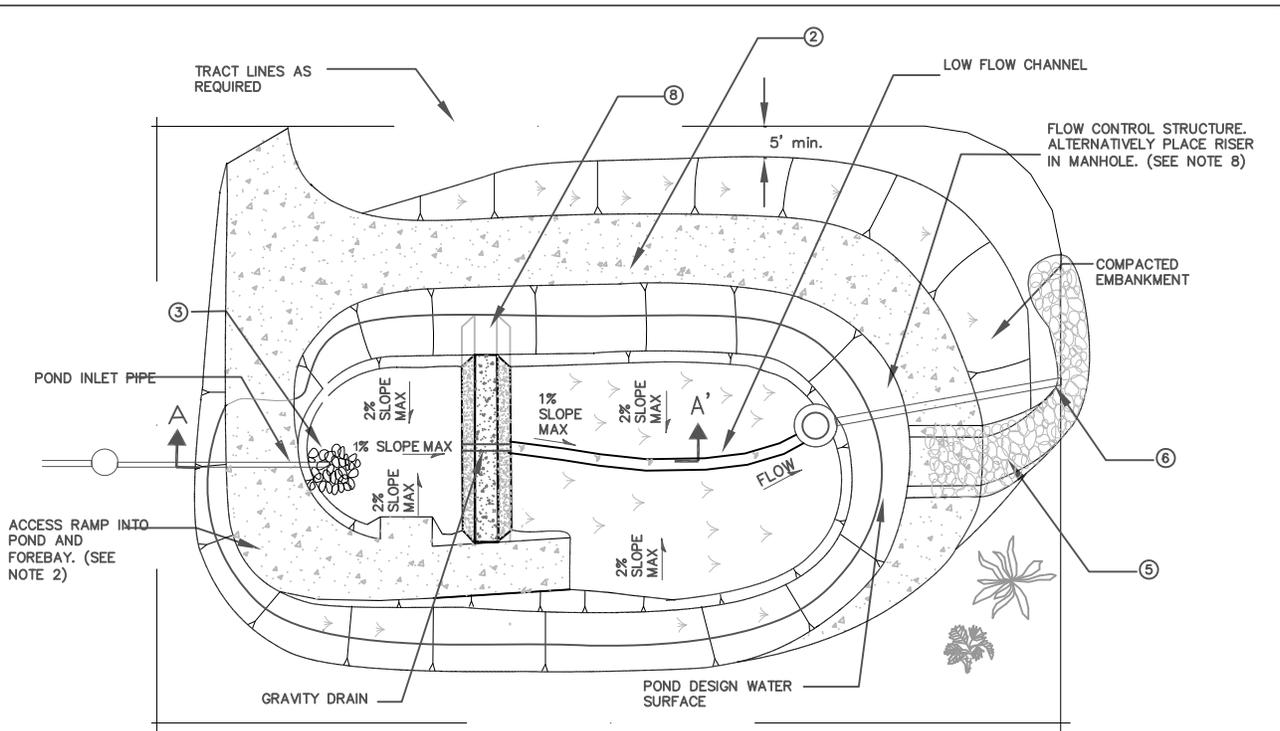

Photo Credit: Geosyntec Consultants

Application

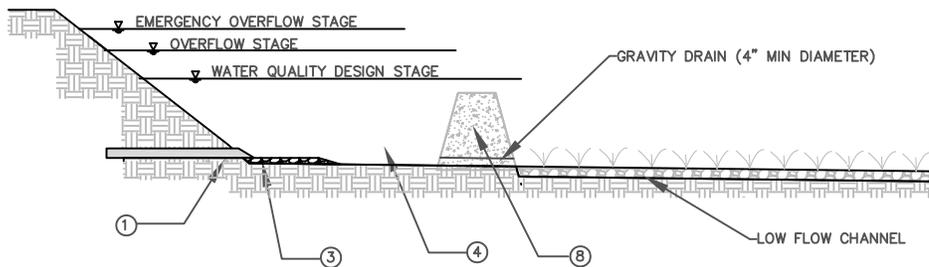

- Adjacent to parking lots
- Road medians and shoulders
- Within open areas or play fields

Preventative Maintenance

- Remove trash and debris, minor sediment accumulation, and obstructions near inlet and outlet structures
- Replace top 2 to 4 inch of sand
- Mow or weed surface of filter

Plan View
(Not to Scale)

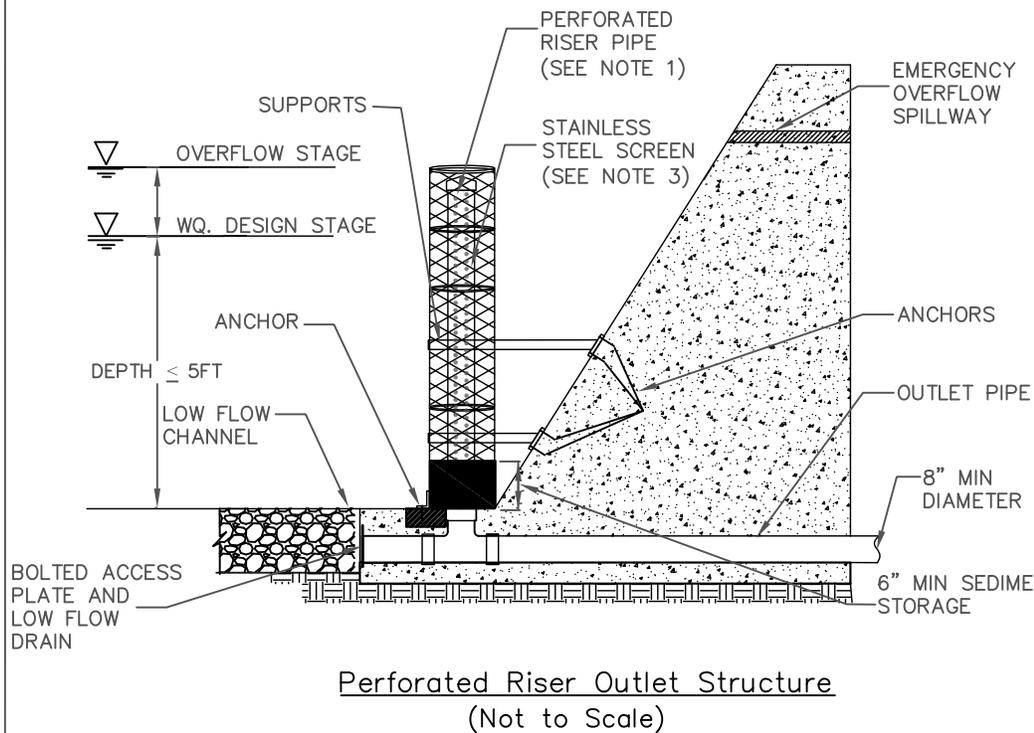

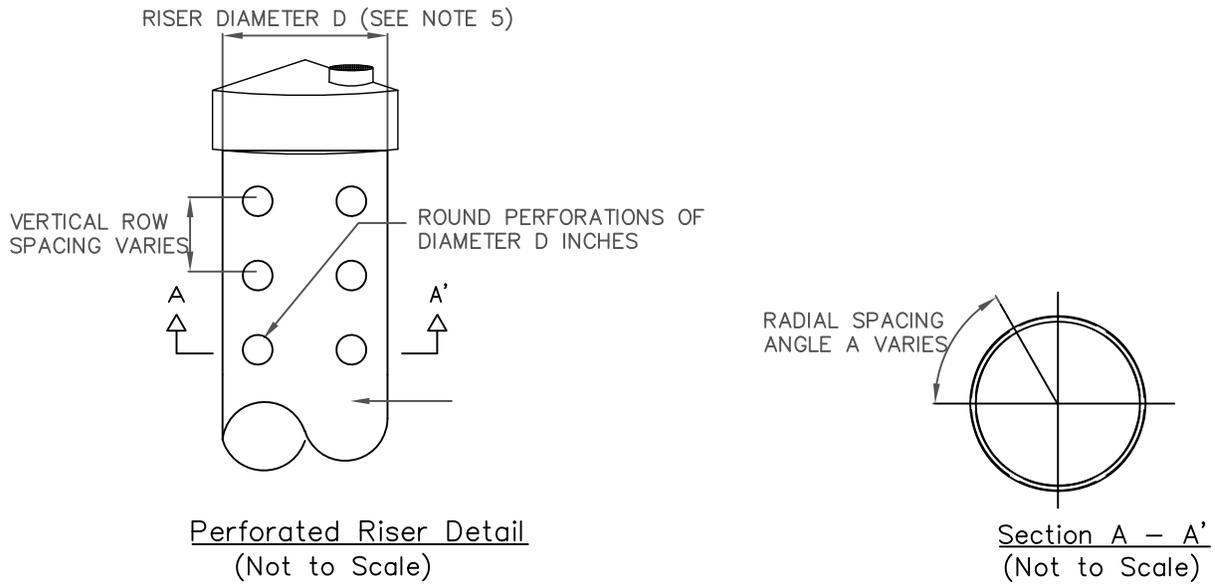

Section A - A'
(Not to Scale)

NOTES:

- ① INLET PIPE SHALL BE DESIGNED AND LOCATED SO THAT NON-EROSIVE VELOCITIES OCCUR IN THE FOREBAY
- ② MAINTENANCE RAMP SHOULD PROVIDE ACCESS TO BOTH THE FOREBAY AND MAIN BASIN.
- ③ RIP RAP APRON OR OTHER INLET ENERGY DISSIPATION SHALL BE PROVIDED SUCH THAT VELOCITIES IN THE FOREBAY ARE < 4 FT/S.
- ④ SEDIMENT FOREBAY SHOULD BE SIZED TO PROVIDE 5-15% OF THE TOTAL BASIN VOLUME.
- ⑤ EMERGENCY SPILLWAY MUST BE SIZED TO PASS 100-YEAR PEAK FLOW FOR ON-LINE BASINS, AND WATER QUALITY DESIGN FLOW FOR OFF-LINE BASINS.
- ⑥ OUTLET PIPE. ENERGY DISSIPATION SHALL BE PROVIDED UNLESS DISCHARGE IS TO PIPE OR HARDENED CHANNEL.
- ⑦ OUTLET STRUCTURE SHOULD BE SIZED TO DRAIN WATER QUALITY VOLUME IN 36 - 48 HOURS (SEE FIGURE 2-2 FOR PERFORATED RISER DETAILS). ALTERNATIVELY PLACE RISER STRUCTURE IN A MANHOLE (SEE FIGURE 2-3).
- ⑧ INSTALL EARTHEN BERM OR EQUIVALENT. TOP OF BERM SHALL BE 2' MINIMUM BELOW DESIGN WATER QUALITY STAGE. BERM SHALL BE KEYED INTO EMBANKMENT A MINIMUM OF 1' ON BOTH SIDES.

NOTES:

1. ALTERNATIVE SPILLWAY DESIGNS BASED ON THE CALIFORNIA DEPARTMENT OF WATER RESOURCES' GUIDELINES FOR THE DESIGN AND CONSTRUCTION OF SMALL EMBANKMENT DAMS OR AT THE DISCRETION OF THE DEPARTMENT

Figure 6-18: Spillway

Limitations

Limitations for dry extended detention basins include:

- Surface space availability - typically 0.5 to 2.0 percent of the total tributary development area required.
- Depth to groundwater - bottom of basin should be 2 feet higher than the seasonal high water table elevation.
- Steep slopes - basins placed above slopes greater than 15 percent or within 200 feet from the top of a hazardous slope or landslide area require a geotechnical investigation.
- Compatibility with flood control - basins must not interfere with flood control functions of existing conveyance and detention structures.

Design Criteria

Dry extended detention basins should be designed according to the requirements listed in Table 6-23 and outlined in the section below. BMP sizing worksheets are presented in Appendix E.

Table 6-23: Dry Extended Detention Basin Design Criteria

Design Parameter	Unit	Design Criteria
Stormwater quality design volume (SQDV)	acre-feet	See Section 2 and Appendix E for calculating SQDV
Drawdown time for SQDV	hours	Top 50%: 12 hrs (minimum); Bottom 50%: 36 hrs
Basin Design Volume	acre-ft	1.2 * SQDV
Forebay basin size	acre-feet	5 to 15% of SQDV
Maximum forebay drain time	min	45
Low-flow channel depth	inches	9
Low-flow channel flow capacity		2*forebay outlet rate
Freeboard (minimum)	inches	12
Flow path length to width ratio	L:W	2:1, larger preferred; can be achieved using internal berms
Longitudinal slope	percentage	1 (forebay) and 0-2 (main basin)
Low flow channel geometry	feet	depth of 0.5 and width of 1
Minimum outflow device diameter	inches	18

Sizing Criteria

Dry extended detention (ED) basins are basins designed such that the SQDV is detained for 48 hours. This allows sediment particles and associated pollutants to settle and be removed from the stormwater. Procedures for sizing extended detention basins are summarized below. A sizing example is also provided.

Step 1: Calculate the design volume

Dry extended detention facilities shall be sized to capture and treat the SQDV (see Section E.1).

Step 2: Calculate the volume of the active basin

The total basin volume should be increased an additional 20% above the SQDV to account for sediment accumulation, at a minimum. If the basin is designed only for water quality treatment then the basin volume would be 120% of the SQDV. Freeboard is in addition to the total basin volume. Calculate the volume of the active basin (V_a):

$$V_a = 1.20 * \text{SQDV} \quad (\text{Equation 6-37})$$

Step 3: Determine detention basin location and preliminary geometry based on site constraints

Based on site constraints, determine the basin geometry (area and length) and the storage available by developing an elevation-storage relationship for the basin. The cross-sectional geometry across the width of the basin should be approximately trapezoidal. Shallow side slopes are necessary if the basin is designed to have recreational uses during dry weather conditions.

- 1) Calculate the width of the basin footprint (W_{tot}) as follows:

$$W_{tot} = \frac{A_{tot}}{L_{tot}} \quad (\text{Equation 6-38})$$

Where:

A_{tot} = total surface area of the basin footprint (ft²)

L_{tot} = total length of the basin footprint (ft)

- 2) Calculate the length of the active volume surface area including the internal berm but excluding the freeboard, (L_{av-tot}):

$$L_{av-tot} = L_{tot} - 2Zd_{fb} \quad (\text{Equation 6-39})$$

Where:

Z = interior side slope as length per unit height (H:V)

d_{fb} = freeboard depth (ft)

- 3) Calculate the width of the active volume surface area including the internal berm but excluding freeboard (ft), (W_{av-tot}):

$$W_{av-tot} = W_{tot} - 2Zd_{fb} \quad (\text{Equation 6-40})$$

- 4) Calculate the total active volume surface area including the internal berm and excluding freeboard, (A_{av-tot}):

$$A_{av-tot} = L_{av-tot} \times W_{av-tot} \quad (\text{Equation 6-41})$$

- 5) Calculate the area of the berm, (A_{berm}):

$$A_{berm} = W_{berm} \times L_{berm} \quad (\text{Equation 6-42/43})$$

Where:

W_{berm} = width of the internal berm

L_{berm} = length of the internal berm (= width excluding freeboard, W_{av-tot})

- 6) Calculate the surface area excluding the internal berm and freeboard, A_{av} :

$$A_{av} = A_{av-tot} - A_{berm} \quad (\text{Equation 6-44})$$

Step 4: Determine Dimensions of Forebay

The forebay should be sized to at least 5 to 15% of the basin active volume (V_a). Calculate the active volume of the forebay, (V_1):

$$V_1 = \frac{V_a \times \%V_1}{100} \quad (\text{Equation 6-45})$$

Where:

$\%V_1$ = percent of V_a in forebay (%)

V_a = total active volume (ft³)

- 7) Calculate the surface area for the active volume of forebay (A_1):

$$A_1 = \frac{V_1}{d_1} \quad (\text{Equation 6-46})$$

Where:

$$d_1 = \text{average depth for the forebay (ft)}$$

- 8) Calculate the length of forebay, (L_1):

$$L_1 = \frac{A_1}{W_1} \quad (\text{Equation 6-47})$$

Where:

$$W_1 = \text{width of forebay (ft)}$$

Step 5: Determine Dimensions of Cell 2

Cell 2 will consist of the remainder of the basin's active volume.

- 1) Calculate the active volume of Cell 2, (V_2):

$$V_2 = V_a - V_1 \quad (\text{Equation 6-48})$$

Where:

$$V_a = \text{total basin active volume (ft}^3\text{)}$$

$$V_1 = \text{volume of forebay (ft}^3\text{)}$$

- 2) Calculate the surface area, A_2 , for the active volume of Cell 2:

$$A_2 = A_{av} - A_1 \quad (\text{Equation 6-49})$$

Where:

$$A_{av} = \text{basin surface area excluding berm and freeboard (ft}^2\text{)}$$

$$A_1 = \text{surface area of forebay (ft}^2\text{)}$$

- 3) Calculate the average depth (d_2) for the active volume of Cell 2:

$$d_2 = \frac{V_2}{A_2} \quad (\text{Equation 6-50})$$

- 4) Calculate the length of Cell 2, (L_2):

$$L_2 = \frac{A_2}{W_2} \quad (\text{Equation 6-51})$$

Where:

$$W_2 = \text{width of Cell 2 (ft)}$$

- 5) Verify that the length-to-width ratio of Cell 2 at half of d_2 is at least 1.5:1 with $\geq 2:1$ preferred. If the length-to-width ratio is less than 1.5:1, modify input parameters until a ratio of at least 1.5:1 is achieved. If the input parameters cannot be modified as a result of site constraints, another site for the basin should be chosen. Calculate the length-to width (LW_{mid2}) ratio of Cell 2 at half of d_2 follows:

$$LW_{mid2} = \frac{L_{mid2}}{W_{mid2}} \quad (\text{Equation 6-52})$$

Where:

$$W_{mid2} = W_2 - Zd_2 \quad (\text{Equation 6-53})$$

$$L_{mid2} = L_2 - Zd_2 \quad (\text{Equation 6-54})$$

$$W_{mid2} = \text{width of Cell 2 at half of } d_2 \text{ (ft)}$$

$$L_{mid2} = \text{length of Cell 2 at half of } d_2 \text{ (ft)}$$

$$Z = \text{interior side slope as length per unit height (H:V)}$$

$$d_2 = \text{cell 2 average depth (ft)}$$

Step 6: Ensure Design Requirements and Site Constraints are achieved

Check design requirements and site constraints. Modify design geometry until requirements are met. If the chosen site for the basin is inadequate to meet the design requirements, choose a new location or alternative treatment BMP.

Step 7: Size Outlet Structure

The total drawdown time for the basin should be 48 hours. The outlet structure should be designed to release the bottom 50% of the detention volume (half-full to empty) over 36 hours, and the top half (full to half-full) in 12 hours. A primary overflow should be sized to pass the peak flow rate from the developed capital design storm. See Section 6 for outlet structure sizing methodologies.

Step 8: Determine Emergency Spillway Requirements

For online basins, an emergency overflow spillway should be sized to pass flows greater than the design peak runoff discharge rate for the 100-yr, 24-hr storm in order to prevent overtopping of the walls or berms in the event that a blockage of the riser occurs. For offline basins, an emergency spillway or riser should be sized to pass the 100-yr, 24-hr post-development peak stormwater runoff discharge rate directly to the downstream conveyance system or another acceptable discharge point. For sites where the emergency

spillway discharges to a steep slope, an emergency overflow riser, in addition to the spillway should be provided.

Sizing and Geometry

- 1) The total basin volume should be increased an additional 20% of the SQDV to account for sediment accumulation, at a minimum. If the basin is designed only for water quality treatment then the basin volume would be 120% of the SQDV. Freeboard is in addition to the total basin volume.
- 2) The minimum freeboard should be at least 1 foot above the emergency overflow water surface for dry extended detention basins.
- 3) The minimum flow-path length to width ratio at half basin height should be a minimum of 3:1 (L:W) and can be achieved using internal berms or other means to prevent short-circuiting. Intent: a long flow length will improve fine sediment removal.
- 4) The cross-sectional geometry across the width of the basin should be approximately trapezoidal. Shallow side slopes are necessary if the basin is designed to have recreational uses during dry weather conditions.
- 5) All dry ED basins should be free draining and a low flow channel should be provided. A low flow channel is a narrow, shallow trench filled with pea gravel and encased with filter fabric that runs the length of the basin to drain dry weather flows. The low flow channel should be of sufficient size considering the natural characteristics of the soil and have a positive-draining gradient flowing toward the outlet structure (typically 1 ft wide by 6 inches deep). If infiltration rates of subsurface soils are insufficient, the low flow channel should tie into perforated pipe at the outlet structure. If a sand filter or planting media is provided beneath the dry ED basin for increased volume reduction, it may be designed to take the place of the low flow channel.
- 6) The basin bottom should have a 1% longitudinal slope (direction of flow) in the forebay, and may range from 0 to 2% longitudinal slope in the main basin. The bottom of the basin should slope 2% toward the center low flow channel.
- 7) A basin should be large enough to allow for equipment access via a graded ramp.

Soils Considerations

- 1) The slopes of the detention basin should be analyzed for slope stability using rapid drawdown conditions and should meet the minimum standards set by the Ventura County Flood Control District. A 1.5 static factor of safety should be used. Seismic analysis is not required due to the temporary storage of water in the basin.
- 2) The infiltration capability of the dry ED basin can be enhanced by incorporating soil amendments.

Energy Dissipation

- 1) Energy dissipation controls constructed of sound materials such as stones, concrete, or proprietary devices that are rated to withstand the energy of the influent flow should be installed at the inlet to the sediment forebay. Flow velocity into the basin forebay should be controlled to 4 feet per second (ft/sec) or less.
- 2) Energy dissipation controls must also be used at the outlet/spillway from the detention basin unless the basin discharges to a storm drain or hardened channel.

Sediment Forebay

As untreated stormwater enters the dry ED basin, it passes through a sediment forebay for coarse solids removal. The forebay may be constructed using an internal berm constructed out of earthen embankment material, grouted riprap, stop logs, or other structurally sound material.

- 1) The basin should be sized so that 5 to 15% of the total basin volume is in the forebay and 85 to 95% of the total basin volume is in the main portion of the basin.
- 2) A gravity drain outlet from the forebay (2 inch minimum diameter) should extend the entire width of the internal berm and be designed to completely drain to the main basin within 10 minutes.
- 3) The forebay outlet should be offset (horizontally) from the inflow streamline to prevent short-circuiting.
- 4) Permanent steel post depth markers should be placed in the forebay to define sediment removal limits at 50% of the forebay sediment storage depth.

Vegetation

Vegetation within the dry ED basin provides erosion protection from wind and water and biofiltration of stormwater. The local permitting authority should review and approve any proposed basin landscape plan prior to implementation and following guidelines should be followed:

- 1) The bottom and slopes of the dry ED basin should be vegetated. A mix of erosion-resistant plant species that effectively bind the soil should be used on the slopes and a diverse selection of plants that thrive under the specific site, climatic, and watering conditions should be specified for the basin bottom. The basin bottom should not be planted with trees, shrubs, or other large woody plants that may interfere with sediment removal activities. The basin should be free of floating objects. Only native perennial grasses, forbs, or similar vegetation that can be replaced via seeding should be used on the basin bottom.
 - a. Landscaping outside of the basin is required for all dry ED basins and should adhere to the following criteria so as not to hinder maintenance operations:

- b. No trees or shrubs may be planted within 15 feet of inlet or outlet pipes or manmade drainage structures such as spillways, flow spreaders, or earthen embankments. Species with roots that seek water, such as willow or poplar, should not be used within 50 feet of pipes or manmade structures. Weeping willow (*Salix babylonica*) should not be planted in or near detention basins.
- 2) Prohibited non-native plant species will not be permitted. For more information on invasive weeds, including biology and control of listed weeds, look at the [encycloveedia](#) located at the California Department of Food and Agriculture website- or the California Invasive Plant Council website at www.cal-ipc.org.
- 3) A plant list provided by a landscape professional should be used as a guide only and should not replace project-specific planting recommendations, including recommendations on appropriate plants, fertilizer, mulching applications, and irrigation requirements (if any) to ensure healthy vegetation growth.

Sand Filter or Planting Media Layer

For increasing the volume reduction capability of a dry ED basin, an appropriately sized sand filter or planting media layer can be placed beneath the dry ED basin to achieve desired volume reduction goals if soil and slope conditions allow (i.e., infiltration rate greater than 0.5 in/hr but less than 2.4 in/hr; site slope less than 15%). The drawdown time of the sand filter or planting media layer should be less than 72 hours. The base of the sand filter or planting media layer should be level (i.e., zero slope). If a sand filter/planting media layer is provided over the length of the basin, it can take the place of the low-flow channel so long as it is designed to adequately infiltrate dry weather flows. Sizing of the sand filter and planting media layer for dry ED basins is the same as for [sand filters](#) and [bioretention](#) areas, respectively. The depth of water in the dry ED basin should not exceed 6 feet.

Outlet Structure and Drawdown Time

A drawdown time of 36 to 48 hours shall be provided for the SQDV. This drawdown time is for the volume in the basin above the sand filter layer (if provided) and serves the purpose of water quality treatment. An outflow device should be designed to release the bottom 50% of the detention volume (half-full to empty) over 24 to 32 hours, and the top half (full to half-full) in 12 to 16 hours. *The intention is that the drawdown schemes that detain low flows for longer periods than high flows have the following advantages over outlets that drain the basin evenly:*

- Greater flood control capabilities
- Enhanced treatment of low flows which make up the bulk of incoming flows.

Additional storage, detention, and outlet control is required to achieve pre-development stormwater runoff discharge rates for hydromodification control. The outlet structure

can be designed to achieve flow control for meeting the multiple objectives of water quality and flow attenuation.

The outflow device (i.e., outlet pipe) should be oversized (18 inch minimum diameter). There are two options that can be used for the outlet structure:

- 1) Uniformly perforated riser structures.
- 2) Multiple orifice structures (orifice plate).

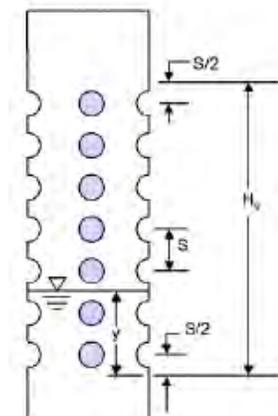

The outlet structure can be placed in the basin with a debris screen (Figure 6-15) or housed in a standard manhole (Figure 6-16). If a multiple orifice structure is used, an orifice restriction (if necessary) should be used to limit orifice outflow to the maximum discharge rates allowable for achieving the desired water quality and flow control objectives. Orifice restriction plates should be removable for emergency situations. A removable trash rack should be provided at the outlet.

Note that a primary overflow (typically a riser pipe connected to the outlet works) should be sized to pass flows larger than the stormwater quality design storm (if the ED basin is sized only for water quality) or to pass flows larger than the peak flow rate of the maximum design storm to be detained in the basin (e.g., 100-yr, 24-hr). The primary overflow is intended to protect against overtopping or breaching of a basin embankment.

Perforated Risers Outlet Sizing Methodology

The following attributes influence the perforated riser outlet sizing calculations:

- Shape of the basin (e.g., trapezoidal)
- Depth and volume of the basin
- Elevation / depth of first row of holes
- Elevation / depth of last row of holes
- Size of perforations
- Number of rows or perforations and number of perforations per row
- Desired drawdown time (e.g., 16 hour and 32 hour draw down for top half and bottom half respectively, 48 hour total drawdown time for the stormwater quality design volume)

Perforated Riser Outlet

Geosyntec Consultants

The governing rate of discharge from a perforated riser structure can be calculated using Equation 6-44 below:

$$Q = C_p \frac{2A_p}{3H_s} \sqrt{2g} H^{3/2} \quad (\text{Equation 6-55})$$

Where:

- Q = riser flow discharge (cfs)
- C_p = discharge coefficient for perforations (use 0.61)
- A_p = cross-sectional area of all the holes (ft²)
- s = center to center vertical spacing between perforations (ft)
- H_s = distance from $s/2$ below the lowest row of holes to $s/2$ above the top row of holes (McEnroe 1988).
- H = effective head on the orifice (measured from center of orifice to water surface)

For the iterative computations needed to size the perforations in the riser and determine the riser height, a simplified version of Equation 6-44 may be used as shown below in Equation 6-45 and Equation 6-46:

$$Q = kH^{3/2} \quad (\text{Equation 6-56})$$

Where:

- H = effective head on the orifice (measured from center of orifice to water surface)

$$k = C_p \frac{2A_p}{3H_s} \sqrt{2g} \quad (\text{Equation 6-57})$$

Where:

- C_p = discharge coefficient for perforations (use 0.61)
- A_p = cross-sectional area of all the holes (ft²)
- s = center to center vertical spacing between perforations (ft)

H_s	=	distance from $s/2$ below the lowest row of holes to $s/2$ above the top row of holes.
g	=	32.17 ft/sec ²

Uniformly perforated riser designs are defined by the depth or elevation of the first row of perforations, the length of the perforated section of pipe, and the size or diameter of each perforation.

Multiple Orifice Outlet Sizing Methodology

The following attributes influence multiple orifice outlet sizing calculations:

- Shape of the basin (e.g., trapezoidal)
- Depth and volume of the basin
- Elevation of each orifice
- Desired draw-down time (e.g., 16 hour and 32 hour draw down times for top half and bottom half respectively, 48 hour drawdown time for stormwater quality design volume)

The rate of discharge from a single orifice can be calculated using Equation 6-22.

$$Q = CA(2gH)^{0.5} \quad \text{(Equation 6-58)}$$

Where:

Q	=	orifice flow discharge
C	=	discharge coefficient
A	=	cross-sectional area of orifice or pipe (ft ²)
g	=	acceleration due to gravity (32.2 ft/s ²)
H	=	effective head on the orifice (measured from center of orifice to water surface)

Multiple orifice designs are defined by the depth (or elevation) and the size (or diameter) of each orifice. The steps needed to size a dual orifice outlet are outlined in Appendix E; multiple orifices may be provided and sized using a similar approach.

Emergency Spillway

An emergency overflow spillway in addition to the primary overflow outlet (as described above) is required. The emergency spillway should be sized for flows greater than the

peak 100-year 24-hour storm if the basin is designed on-line or, if the basin is designed on-line, the spillway should be sized for flows greater than the basin design volume (e.g., stormwater quality design volume). The spillway should provide for adequate energy dissipation downstream. The spillway should allow for at least 12 inches of freeboard above the emergency overflow water surface elevation if the basin is on-line. If the basin is on-line, 2 feet of freeboard is preferable.

Spillways shall meet the California Department of Water Resources, Division of Safety of Dams Guidelines for the Design and Construction of Small Embankment Dams (<http://damsafety.water.ca.gov/docs/GuidelinesSmallDams.pdf>). *Intent: Emergency overflow spillways are intended to control the location of basin overtopping and safely direct overflows back into the downstream conveyance system or other acceptable discharge point.*

On-line Basins

- 1) On-line basins must have an emergency overflow spillway to prevent overtopping of walls or berms should blockage of the primary outlet occur based on a downstream risk assessment.
- 2) The overflow spillway must be sized to pass flows greater than the design peak runoff discharge rate for the 100-yr, 24-hr storm.
- 3) The minimum freeboard should be 1 foot (but preferably at least 2 feet) above the maximum water surface elevation over the emergency spillway.

Off-line Basins

- 1) Off-line basins must have either an emergency overflow spillway or an emergency overflow riser. The emergency overflow must be designed to pass the 100-yr 24-hr post-development peak stormwater runoff discharge rate directly to the downstream conveyance system or another acceptable discharge point. Where an emergency overflow spillway would discharge to a steep slope, an emergency overflow riser, in addition to the spillway should be provided.
- 2) The emergency overflow spillway shall be armored to withstand the energy of the spillway flows.
- 3) The minimum freeboard should be 1 foot above the maximum water surface elevation over the emergency spillway.

Side Slopes

- 1) Interior side slopes above the stormwater quality design depth and up to the emergency overflow water surface steeper than 4:1 (H:V) should be stabilized to prevent erosion with a method approved by the local permitting authority.

- 2) Exterior side slopes steeper than 2:1 (H:V) should be stabilized to prevent erosion with a method approved by the local permitting authority.
- 3) For any slope (interior or exterior) greater than 2:1 (H:V), a geotechnical investigation and report must be submitted and approved by the local permitting authority.
- 4) Landscaped slopes should be no greater than 3:1 (H:V) to allow for maintenance.
- 5) Basin walls may be vertical retaining walls, provided: (a) they are constructed of reinforced concrete, (b) a fence is provided along the top of the wall (see fencing below) or further back, and (c) the design is stamped by a licensed civil engineer and approved by the Local permitting authority.

Embankments

- 1) Earthworks and berm embankments should be performed in accordance with the latest edition of the “Greenbook Standard Specifications for Public Works Construction”.
- 2) Embankments are earthen slopes or berms used for detaining or redirecting the flow of water.
- 3) Top of berm separating forebay and main basin should be 2 feet minimum below the stormwater quality design water surface and should be keyed into embankment a minimum of 1 foot on both sides.
- 4) Typically, the top width of berm embankments are at least 20 feet, but narrower embankments may be plausible if approved by the civil engineer and the Local permitting authority.
- 5) Basin berm embankments should be constructed on native consolidated soil (or adequately compacted and stable fill soils analyzed by a licensed civil engineer) free of loose surface soil materials, roots, and other organic debris.
- 6) The berm embankment should be constructed of compacted soil (95% minimum dry density, modified proctor method per ASTM D1557), placed in 6-inch lifts.
- 7) Basin berm embankments greater than 4 feet in height should be constructed by excavating a key equal to 50% of the berm embankment cross-sectional height and width. This requirement may be waived if specifically recommended by a licensed civil engineer.
- 8) The berm embankment should be constructed of compacted soil (95% minimum dry density, modified proctor method per ASTM D1557), placed in 6-inch lifts.
- 9) Low growing native or non-invasive perennial grasses should be planted on downstream embankment slopes. See vegetation section below.

Fencing

- 1) Safety is provided either by fencing of the facility or by managing the contours of the basin to eliminate drop-offs and other hazards.
- 2) If fences are required, fences should be designed and constructed in accordance with relevant standards and should typically be located at or above the overflow water surface elevation. Shrubs (approved, California-adapted species) can be used to hide the fencing. See vegetation section above.

Right-of-Way

- 1) Dry extended detention basins and associated access roads to be maintained by a public agency should be dedicated in fee or in an easement to the public agency with appropriate access.

Maintenance Access

- 1) Ownership of the basin and maintenance thereof is the responsibility of the developer/applicant. A maintenance agreement with the Local permitting authority is required to ensure adequate performance and allow emergency access to the facilities.
- 2) Maintenance access road(s) should be provided to the control structure and other drainage structures associated with the basin (e.g., inlet, emergency overflow or bypass structures). Manhole and catch basin lids should be in or at the edge of the access road.
- 3) A ramp into the basin should be constructed near the basin outlet. An access ramp is required for removal of sediment with a backhoe or loader and truck. The ramp should extend to the basin bottom to avoid damage to vegetation planted on the basin slope.
- 4) All access ramps and roads should be provided in accordance with the current policies of the Ventura County Flood Control District or local approval authority.

Construction Considerations

The use of treated wood or galvanized metal anywhere inside the facility is prohibited.

Operations and Maintenance

Maintenance is of primary importance if extended detention basins are to continue to function as originally designed. A maintenance agreement must be developed with the local approval authority to ensure adequate performance and allow emergency access. Maintenance of the basin is the responsibility of the development, unless otherwise agreed upon.

A specific maintenance plan shall be formulated for each facility outlining the schedule and scope of maintenance operations, as well as the data handling and reporting requirements. The following are general maintenance requirements:

- 1) The basin should be inspected semiannually or more frequently, and inspections after major storm events are encouraged (see Appendix I for guidance on facility maintenance inspections). Trash and debris should be removed as needed, but at least annually prior to the beginning of the wet season (see Appendix I for dry extended detention basin inspection and maintenance checklist).
- 2) Site vegetation should be maintained as follows:
 - Vegetation, large shrubs, or trees that limit access or interfere with basin operation should be pruned or removed.
 - Slope areas that have become bare should be revegetated and eroded areas should be regraded prior to being revegetated.
 - Grass should be mowed to 4 to 9 inch high and grass clippings should be removed.
 - Fallen leaves and debris from deciduous plant foliage should be raked and removed.
 - Invasive vegetation, such as Alligatorweed (*Alternanthera philoxeroides*), Halogeton (*Halogeton glomeratus*), Spotted Knapweed (*Centaurea maculosa*), Giant Reed (*Arundo donax*), Castor Bean (*Ricinus communis*), Perennial Pepperweed (*Lepidium latifolium*), and Yellow Starthistle (*Centaurea solstitialis*) should be removed and replaced with non-invasive species. Invasive species should never contribute more than 25% of the vegetated area. For more information on invasive weeds, including biology and control of listed weeds, look at the [encyclopedia](#) located at the California Department of Food and Agriculture website or the California Invasive Plant Council website at www.cal-ipc.org.
 - Dead vegetation should be removed if it exceeds 10% of area coverage. Vegetation should be replaced immediately to maintain cover density and control erosion where soils are exposed.
 - No herbicides or other chemicals should be used to control vegetation.
- 3) Sediment buildup exceeding 50% of the forebay capacity should be removed. Sediment from the remainder of the basin should be removed when 6 inches of sediment accumulates. Sediments should be tested for toxic substance accumulation in compliance with current disposal requirements if land uses in the catchment include commercial or industrial zones, or if visual or olfactory indications of pollution are noticed. If toxic substances are encountered at concentrations exceeding thresholds of Title 22, Section 66261 of the California Code of Regulations,

the sediment must be disposed of in a hazardous waste landfill. It is recommended to clean the forebay frequently to reduce frequency of main basin cleaning.

- 4) Remove sediment from basin when accumulation reaches 25% of original design depth. Cleaning is recommended to occur in early spring to allow vegetation to reestablish.
- 5) Repair erosion to banks and bottom of basin as required.
- 6) Following sediment removal activities, replanting, and/or reseeding of vegetation may be required for reestablishment.
- 7) Control vectors as needed.

TCM-2: Wet Detention Basin

Wet detention basins are constructed, naturalistic ponds with a permanent or seasonal pool of water (also called a “wet pool” or “dead storage”). Aquascape facilities, such as artificial lakes, are a special form of wet pool facility that can incorporate innovative design elements to allow them to function as a stormwater treatment facility in addition to an aesthetic water feature. Wetponds require base flows to exceed or match losses through evaporation and/or infiltration and they must be designed with the outlet positioned and/or operated in such a way as to maintain a permanent pool. Wetponds can be designed to provide extended detention of incoming flows using the volume above the permanent pool surface.

Wet Detention Basin

Photo Credit: Geosyntec Consultants

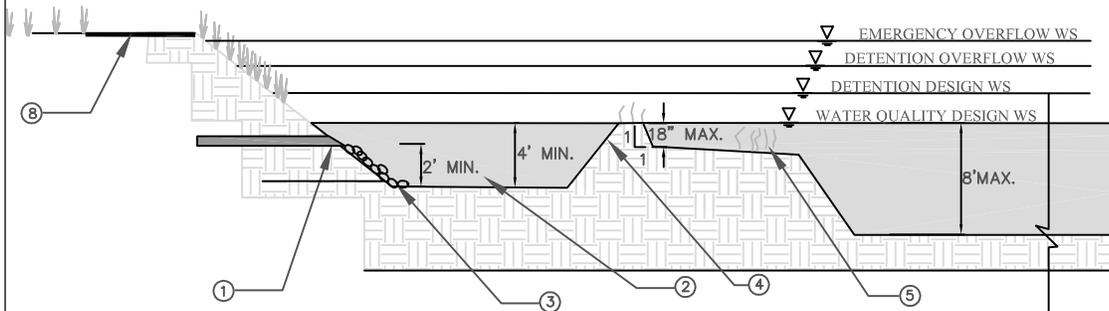

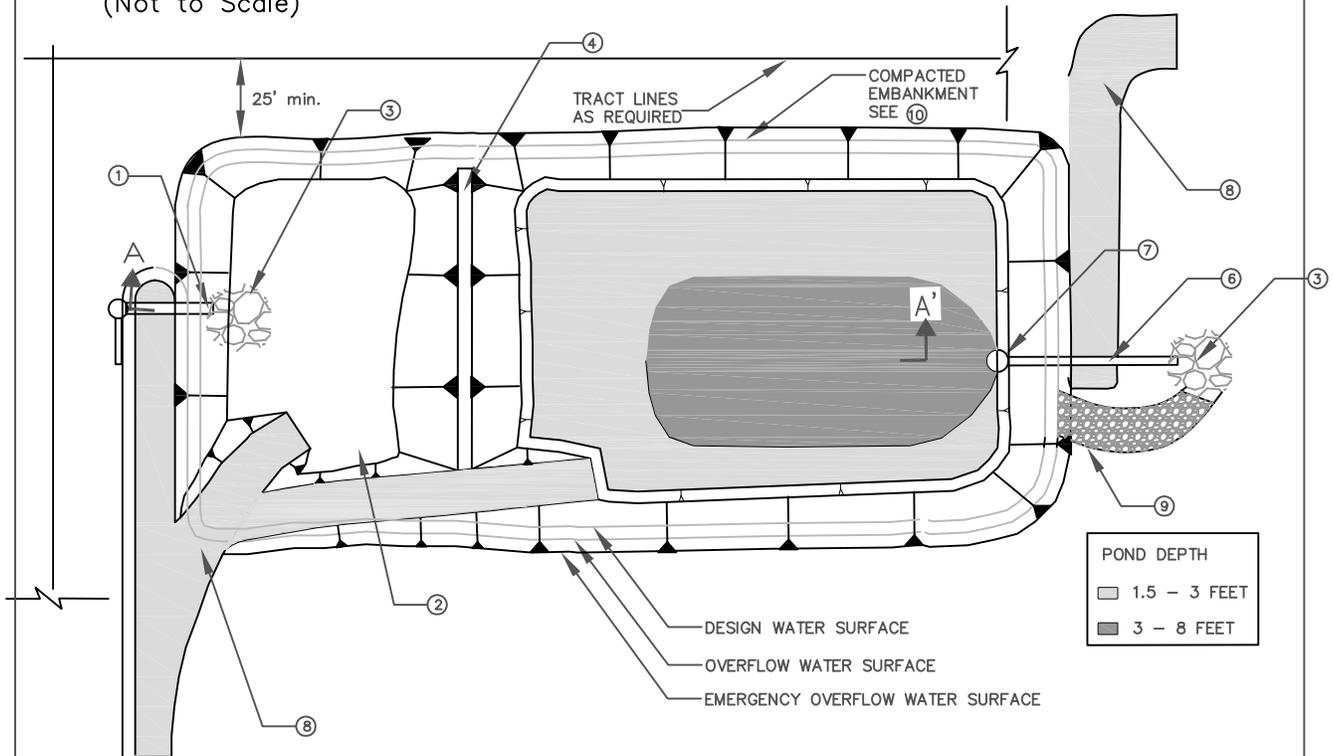

Application

- Regional detention & treatment
- Roads, highways, parking lots, commercial, residential
- Parks, open spaces, and golf courses

Preventative Maintenance

- inspected at a minimum annually and inspections after major storm events
- Pruned or remove vegetation, large shrubs, or trees that limit access or interfere with basin operation
- Remove sediment buildup at inlets and outlets

Plan View
(Not to Scale)

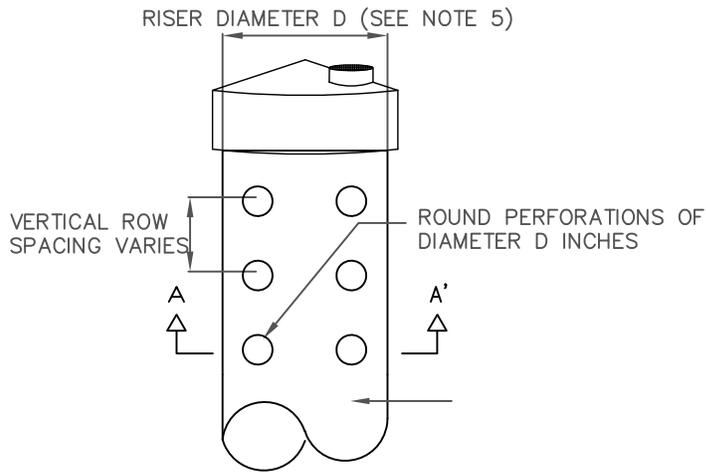

Section A - A'
(Not to Scale)

NOTES:

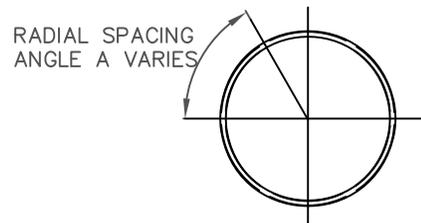

- ① INLET PIPE SHOULD BE SUBMERGED WITH A MINIMUM OF 2' DISTANCE FROM THE BOTTOM
- ② FIRST CELL VOLUME SHALL EQUAL 25% TO 35% OF TOTAL WETPOND VOLUME. DEPTH SHALL BE 4' MIN TO 8' MAX PLUS AN ADDITIONAL 1' MIN SEDIMENT STORAGE DEPTH.
- ③ RIP RAP APRON OR OTHER ENERGY DISSIPATION.
- ④ BERM SHALL EXTEND ACROSS ENTIRE WIDTH OF THE WETPOND.
- ⑤ EMERGENT VEGETATION SHALL BE PLANTED IN REGIONS OF THE POND THAT ARE 3' DEEP OR LESS.
- ⑥ SIZE OUTLET PIPE TO PASS 100-YEAR PEAK FLOW FOR ON-LINE PONDS AND WATER QUALITY PEAK FLOW FOR OFF-LINE PONDS.
- ⑦ WATER QUALITY OUTLET STRUCTURE. SEE FIGURE 8-2 AND FIGURE 8-3 FOR DETAILS.
- ⑧ MAINTENANCE ACCESS ROAD SHOULD PROVIDE ACCESS TO BOTH THE FIRST CELL AND MAIN BASIN.
- ⑨ INSTALL EMERGENCY OVERFLOW SPILLWAY AS NEEDED. SEE FIGURE 2-4 FOR DETAILS

(Not to Scale)

Perforated Riser Outlet Structure
(Not to Scale)

NOTES:

- ① RISER PIPE SHALL BE SIZED TO PROVIDE 36 TO 48-HOUR FULL BRIM DRAW DOWN TIME.
- ② TOTAL OUTLET CAPACITY: 100-YEAR PEAK FLOW FOR ON-LINE BASINS AND WATER QUALITY DESIGN FLOW FOR OFF-LINE BASINS.
- ③ SCREEN OPENINGS SHALL BE AT LEAST 1/4" AND SHALL NOT EXCEED THE DIAMETER OF THE PERFORATIONS ON THE RISER.
- ④ RISER PIPE PERFORATION DIAMETER SHALL BE NO LESS THAN 1/2" AND NO MORE THAN 2"
- ⑤ MINIMUM PIPE DIAMETER (D) IS 2'
- ⑥ RISER PIPE MATERIAL IS CMP

Figure 6-20: Riser Outlet

Inverted Pipe Outlet Structure
(Not to Scale)

NOTES:

- ① SIZE OUTLET PIPE SYSTEM TO PASS 100-YEAR FLOW FOR ON-LINE PONDS AND WATER QUALITY PEAK FLOW FOR OFF-LINE PONDS.
- ② VALVE MAY BE LOCATED INSIDE MANHOLE OR OUTSIDE WITH APPROVED OPERATIONAL ACCESS
- ③ INVERT OF DRAIN SHALL BE 6" MINIMUM BELOW TOP OF INTERNAL BERM. LOWER PLACEMENT IS DESIRABLE. INVERT SHALL BE 6" MINIMUM ABOVE BOTTOM OF POND.
- ④ OUTLET PIPE INVERT SHALL BE AT WETPOOL WATER SURFACE ELEVATION

	
<p>Figure 6-21: Inverted Pipe Outlet</p>	

Limitations

Limitations for wet detention basins include:

- Wet detention basins typically are used for treating areas larger than 10 acres and less than 10 square miles. They are especially applicable for regional water quality treatment and flow control.
- Off-line wet detention basins must not interfere with flood control functions of existing conveyance and detention structures.
- If wet detention basins are located in areas with site slopes greater than 15% or within 200 feet of a hazardous steep slope or mapped landslide area (on the uphill side), a geotechnical investigation and report must be provided to ensure that the basin does not compromise the stability of the site slope or surrounding slopes.
- Wet detention basins require a regular source of base flow if water levels are to be maintained. If base flow is insufficient during summer months, supplemental water may be necessary to maintain water levels.

Design Criteria

The main challenge associated with wet detention basins is maintaining desired water levels. A wet detention basin should be designed according to the requirements listed in Table 6-24 and outlined in the section below. BMP sizing worksheets are presented in Appendix E.

Table 6-24: Wet Detention Basin Design Criteria

Design Parameter	Unit	Design Criteria
Stormwater quality design volume, SQDV	acre-ft	See Section 2 and Appendix E for calculating SQDV.
Permanent Pool Volume		SQDV
Forebay Volume		5 to 10% of SQDV
Maximum Forebay Drain Time	min	45
Depth without sediment storage	feet	0.5-12 (littoral zone, 25-40% permanent pool) 4 (first cell minimum) 8 (any cell maximum) Deeper zone: 4-8 feet average; 12 feet maximum depth
Maximum residence time	Days	7 (dry weather)
Freeboard (minimum)	inches	12

Flow path length to width ratio	L:W	2:1 (larger preferred)
Side slope (maximum)	H:V	4:1 (H:V) Interior and 3:1 (H:V) Exterior
Longitudinal slope	percentage	1 (forebay) and 0-2 (main basin)
Vegetation Type	--	Varies see vegetation section below
Vegetation Height	--	Varies see vegetation section below
Buffer zone (minimum)	feet	25
Minimum outflow device diameter	inches	18

Sizing Criteria

Wet Detention basins may be designed with or without extended detention above the permanent pool. The extended detention portion of the wet detention basin above the permanent pool, if provided, functions like a dry extended detention (ED) basin (see [VEG-5: Dry Extended Detention Basin](#)). If there is no extended detention provided, wet detention basins shall be sized to provide a minimum wet pool volume equal to the stormwater quality design volume plus an additional 5% for sediment accumulation. If extended detention is provided above the permanent pool, the sizing is dependent of the functionality of the basin; the basin may function as water quality treatment only or water quality plus peak flow attenuation.

If the basin is designed for water quality treatment only, then the permanent pool volume should be a minimum of 10 percent of the stormwater quality design volume and the surcharge volume (above the permanent pool) should make up the remaining 90 percent. If extended detention is provided above the permanent pool and the basin is designed for water quality treatment and peak flow attenuation, then the permanent pool volume should be equal to the water quality treatment volume, and the surcharge volume should be sized to attenuate peak flows in order to meet the peak runoff discharge requirements. The extended detention portion of the wet detention basin above the permanent pool, if provided, functions like a dry extended detention (ED) basin (see [VEG-5: Dry Extended Detention Basin](#)).

Step 1: Calculate the design volume

Wet detention basins shall be sized with a permanent pool volume equal to the SQDV volume (see [Section 2](#) and Appendix E).

Step 2: Determine the active design volume for the wet detention basin without extended detention

The active volume of the wet detention basin, V_a , shall be equal to the SQFV plus an additional 5% for sediment accumulation.

$$V_a = 1.05 \times SQDV \quad (\text{Equation 6-59})$$

Step 3: Determine pond location and preliminary geometry based on site constraints

Based on site constraints, determine the pond geometry and the storage available by developing an elevation-storage relationship for the pond. Note that a more natural geometry may be used and is in many cases recommended; the preliminary basin geometry calculations should be used for sizing purposes only.

- 1) Calculate the width of the pond footprint, W_{tot} , as follows:

$$W_{tot} = \frac{A_{tot}}{L_{tot}} \quad (\text{Equation 6-60})$$

Where:

A_{tot} = total surface area of the pond footprint (ft²)

L_{tot} = total length of the pond footprint (ft)

- 1) Calculate the length of the active volume surface area including the internal berm but excluding the freeboard, L_{av-tot} :

$$L_{av-tot} = L_{tot} - 2Zd_{fb} \quad (\text{Equation 6-61})$$

Where:

Z = interior side slope as length per unit height

d_{fb} = freeboard depth

- 2) Calculate the width of the active volume surface area including the internal berm but excluding freeboard, W_{av-tot} :

$$W_{av-tot} = W_{tot} - 2Zd_{fb} \quad (\text{Equation 6-62})$$

- 3) Calculate the total active volume surface area including the internal berm and excluding freeboard, A_{av-tot} :

$$A_{av-tot} = L_{av-tot} \times W_{av-tot} \quad (\text{Equation 6-63})$$

- 4) Calculate the area of the berm, A_{berm} :

$$A_{berm} = W_{berm} \times L_{berm} \quad (\text{Equation 6-64})$$

Where:

W_{berm} = width of the internal berm

L_{berm} = length of the internal berm

- 5) Calculate the active volume surface area excluding the internal berm and freeboard, A_{wq} :

$$A_{wq} = A_{wq = tot} - A_{berm} \quad (\text{Equation 6-65})$$

Step 4: Determine Dimensions of Forebay

The wet detention basin should be divided into two cells separated by a berm or baffle. The forebay should contain between 5 and 10 percent of the total volume. The berm or baffle volume should not count as part of the total volume. Calculate the active volume of forebay, V_1 :

$$V_1 = \frac{V_a \times \%V_1}{100} \quad (\text{Equation 6-66})$$

Where:

$\%V_1$ = percent of SQDV in forebay (%)

- 1) Calculate the surface area for the active volume of forebay, A_1 :

$$A_1 = \frac{V_1}{d_1} \quad (\text{Equation 6-67})$$

Where:

d_1 = average depth for the active volume of forebay (ft)

- 1) Calculate the length of forebay, L_1 . Note, inlet and outlet should be configured to maximize the residence time.

$$L_1 = \frac{A_1}{W_1} \quad (\text{Equation 6-68})$$

Where:

W_1 = width of forebay (ft), $W_1 = W_{av-tot} = L_{berm}$

Step 5: Determine Dimensions of Cell 2

Cell 2 will consist of the remainder of the basin's active volume.

- 1) Calculate the active volume of Cell 2, V_2 :

$$V_2 = V_a - V_1 \quad (\text{Equation 6-69})$$

- 2) The minimum wetpool surface area includes 0.3 acres of wetpool per acre-foot of permanent wetpool volume. Calculate A_{min2} :

$$A_{min2} = (V_2 \times 0.3 \frac{\text{acres}}{\text{acre-foot}}) \quad (\text{Equation 6-70})$$

- 3) Calculate the actual wetpool surface area, A_2 :

$$A_2 = A_{av} - A_1 \quad (\text{Equation 6-71})$$

Verify that A_2 is greater than A_{min2} . If A_2 is less than A_{min2} , then modify input parameters to increase A_2 until it is greater than A_{min2} . If site constraints limit this criterion, then another site for the pond should be chosen.

- 4) Calculate the top length of Cell 2, L_2 :

$$L_2 = \frac{A_2}{W_2} \quad (\text{Equation 6-72})$$

Where:

$$W_2 = \text{width of Cell 2 (ft), } W_2 = W_1 = W_{wq\text{-tot}} = L_{\text{berm}}$$

- 5) Verify that the length-to-width ratio of Cell 2 is at least 1.5:1 with $\geq 2:1$ preferred. If the length-to-width ratio is less than 1.5:1, modify input parameters until a ratio of at least 1.5:1 is achieved. If the input parameters cannot be modified as a result of site constraints, another site for the pond should be chosen.

$$LW_2 = \frac{L_2}{W_2} \quad (\text{Equation 6-73})$$

- 6) Calculate the emergent vegetation surface area, A_{ev} :

$$A_{ev} = \frac{A_2 \bullet \% A_{ev}}{100} \quad (\text{Equation 6-74})$$

Where:

$$\%A_{ev} = \text{percent of surface area that will be planted with emergent vegetation}$$

- 7) Calculate the volume of the emergent vegetation shallow zone (1.5 – 3 ft), V_{ev} :

$$V_{ev} = A_{ev} \bullet d_{ev} \quad (\text{Equation 6-75})$$

Where:

$$d_{ev} = \text{average depth of the emergent vegetation shallow zone (1.5 – 3 ft)}$$

8) Calculate the length of the emergent vegetation shallow zone, L_{ev} :

$$L_{ev} = \frac{A_{ev}}{W_{ev}} \quad (\text{Equation 6-76})$$

Where:

$$W_{ev} = \text{width of the emergent vegetation shallow zone (ft), } W_{ev} = W_2$$

9) Calculate the volume of the deep zone, V_{deep} :

$$V_{deep} = V_2 - V_{ev} \quad (\text{Equation 6-77})$$

10) Calculate the surface area of the deep (>3 ft) zone, A_{deep} :

$$A_{deep} = A_2 - A_{ev} \quad (\text{Equation 6-78})$$

11) Calculate the average depth of the deep zone (4-8 ft), d_{deep} :

$$d_{deep} = \frac{V_{deep}}{A_{deep}} \quad (\text{Equation 6-79})$$

12) Calculate length of the deep zone, L_{deep} :

$$L_{deep} = \frac{A_{deep}}{W_{deep}} \quad (\text{Equation 6-80})$$

Where:

$$W_{deep} = \text{width of the deep zone (ft), } W_{deep} = W_2$$

Step 6: Ensure design requirements and site constraints are achieved

Check design requirements and site constraints. Modify design geometry until requirements are met. If the chosen site for the basin is inadequate to meet the design requirements, choose a new location for the BMP.

Step 7: Size Outlet Structure

For extended detention wet detention basin, outlet structures should be designed to provide 12 to 48 hour emptying time for the water quality volume above the permanent pool.

The basin outlet pipe should be sized, at a minimum, to pass flows greater than the stormwater quality design peak flow for off-line basins or flows greater than the peak runoff discharge rate for the 100-year, 24-hr design storm for on-line basins.

Step 8: Determine Emergency Spillway Requirements

For online basins, an emergency overflow spillway should be sized to pass flows greater than the design peak runoff discharge rate for the 100-yr, 24-hr storm to prevent overtopping of the walls or berms in the event that a blockage of the riser occurs. For offline basins, an emergency spillway or riser should be sized to pass the water quality design storm. For sites where the emergency spillway discharges to a steep slope, an emergency overflow riser, in addition to the spillway should be provided.

Sizing and Geometry

- 1) If there is no extended detention provided, wet detention basins shall be sized to provide a minimum wet pool volume equal to the stormwater quality design volume plus an additional 5% for sediment accumulation. If extended detention is provided above the permanent pool and the basin is designed for water quality treatment only, then the permanent pool volume should be a minimum of 10 percent of the stormwater quality design volume and the surcharge volume (above the permanent pool) should make up the remaining 90 percent. If extended detention is provided above the permanent pool and the basin is designed for water quality treatment and peak flow attenuation, then the permanent pool volume shall be equal to the water quality treatment volume and the surcharge volume should be sized to attenuate peak flows to meet the peak runoff discharge requirements. The extended detention portion of the wet detention basin above the permanent pool, if provided, functions like a dry extended detention (ED) basin (see TCM-1: Dry Extended Detention Basin).
- 2) The wet detention basin should be divided into two cells separated by a berm or baffle. The first cell should contain between 25 to 35 percent of the total volume. The berm or baffle volume should not count as part of the total volume. Intent: The full-length berm or baffle reduces short-circuiting and promotes plug flow.
- 3) Wet detention basins with wetpool volumes less than or equal to 4,000 cubic feet may be single-celled (i.e., no baffle or berm is required).
- 4) Sediment storage should be provided in the first cell. The sediment storage should have a minimum depth of 1 foot. This volume should not be included as part of the required water quality volume.
- 5) The minimum depth of the first cell should be 4 feet, exclusive of sediment storage requirements. The depth of the first cell may be greater than the depth of the second cell. Average depth should be between 4 feet and 8 feet.
- 6) For wet detention basin depths in excess of 6 feet, some form of recirculation should be provided, such as a fountain or aerator, to prevent stratification, stagnation and low dissolved oxygen conditions.

- 7) The edge of the basin should slope from the surface of the permanent pool to a depth of 12 to 18 inches at a slope of 1:1 or greater. If soil conditions will not support a 1:1 (H:V) slope then the steepest slope that can be supported should be used or a shallow retaining wall constructed (18 inch max). Beyond the edge of the basin, a bench sloped at 4:1 (H:V) maximum should extend into the basin to a depth of at least 3 feet. A steeper slope may be used beyond the 3 foot depth to a maximum of 8 feet. Intent: steep slopes at water's edge will minimize very shallow areas that can support mosquitoes.
- 8) At least 25% of the basin area should be deeper than 3 feet to prevent the growth of emergent vegetation across the entire basin. If greater than 50% of the wet pool area is in excess of 6 feet deep, some form of recirculation should be provided, such as a fountain or aerator, to prevent stratification, stagnation and low dissolved oxygen conditions.
- 9) A wet detention basin should have a surface area of not less than 0.3 acres for each acre-foot of permanent pool volume. In addition, extra area needed to provide a design that meets all other provisions of this section should be provided. Additional surface area in excess of the minimum may be provided. There is no maximum surface area provided that all provisions of this section are met.
- 10) Inlets and outlets should be placed to maximize the flowpath through the facility. The flowpath length-to-width ratio should be a minimum of 1.5:1, but a flowpath length-to-width ratio of 2:1 or greater is preferred. The flowpath length is defined as the distance from the inlet to the outlet, as measured at mid-depth. The width at mid-depth can be found as follows: $\text{width} = (\text{average top width} + \text{average bottom width})/2$. Intent: a long flowpath length will improve fine sediment removal.
- 11) All inlets should enter the first cell. If there are multiple inlets, the length-to-width ratio should be based on the average flowpath length for all inlets.
- 12) The minimum freeboard should be 1 foot above the maximum water surface elevation (2 feet preferred) for on-line basins and 1 foot above the maximum water surface elevation for on-line basins.
- 13) The maximum residence time for dry weather flows should be 7 days. Intent: Vector control.

Internal Berms and Baffles

- 1) A berm or baffle should extend across the full width of the wet detention basin and be keyed into the basin side slopes. If the berm embankments are greater than 4 feet in height, the berm should be constructed by excavating a key equal to 50% of the embankment cross-sectional height and width. This requirement may be waived if recommended by a licensed civil engineer for the specific site conditions. The geotechnical investigation must consider the situation in which one of the two cells is empty while the other remains full of water.

- 2) The top of the berm should extend to the permanent pool surface or be one foot below the permanent pool surface to discourage public access. If the top of the berm is at the water permanent pool surface, the side slopes should be 4H:1V. Berm side slopes may be steeper (up to 3:1) if the berm is submerged one foot.
- 3) If good vegetation cover is not established on the berm, erosion control measures should be used to prevent erosion of the berm back-slope when the basin is initially filled.
- 4) The interior berm or baffle may be a retaining wall provided that the design is prepared and stamped by a licensed civil engineer. If a baffle or retaining wall is used, it should be submerged one foot below the permanent pool surface to discourage access by pedestrians.
- 5) Internal earthen berms 6 feet high or less should have a minimum top width 6 feet or as recommended by a civil engineer.

Water Supply

- 1) Water balance calculations should be provided to demonstrate that adequate water supply will be present to maintain a pool of water during a drought year when precipitation is 50% of average for the site. Water balance calculations should include evapotranspiration, infiltration, precipitation, spillway discharge, and dry weather flow (where appropriate).
- 2) Where water balance indicates that losses will exceed inputs, a source of water should be provided to maintain the basin water surface elevation throughout the year. The water supply should be of sufficient quantity and quality to not have an adverse impact on the wet detention basin water quality. Water that meets drinking water standards should be assumed to be of sufficient quality.
- 3) Wet detention basin may be designed as seasonal ponds where the water balance and water supply conditions make it infeasible to sustain a permanent wet detention basin.

Soils Considerations

Wet detention basin implementation in areas with high permeability soils requires liners to increase the chances of maintaining a permanent pool in the basin. Liners can be either synthetic materials or imported lower permeability soils (i.e., clays). The water balance assessment should determine whether a liner is required.

If low permeability soils are used for the liner, a minimum of 18 inches of native soil amended with good topsoil or compost (one part compost mixed with 3 parts native soil) should be placed over the liner. If a synthetic material is used, a soil depth of 2 feet is recommended to prevent damage to the liner during planting.

Buffer Zone

A minimum of 25 feet buffer should be provided around the top perimeter of the wet detention basin. The portion of the access road outside of the maximum water level may be included as part of the buffer.

Stormwater Quality Design Features

- 1) Wet detention basins that are located in publicly-accessible or highly visible locations should include design features that will improve and maintain the quality of water within the BMP at a level suitable for the proposed location and uses of the surrounding area. Typical design features include aeration, pumped circulation, filters, biofilters, and other facilities that operate year-round to remove pollutants and nutrients. Stormwater quality design features will result in higher quality water in the BMP and lower discharges of pollutants downstream.
- 2) Wet detention basins in publicly-accessible or highly visible locations should have a maintenance plan that includes regular collection and removal of trash from the area within and surrounding the BMP.
- 3) If fencing is required for wet detention basins in publicly-accessible or highly visible locations, the fence can be designed to be aesthetically incorporated into the site and Shrubs (approved, California-adapted species) can be used to hide the fencing. See vegetation section below.

Energy Dissipation

- 1) The inlet to the wet detention basin should be submerged with the inlet pipe invert a minimum of two feet from the basin bottom (not including sediment storage). The top of the inlet pipe should be submerged at least 1 foot, if possible. Intent: The inlet is submerged to dissipate energy of the incoming flow. The distance from the bottom is set to minimize resuspension of settled sediments. Alternative inlet designs that accomplish these objectives are acceptable.
- 2) Energy dissipation controls should also be used at the outlet from the wet detention basin unless the basin discharges to a stormwater conveyance system or hardened channel.

Vegetation

A plan should be prepared that indicates how aquatic, temporarily submerged areas (extended detention wet detention basins) and terrestrial areas will be stabilized with vegetation.

- 1) If the second cell of the wet detention basin is 3 feet or shallower, the bottom area should be planted with emergent wetland vegetation.

- 2) Emergent aquatic vegetation should be planted to cover 25-75% of the area of the permanent pool.
- 3) Outside of the basin, native vegetation adapted for site conditions should be used in non-irrigated sites.
- 4) The area surrounding a wet detention basin should be landscaped to minimize erosion and should adhere to the following criteria so as not to hinder maintenance operations:
 - 5) No trees or shrubs may be planted within 15 feet of inlet or outlet pipes or manmade drainage structures such as spillways, flow spreaders, or earthen embankments. Species with roots that seek water, such as willow or poplar, should not be used within 50 feet of pipes or manmade structures. Weeping willow (*Salix babylonica*) should not be planted in or near detention basins.
- 6) Prohibited non-native plant species will not be permitted. For more information on invasive weeds, including biology and control of listed weeds, look at the [encycloweedia](#) located at the California Department of Food and Agriculture website- or the California Invasive Plant Council website at www.cal-ipc.org.
- 7) A landscape professional should provide recommendations on appropriate plants, fertilizer, mulching applications, and irrigation requirements (if any) to ensure healthy vegetation growth.

Outlet Structure

- 1) An outlet pipe and outlet structure should be provided. The outlet pipe may be a perforated standpipe strapped to a manhole or placed in an embankment, suitable for extended detention, or may be back-sloped to a catch basin with a grated opening (jail house window) or manhole with a cone grate (birdcage). The grate or birdcage openings provide an overflow route should the basin outlet pipe become clogged.
- 2) For extended detention wet detention basin, outlet structures should be designed to provide 12 to 48 hour emptying time for the water quality volume above the permanent pool.
- 3) The basin outlet pipe should be sized, at a minimum, to pass flows greater than the stormwater quality design peak flow for off-line basins or flows greater than the peak runoff discharge rate for the 100-year, 24-hr design storm for on-line basins.

Emergency Spillway

An emergency overflow spillway in addition to the primary overflow outlet (as described above) is required. The emergency spillway should be sized for flows greater than the peak 100-year 24-hour storm if the basin is designed on-line or, if the basin is designed off-line, the spillway should be sized for flows greater than the basin design volume (e.g., stormwater quality design volume). The spillway provide for adequate energy dissipation

downstream. The spillway should allow for at least 12 inches of freeboard above the emergency overflow water surface elevation if the basin is on-line. If the basin is -line, 2 feet of freeboard is preferable.

Spillways shall meet the California Department of Water Resources, Division of Safety of Dams Guidelines for the Design and Construction of Small Embankment Dams (<http://damsafety.water.ca.gov/docs/GuidelinesSmallDams.pdf>). *Intent: Emergency overflow spillways are intended to control the location of basin overtopping and safely direct overflows back into the downstream conveyance system or other acceptable discharge point.*

On-line Basins

- 1) On-line basins must have an emergency overflow spillway to prevent overtopping of walls or berms should blockage of the primary outlet occur based on a downstream risk assessment.
- 2) The overflow spillway must be sized to pass flows greater than the design peak runoff discharge rate for the 100-yr, 24-hr storm.
- 3) The minimum freeboard should be 1 foot (but preferably at least 2 feet) above the maximum water surface elevation over the emergency spillway.

Off-line Basins

- 1) Off-line basins must have either an emergency overflow spillway or an emergency overflow riser. The emergency overflow must be designed to pass flows greater than the basin design volume (e.g., stormwater quality design volume) directly to the downstream conveyance system or another acceptable discharge point. Where an emergency overflow spillway would discharge to a steep slope, an emergency overflow riser, in addition to the spillway should be provided. See Appendix E for basin/pond outlet sizing worksheets.
- 2) The emergency overflow spillway should be armored to withstand the energy of the spillway flows. The spillway should be constructed of grouted rip-rap.
- 3) The minimum freeboard should be 1 foot above the maximum water surface elevation over the emergency spillway.

Side Slopes

- 1) Interior side slopes above the stormwater quality design depth and up to the emergency overflow water surface steeper than 4:1 (H:V) should be stabilized to prevent erosion with a method approved by the local permitting authority.
- 2) Exterior side slopes steeper than 2:1 (H:V) should be stabilized to prevent erosion with a method approved by the local permitting authority.

- 3) For any slope (interior or exterior) greater than 2:1 (H:V), a geotechnical investigation and report must be submitted and approved by the local permitting authority.
- 4) Landscaped slopes should be no steeper than 3:1 (H:V) to allow for maintenance.
- 5) Basin walls may be vertical retaining walls, provided: (a) they are constructed of reinforced concrete, (b) a fence is provided along the top of the wall (see fencing below) or further back, and (c) the design is stamped by a licensed civil engineer.

Embankments

- 1) Earthworks and berm embankments should be performed in accordance with the latest edition of the “Greenbook Standard Specifications for Public Works Construction”.
- 2) Embankments are earthen slopes or berms used for detaining or redirecting the flow of water.
- 3) Top of berm should be 2 feet minimum below the stormwater quality design water surface and should be keyed into embankment a minimum of 1 foot on both sides.
- 4) Typically, the top width of berm embankments are at least 20 feet, but narrower embankments may be plausible if approved by the civil engineer and the Local permitting authority.
- 5) Basin berm embankments should be constructed on native consolidated soil (or adequately compacted and stable fill soils analyzed by a licensed civil engineer) free of loose surface soil materials, roots, and other organic debris.
- 6) The berm embankment should be constructed of compacted soil (95% minimum dry density, modified proctor method per ASTM D1557), placed in 6-inch lifts.
- 7) Basin berm embankments greater than 4 feet in height should be constructed by excavating a key equal to 50% of the berm embankment cross-sectional height and width. This requirement may be waived if specifically recommended by a licensed civil engineer.
- 8) The berm embankment should be constructed of compacted soil (95% minimum dry density, modified proctor method per ASTM D1557), placed in 6-inch lifts.
- 9) Low growing native or non-invasive perennial grasses should be planted on downstream embankment slopes. See vegetation section below.

Fencing

Safety is provided either by fencing of the facility or by managing the contours of the basin to eliminate drop-offs and other hazards.

- 1) If fences are required, fences should be designed and constructed in accordance with current and relevant policies and typically are required to be located at or above the overflow water surface elevation. Shrubs (approved, California-adapted species) can be used to hide the fencing. See vegetation section above.

Right-of-Way

- 2) Wet detention basins and associated access roads to be maintained by a public agency should be dedicated in fee or in an easement to the public agency with appropriate access.

Maintenance Access

- 1) Ownership of the basin and maintenance thereof is the responsibility of the developer/applicant. A maintenance agreement is required to ensure adequate performance and allow emergency access to the facilities.
- 2) Maintenance access road(s) should be provided to the control structure and other drainage structures associated with the basin (e.g., inlet, emergency overflow or bypass structures). Manhole and catch basin lids should be in or at the edge of the access road.
- 3) A ramp into the basin should be constructed near the basin outlet. An access ramp is required for removal of sediment with a backhoe or loader and truck. The ramp should extend to the basin bottom to avoid damage to vegetation planted on the basin slope.
- 4) All access ramps and roads should be provided in accordance with the current policies of the Flood Control District.

Vector Control

- 1) A Mosquito Management Plan or Service Contract should be approved or waived by the local Vector Control District for any facility that maintains a pool of water for 72 hours or more.

Operations and Maintenance

General Requirements

Maintenance is of primary importance if extended detention basins are to continue to function as originally designed. A maintenance agreement must be developed with the Flood Control District to ensure adequate performance and allow the County emergency access. Maintenance of the basin is the responsibility of the development, unless otherwise agreed upon.

A specific maintenance plan shall be formulated for each facility outlining the schedule and scope of maintenance operations, as well as the data handling and reporting requirements. The following are general maintenance requirements:

- 1) The basin should be inspected annually and inspections after major storm events are encouraged (see Appendix I for guidance on facility maintenance inspections). Trash and debris should be removed as needed, but at least annually prior to the beginning of the wet season (see Appendix I for dry extended detention basin inspection and maintenance checklist).
- 2) Site vegetation should be maintained as follows:
- 3) Vegetation, large shrubs, or trees that limit access or interfere with basin operation should be pruned or removed.
- 4) Slope areas that have become bare should be revegetated and eroded areas should be regraded prior to being revegetated.
- 5) Grass should be mowed to 4"-9" high and grass clippings should be removed.
- 6) Fallen leaves and debris from deciduous plant foliage should be raked and removed.
- 7) Invasive vegetation, such as Alligatorweed (*Alternanthera philoxeroides*), Halogeton (*Halogeton glomeratus*), Spotted Knapweed (*Centaurea maculosa*), Giant Reed (*Arundo donax*), Castor Bean (*Ricinus communis*), Perennial Pepperweed (*Lepidium latifolium*), and Yellow Starthistle (*Centaurea solstitialis*) should be removed and replaced with non-invasive species. Invasive species should never contribute more than 25% of the vegetated area. For more information on invasive weeds, including biology and control of listed weeds, look at the [encycloweedia](#) located at the California Department of Food and Agriculture website or the California Invasive Plant Council website at www.cal-ipc.org.
- 8) Dead vegetation should be removed if it exceeds 10% of area coverage. Vegetation should be replaced immediately to maintain cover density and control erosion where soils are exposed.
- 9) No herbicides or other chemicals should be used to control vegetation.
- 10) Sediment buildup exceeding 50% of the forebay capacity should be removed. Sediment from the remainder of the basin should be removed when 6 inches of sediment accumulates. Sediments should be tested for toxic substance accumulation in compliance with current disposal requirements if land uses in the catchment include commercial or industrial zones, or if visual or olfactory indications of pollution are noticed. If toxic substances are encountered at concentrations exceeding thresholds of Title 22, Section 66261 of the California Code of Regulations, the sediment must be disposed of in a hazardous waste landfill.

- 11) Following sediment removal activities, replanting, and/or reseeding of vegetation may be required for reestablishment.

Construction Considerations

The use of treated wood or galvanized metal anywhere inside the facility is prohibited. The use of galvanized fencing is permitted if in accordance with the Fencing requirement above.

TCM-3: Constructed Wetland

A constructed treatment wetland is a system consisting of a sediment forebay and one or more permanent micro-pools with aquatic vegetation covering a significant portion of the basin. Constructed treatment wetlands typically include components such as an inlet with energy dissipation, a sediment forebay for settling out coarse solids and to facilitate maintenance, a base with shallow sections (1 to 2 feet deep) planted with emergent vegetation, deeper areas or micro pools (3 to 5 feet deep), and a water quality outlet structure. The interactions between the incoming stormwater runoff, aquatic vegetation, wetland soils, and the associated physical, chemical, and biological unit processes are a fundamental part of constructed treatment wetlands.

Constructed Wetlands

Application

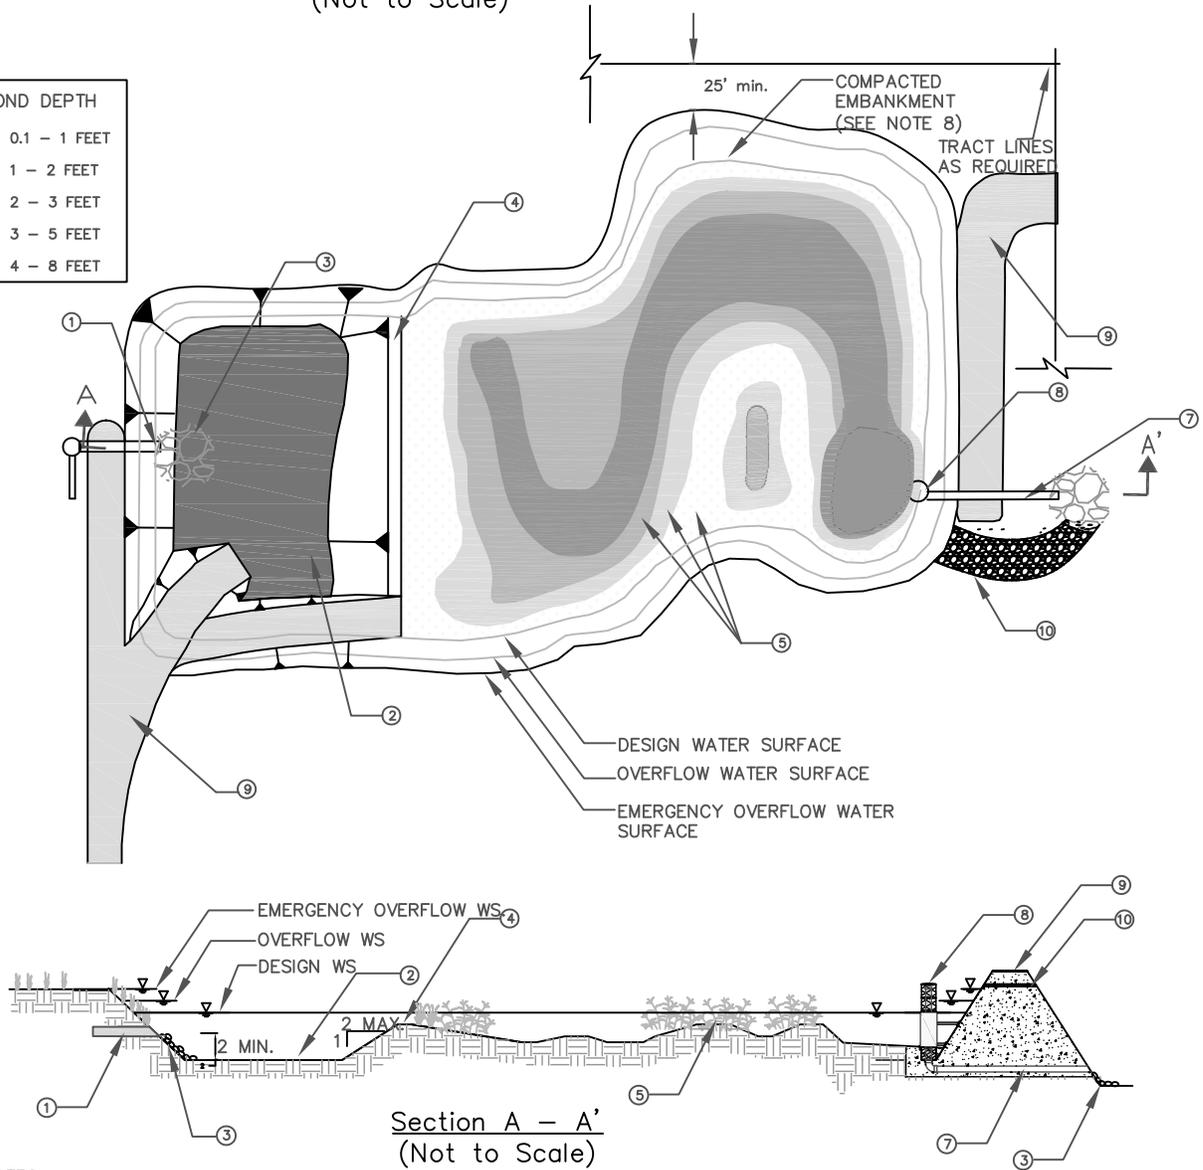

- Regional detention & treatment
- Roads, highways, parking lots, commercial, residential
- Parks, open spaces, and golf courses

Preventative Maintenance

- inspected at a minimum annually and inspections after major storm events
- Pruned or remove vegetation, large shrubs, or trees that limit access or interfere with basin operation
- Remove sediment buildup at inlets and outlets

Plan View
(Not to Scale)

POND DEPTH	
	0.1 – 1 FEET
	1 – 2 FEET
	2 – 3 FEET
	3 – 5 FEET
	4 – 8 FEET

NOTES:

- ① INLET PIPE SHOULD BE SUBMERGED WITH A MINIMUM OF 2' DISTANCE FROM THE BOTTOM
- ② SEDIMENT FOREBAY. FORE BAY VOLUME SHALL EQUAL 10% TO 20% OF TOTAL WETLAND VOLUME. FORE BAY DEPTH SHALL BE 4' MIN TO 8' MAX PLUS AN ADDITIONAL 1' MIN SEDIMENT STORAGE DEPTH.
- ③ RIP RAP APRON OR OTHER INLET ENERGY DISSIPATION.
- ④ BERM AT DESIGN WATER SURFACE ELEVATION OR SUBMERGED 1' BELOW DESIGN WATER SURFACE ELEVATION. EXTEND BERM ACROSS ENTIRE WIDTH OF THE WETLAND.
- ⑤ WETLAND VEGETATION. PLANTING SCHEME MUST BE DESIGNED BY A WETLAND ECOLOGIST.
- ⑥ EMBANKMENT SIDE SLOPES SHALL BE NO STEEPER THAN 2H:1V OUTSIDE AND 3H:1V INSIDE
- ⑦ SIZE OUTLET PIPE TO PASS 100-YEAR PEAK FLOW FOR ONLINE AND WATER QUALITY PEAK FLOW FOR OFFLINE BASINS.
- ⑧ WATER QUALITY OUTLET STRUCTURE. SEE FIGURE 7-2 AND FIGURE 7-3 FOR DETAILS.
- ⑨ MAINTENANCE RAMP SHOULD PROVIDE ACCESS TO BOTH THE FOREBAY AND MAIN BASIN.
- ⑩ INSTALL EMERGENCY OVERFLOW SPILWAY AS NEEDED. SEE FIGURE 2-4 FOR DETAILS

Figure 6-22: Constructed Wetland

Limitations

- In theory, there are no limitations on the tributary area size draining to a constructed treatment wetland; however, constructed treatment wetlands usually require considerable land area. Typically, treatment wetlands capture runoff from tributary areas larger than 10 acres and less than 10 square miles. Smaller “pocket” wetlands can be feasible in areas where space is restricted.
- If the constructed treatment wetland is not used for flow control, the wetland must not interfere with flood control functions of existing conveyance and detention structures.
- Constructed treatment wetlands should not be permitted in areas with site slopes greater than 7% or within 200 feet (on the uphill side) of a steep slope hazard area or a mapped landslide area unless a geotechnical investigation and report is completed by a licensed civil engineer.
- Constructed treatment wetlands require a regular source of water (base flow) to maintain wetland vegetation and associated treatment processes. If adequate base flow is not available year-round, supplemental water may be needed during the summer months to maintain adequate base flow.

Design Criteria

The main challenge associated with constructed treatment wetlands is maintaining base flow to support vegetation. Constructed wetlands should be designed according to the requirements listed in Table 6-25 and outlined in the section below. Constructed wetland BMP sizing worksheets are presented in Appendix E.

Table 6-25: Constructed Wetland Design Criteria

Design Parameter	Unit	Design Criteria
Stormwater quality design volume, SQDV	acre-feet	See Section 2 and Appendix E for calculating SQDV.
Permanent pool volume	%	75% of SQDV
Drawdown time for extended detention (over permanent pool)	hours	48 ; 12 for 50% SQDV (minimum)
Sediment forebay volume	%	30 to 50% of permanent pool surface area
Depth of sediment forebay	feet	2-4 (1 foot of sediment storage required)
Wetland zone volume	%	50-70% of permanent pool surface area
Depth of wetland basin	feet	0.5 to 1.0 (30 to 50% should be 0.5 feet deep)

Design Parameter	Unit	Design Criteria
Wetland (littoral zone) bottom slope	%	10 maximum
Maximum residence time	Days	7 (dry weather)
Freeboard (minimum)	inches	12
Flow path length to width ratio	L:W	2:1, larger preferred
Side slope (maximum)	H:V	4:1 Interior; 3:1 Exterior
Vegetation Type	--	Varies see vegetation section below
Vegetation Height	--	Varies see vegetation section below
Buffer zone (minimum)	feet	25
Minimum outflow device diameter	inches	18

Sizing

In most cases, the constructed treatment wetland permanent pool should be sized to be greater than or equal to the stormwater quality design volume. If extended detention is provided above the permanent pool and the wetland is designed for water quality treatment only, then the permanent pool volume should be a minimum of 80 percent of the stormwater quality design volume and the surcharge volume (above the permanent pool) should make up the remaining 20 percent and provide at least 12 hours of detention. If extended detention is provided and the basin is designed for water quality treatment and peak flow attenuation, then the permanent pool volume should be equal to the water quality treatment volume and the surcharge volume should be sized to attenuate peak flows to meet the peak runoff discharge requirements. The extended detention portion of the wetland above the permanent pool, if provided, functions like a dry extended detention (ED) basin (see [VEG-5: Dry Extended Detention Basin](#)).

Step 1: Calculate the design volume

Constructed wetlands shall be sized to be greater than or equal to the SQDV volume (see [Section 2](#) and Appendix E).

Step 2: Determine the Wetland Location, Wetland Type and Preliminary Geometry Based on Site Constraints

Based on site constraints, determine the wetland geometry and the storage available by developing an elevation-storage relationship for the wetland. The equations provided

below assume a trapezoidal geometry for cell 1 (Forebay) and cell 2, and assumes that the wetland does not have extended detention.

- 1) Calculate the width of the wetland footprint, W_{tot} , as follows:

$$W_{tot} = \frac{A_{tot}}{L_{tot}} \quad (\text{Equation 6-81})$$

Where:

A_{tot} = total surface area of the wetland footprint (ft²)

L_{tot} = total length of the wetland footprint (ft)

- 2) Calculate the length of the water quality volume surface area including the internal berm but excluding the freeboard, L_{wq-tot} :

$$L_{wq-tot} = L_{tot} - 2Zd_{fb} \quad (\text{Equation 6-82})$$

Where:

Z = interior side slope as length per unit height

d_{fb} = freeboard depth

- 3) Calculate the width of the water quality volume surface area including the internal berm but excluding freeboard, W_{wq-tot} :

$$W_{wq-tot} = W_{tot} - 2Zd_{fb} \quad (\text{Equation 6-83})$$

- 4) Calculate the total water quality volume surface area including the internal berm and excluding freeboard, A_{wq-tot} :

$$A_{wq-tot} = L_{wq-tot} \times W_{wq-tot} \quad (\text{Equation 6-84})$$

- 5) Calculate the area of the berm, A_{berm} :

$$A_{berm} = W_{berm} \times L_{berm} \quad (\text{Equation 6-85})$$

Where:

W_{berm} = width of the internal berm

L_{berm} = length of the internal berm

- 6) Calculate the water quality surface area excluding the internal berm and freeboard, A_{wq} :

$$A_{wq} = A_{wq = tot} - A_{berm} \quad (\text{Equation 6-86})$$

Step 3: Determine Dimensions of Forebay

30-50% of the SQDV is required to be within the active volume of forebay.

- 1) Calculate the active volume of forebay, V_1 :

$$V_1 = \frac{SQDV \times \%V_1}{100} \quad (\text{Equation 6-87})$$

Where:

$$\%V_1 = \text{percent of SQDV in forebay (\%)}$$

- 2) Calculate the surface area for the active volume of forebay, A_1 :

$$A_1 = \frac{V_1}{d_1} \quad (\text{Equation 6-88})$$

Where:

$$d_1 = \text{average depth for the active volume of forebay (2 -4 ft)} \\ (\text{ft})$$

- 3) Calculate the length of forebay, L_1 . Note, inlet and outlet should be configured to maximize the residence time.

$$L_1 = \frac{A_1}{W_1} \quad (\text{Equation 6-89})$$

Where:

$$W_1 = \text{width of forebay (ft), } W_1 = W_{av-tot} = L_{berm}$$

Step 4: Determine Dimensions of Cell 2

Cell 2 will consist of the remainder of the basin's active volume.

- 1) Calculate the active volume of Cell 2, V_2 :

$$V_2 = SQDV - V_1 \quad (\text{Equation 6-90})$$

- 2) Calculate the surface area of Cell 2, A_2 :

$$A_2 = A_{wq} - A_1 \quad (\text{Equation 6-91})$$

- 3) Calculate the top length of Cell 2, L_2 :

$$L_2 = \frac{A_2}{W_2} \quad (\text{Equation 6-92})$$

Where:

$$W_2 = \text{width of Cell 2 (ft), } W_2 = W_1 = W_{\text{wq-tot}} = L_{\text{berm}}$$

- 4) Verify that the length-to-width ratio of Cell 2, LW_2 , is at least 3:1 with $\geq 4:1$ preferred. If the length-to-width ratio is less than 3:1, modify input parameters until a ratio of at least 3:1 is achieved. If the input parameters cannot be modified as a result of site constraints, another site for the pond should be chosen.

$$LW_2 = \frac{L_2}{W_2} \quad (\text{Equation 6-93})$$

- 5) Calculate the very shallow zone surface area, A_{vs} :

$$A_{vs} = \frac{A_2 \cdot \% A_{vs}}{100} \quad (\text{Equation 6-94})$$

Where:

$$\%A_{vs} = \text{percent of surface area of very shallow zone}$$

- 6) Calculate the volume of the shallow zone, V_{vs} :

$$V_{vs} = A_{vs} \cdot d_{vs} \quad (\text{Equation 6-95})$$

Where:

$$d_{vs} = \text{average depth of the very shallow zone (0.1 - 1 ft)}$$

- 7) Calculate the length of the very shallow zone, L_{vs} :

$$L_{vs} = \frac{A_{vs}}{W_{vs}} \quad (\text{Equation 6-96})$$

Where:

$$W_{vs} = \text{width of the very shallow zone (ft), } W_{vs} = W_2$$

- 8) Calculate the surface area of the shallow zone, A_s :

$$A_s = \frac{A_2 \cdot \% A_s}{100} \quad (\text{Equation 6-97})$$

Where:

$\%A_s$ = percent of surface area of shallow zone

9) Calculate the volume of the shallow zone, V_s :

$$V_s = A_s \cdot d_s \quad (\text{Equation 6-98})$$

Where:

d_s = average depth of shallow zone (1 - 3 ft)

10) Calculate length of the shallow zone, L_s :

$$L_s = \frac{A_s}{W_s} \quad (\text{Equation 6-99})$$

Where:

W_s = width of the shallow zone (ft), $W_s = W_2$

11) Calculate the surface area of the deep zone, A_{deep} :

$$A_{deep} = A_2 - A_{vs} - A_s \quad (\text{Equation 6-100})$$

12) Calculate the volume of the deep zone, V_{deep} :

$$V_{deep} = V_2 - V_{vs} - V_s \quad (\text{Equation 6-101})$$

13) Calculate the average depth of the deep zone (3-5 ft), d_{deep} :

$$d_{deep} = \frac{V_{deep}}{A_{deep}} \quad (\text{Equation 6-102})$$

14) Calculate length of the deep zone, L_{deep} :

$$L_{deep} = \frac{A_{deep}}{W_{deep}} \quad (\text{Equation 6-103})$$

Where:

W_{deep} = width of the deep zone (ft), $W_{deep} = W_2$

Step 5: Ensure design requirements and site constraints are achieved

Check design requirements and site constraints. Modify design geometry until requirements are met. If the chosen site for the basin is inadequate to meet the design requirements, choose a new location or alternative treatment BMP.

Step 6: Size Outlet Structure

For wetlands with detention, the outlet structures should be designed to provide 12 hours emptying time for the water quality volume or the required detention necessary for achieving the peak runoff discharge requirements if the extended detention is designed for flow attenuation.

The wetland outlet pipe should be sized, at a minimum, to pass flows greater than the stormwater quality design peak flow for on-line basins or flows greater than the peak runoff discharge rate for the 100-year, 24-hr design storm for on-line basins.

Step 7: Determine Emergency Spillway Requirements

For online basins, an emergency overflow spillway should be sized to pass flows greater than the design peak runoff discharge rate for the 100-yr, 24-hr storm in order to prevent overtopping of the walls or berms in the event that a blockage of the riser occurs. For offline basins, an emergency spillway or riser should be sized to pass the 100-yr, 24-hr post-development peak storm water runoff discharge rate directly to the downstream conveyance system or another acceptable discharge point. For sites where the emergency spillway discharges to a steep slope, an emergency overflow riser, in addition to the spillway should be provided.

Sizing and Geometry

In most cases, the constructed treatment wetland permanent pool should be sized to be greater than or equal to the stormwater quality design volume. If extended detention is provided above the permanent pool and the wetland is designed for water quality treatment only, then the permanent pool volume should be a minimum of 80 percent of the stormwater quality design volume and the surcharge volume (above the permanent pool) should make up the remaining 20 percent and provide at least 12 hours of detention. If extended detention is provided and the basin is designed for water quality treatment and peak flow attenuation, then the permanent pool volume should be equal to the water quality treatment volume and the surcharge volume should be sized to attenuate peak flows to meet the peak runoff discharge requirements. A constructed treatment wetland design worksheets are presented in Appendix E. The extended detention portion of the wetland above the permanent pool, if provided, functions like a dry extended detention (ED) basin (see [TCM-1: Dry Extended Detention Basin](#)).

- 1) Constructed treatment wetlands should consist of at least two cells including a sediment forebay and a wetland basin.
- 2) The sediment forebay must contain between 10 and 20 percent of the total basin volume.
- 3) The depth of the sediment forebay should be between 4 and 8 feet.
- 4) One foot of sediment storage should be provided in the sediment forebay.

- 5) The “berm” separating the two basins should be uniform in cross-section and shaped such that its downstream side gradually slopes to the main wetland basin.
- 6) The top of berm should be either at the stormwater quality design water surface or submerged 1 foot below the stormwater quality design water surface, as with wet retention basins. Correspondingly, the side slopes of the berm should meet the following criteria:
 - a. If the type of the berm is at the stormwater quality design water surface, the berm side slopes should be no steeper than 4H:1V.
 - b. If the top of berm is submerged 1 foot, the upstream side slope may be a max of 3H:1V.
- 7) The constructed treatment wetlands should be designed with a “naturalistic” shape and a range of depths intermixed throughout the wetland basin to a maximum of 5 feet.

Depth Range (feet)	Percent by Area
0.1 to 1	15
1 to 3	55
3 to 5	30

- 8) The flowpath length-to-width ratio should be a minimum of 2:1, but preferably at least 4:1 or greater. *Intent: a high flow path length to width ratio will maximize fine sediment removal.*
- 9) The minimum freeboard should be 1 foot above the maximum water surface elevation for on-line basins (2 feet preferable) and 1 foot above the maximum water surface elevation for on-line basins.
- 10) Wetland pools should be designed such that the residence time for dry weather flows is no greater than 7 days. *Intent: Minimize vector and stagnation issues.*

Water Supply

Water balance calculations should be provided to demonstrate that adequate water supply will be present to maintain a permanent pool of water during a drought year when precipitation is 50% of average for the site. Water balance calculations should include evapotranspiration, infiltration, precipitation, spillway discharge, and dry weather flow (where appropriate).

Where water balance indicates that losses will exceed inputs, a source of water should be provided to maintain the wetland water surface elevation throughout the year. The water supply should be of sufficient quantity and quality to not have an adverse impact on the

wetland water quality. Water that meets drinking water standards should be assumed to be of sufficient quality.

Soils Considerations

- 1) Implementation of constructed treatment wetlands in areas with high permeability soils (>0.1 in/hr) requires liners to increase the chances of maintaining permanent pools and/or micro-pools in the basin. Liners can be either synthetic materials or imported lower permeability soils (i.e., clays). The water balance assessment should determine whether a liner is required. The following conditions can be used as a guideline.
- 2) The wetland basin should retain water for at least 10 months of the year.
- 3) The sediment forebay should retain at least 3 feet of water year-round.
- 4) Many wetland plants can adapt to periods of summer drought, so a limited drought period is allowed in the wetland basin. This may allow for a soil liner rather than a geosynthetic liner. The sediment forebay should retain water year-round for presettling to be effective.
- 5) If low permeability soils are used for the liner, a minimum of 18 inches of native soil amended with good topsoil or compost (one part compost mixed with 3 parts native soil) should be placed over the liner (see soil amendment Section 5.10). If a synthetic material is used, a soil depth of 2 feet is recommended to prevent damage to the liner during planting.

Buffer Zone

A minimum of 25 feet buffer should be provided around the top perimeter of the constructed treatment wetlands.

Energy Dissipation

- 1) The inlet to the constructed treatment wetland should be submerged with the inlet pipe invert a minimum of two feet from the cell bottom (not including sediment storage). The top of the inlet pipe should be submerged at least 1 foot, if possible. *Intent: the inlet is submerged to dissipate energy of the incoming flow. The distance from the bottom is set to minimize resuspension of settled sediments. Alternative inlet designs that accomplish these objectives are acceptable.*
- 2) Energy dissipation controls must also be used at the outlet/spillway from the constructed treatment wetlands unless the wetland discharges to a stormwater conveyance system or hardened channel.

Vegetation

- 1) The wetland cell(s) should be planted with emergent wetland plants following the recommendations of a wetlands specialist.
- 2) Landscaping outside of the basin is required for all constructed wetlands and should adhere to the following criteria so as not to hinder maintenance operations:
 - a. No trees or shrubs may be planted within 15 feet of inlet or outlet pipes or manmade drainage structures such as spillways, flow spreaders, or earthen embankments. Species with roots that seek water, such as willow or poplar, should not be used within 50 feet of pipes or manmade structures. Weeping willow (*Salix babylonica*) should not be planted in or near detention basins.
 - b. Prohibited non-native plant species will not be permitted. For more information on invasive weeds, including biology and control of listed weeds, look at the [encycloweedia](#) located at the California Department of Food and Agriculture website or the California Invasive Plant Council website at www.cal-ipc.org.
- 3) Project-specific planting recommendations should be provided by a wetland ecologist or a qualified landscape professional including recommendations on appropriate plants, fertilizer, mulching applications, and irrigation requirements (if any) to ensure healthy vegetation growth.

Outlet Structure

An outlet pipe and outlet structure should be provided. The outlet pipe may be a perforated standpipe strapped to a manhole or placed in an embankment, suitable for extended detention, or may be back-sloped to a catch basin with a grated opening (jail house window) or manhole with a cone grate (birdcage). The grate or birdcage openings provide an overflow route should the basin outlet pipe become clogged. The outlet should be protected from clogging by a skimmer shield that starts at the bottom of the permanent pool and extends above the SQDV depth. A trash rack is also required.

For wetlands with detention, the outlet structures should be designed to provide 12 hours emptying time for the water quality volume or the required detention necessary for achieving the peak runoff discharge requirements if the extended detention is designed for flow attenuation.

The wetland outlet pipe should be sized, at a minimum, to pass flows greater than the stormwater quality design peak flow for on-line basins or flows greater than the peak runoff discharge rate for the 100-year, 24-hr design storm for on-line basins.

See the dry extended detention section (see [ST-1: Dry Extended Detention Basin](#)) and Appendix E for further detail on outlet sizing.

Emergency Spillway

An emergency overflow spillway in addition to the primary overflow outlet (as described above) is required. The emergency spillway should be sized for flows greater than the peak 100-year 24-hour storm if the basin is designed on-line or, if the basin is designed on-line, the spillway should be sized for flows greater than the basin design volume (e.g., stormwater quality design volume). The spillway provide for adequate energy dissipation downstream. The spillway should allow for at least 12 inches of freeboard above the emergency overflow water surface elevation if the basin is on-line. If the basin is on-line, 2 feet of freeboard is preferable.

Spillways shall meet the California Department of Water Resources, Division of Safety of Dams Guidelines for the Design and Construction of Small Embankment Dams (<http://damsafety.water.ca.gov/docs/GuidelinesSmallDams.pdf>). *Intent: Emergency overflow spillways are intended to control the location of basin overtopping and safely direct overflows back into the downstream conveyance system or other acceptable discharge point.*

On-line Basins

- 1) On-line basins must have an emergency overflow spillway to prevent overtopping of walls or berms should blockage of the primary outlet occur based on a downstream risk assessment.
- 2) The overflow spillway must be sized to pass flows greater than the design peak runoff discharge rate for the 100-yr, 24-hr storm.
- 3) The minimum freeboard should be 1 foot (but preferably at least 2 feet) above the maximum water surface elevation over the emergency spillway.

Off-line Basins

- 1) Off-line basins must have either an emergency overflow spillway or an emergency overflow riser. The emergency overflow must be designed to pass the 100-yr 24-hr post-development peak stormwater runoff discharge rate (see Appendix E for further detail) directly to the downstream conveyance system or another acceptable discharge point. Where an emergency overflow spillway would discharge to a steep slope, an emergency overflow riser, *in addition* to the spillway should be provided.
- 2) The emergency overflow spillway should be armored to withstand the energy of the spillway flows. The spillway should be constructed of grouted rip-rap.
- 3) The minimum freeboard should be 1 foot above the maximum water surface elevation over the emergency spillway.

Side Slopes

- 1) Interior side slopes above the stormwater quality design depth and up to the emergency overflow water surface steeper than 4:1 (H:V) should be stabilized to prevent erosion with a method approved by the local permitting authority.
- 2) Exterior side slopes steeper than 2:1 (H:V) should be stabilized to prevent erosion with a method approved by the local permitting authority.
- 3) For any slope (interior or exterior) greater than 2:1 (H:V), a geotechnical investigation and report must be submitted and approved by the local permitting authority.
- 4) Landscaped slopes should be no steeper than 3:1 (H:V) to allow for maintenance.
- 5) Basin walls may be vertical retaining walls, provided: (a) they are constructed of reinforced concrete, (b) a fence is provided along the top of the wall (see fencing below) or further back, and (c) the design is stamped by a licensed civil engineer and approved by the local permitting authority.

Embankments

- 1) Earthworks and berm embankments should be performed in accordance with the latest edition of the “Greenbook Standard Specifications for Public Works Construction”.
- 2) Embankments are earthen slopes or berms used for detaining or redirecting the flow of water.
- 3) Top of berm should be 2 feet minimum below the stormwater quality design water surface and should be keyed into embankment a minimum of 1 foot on both sides.
- 4) Typically, the top width of berm embankments are at least 20 feet, but narrower embankments may be plausible if approved by the civil engineer and the local permitting authority.
- 5) Basin berm embankments should be constructed on native consolidated soil (or adequately compacted and stable fill soils analyzed by a licensed civil engineer) free of loose surface soil materials, roots, and other organic debris.
- 6) Basin berm embankments greater than 4 feet in height should be constructed by excavating a key equal to 50% of the berm embankment cross-sectional height and width. This requirement may be waived if specifically recommended by a licensed civil engineer.
- 7) The berm embankment should be constructed of compacted soil (95% minimum dry density, modified proctor method per ASTM D1557), placed in 6-inch lifts.

- 8) Low growing native or non-invasive perennial grasses should be planted on downstream embankment slopes. See vegetation section below.

Fencing

Safety is provided either by fencing of the facility or by managing the contours of the basin to eliminate drop-offs and other hazards.

- 1) Provide fencing in accordance with the local permitting agency's requirements. Perimeter fencing (minimum height of 42 inches) should be required on all basins exceeding two feet in depth or where interior side slopes are steeper than 6:1 (H:V).
- 2) If fences are required, fences should be designed and constructed in accordance with current policies of the local permitting agency and should be located at or above the overflow water surface elevation. Shrubs (approved, California-adapted species) can be used to hide the fencing. See vegetation section above.

Right-of-Way

- 1) Constructed treatment wetlands and associated access roads to be maintained by a public agency should be dedicated in fee or in an easement to the public agency with appropriate access.

Maintenance Access

- 1) Ownership of the basin and maintenance thereof is the responsibility of the developer/applicant. A maintenance agreement is required to ensure adequate performance and allow emergency access to the facilities.
- 2) Maintenance access road(s) should be provided to the control structure and other drainage structures associated with the basin (e.g., inlet, emergency overflow or bypass structures). Manhole and catch basin lids should be in or at the edge of the access road.
- 3) An access ramp into the basin should be constructed near the basin outlet. An access ramp is required for removal of sediment with a backhoe or loader and truck. The ramp should extend to the basin bottom to avoid damage to vegetation planted on the basin slope.
- 4) All access ramps and roads should be provided in accordance with the current policies of the Flood Control District.

Vector Control

- 1) A Mosquito Management Plan or Service Contract should be approved or waived by the local Vector Control District for any facility that maintains a pool of water for 72 hours or more.

Construction Considerations

The use of treated wood or galvanized metal anywhere inside the facility is prohibited. The use of galvanized fencing is permitted if in accordance with the Fencing requirement above.

Operations and Maintenance

Maintenance is of primary importance if constructed treatment wetlands basins are to continue to function as originally designed. A specific maintenance plan shall be formulated for each facility outlining the schedule and scope of maintenance operations, as well as the data handling and reporting requirements. The following are general maintenance requirements:

- 1) The constructed treatment wetlands basin should be inspected twice annually or more frequently, and inspections after major storm events are encouraged (see Appendix I for a constructed treatment wetland inspection and maintenance checklist). Trash and debris should be removed as needed, but at least annually prior to the beginning of the wet season.
- 2) Site vegetation should be maintained as frequently as necessary to maintain the aesthetic appearance of the site and to prevent clogging of outlets, creation of dead volumes, and barriers to mosquito fish to access pooled areas, and as follows:
- 3) Vegetation, large shrubs, or trees that limit access or interfere with basin operation should be pruned or removed.
- 4) Slope areas that have become bare should be revegetated and eroded areas should be regraded prior to being revegetated.
- 5) Invasive vegetation, such as Alligatorweed (*Alternanthera philoxeroides*), Halogeton (*Halogeton glomeratus*), Spotted Knapweed (*Centaurea maculosa*), Giant Reed (*Arundo donax*), Castor Bean (*Ricinus communis*), Perennial Pepperweed (*Lepidium latifolium*), and Yellow Starthistle (*Centaurea solstitialis*) should be removed and replaced with non-invasive species. Invasive species should never contribute more than 25% of the vegetated area. For more information on invasive weeds, including biology and control of listed weeds, look at the [encyclopededia](#) located at the California Department of Food and Agriculture website or the California Invasive Plant Council website at www.cal-ipc.org.
- 6) Dead vegetation should be removed if it exceeds 10% of area coverage. This does not include seasonal die-back where roots would grow back later in colder areas. Vegetation should be replaced immediately to maintain cover density and control erosion where soils are exposed.
- 7) Sediment buildup exceeding 6 inches over the storage capacity in the first cell should be removed. Sediments should be tested for toxic substance accumulation in compliance with current disposal requirements if land uses in the catchment include

commercial or industrial zones, or if visual or olfactory indications of pollution are noticed. If toxic substances are encountered at concentrations exceeding thresholds of Title 22, Section 66261 of the California Code of Regulations, the sediment must be disposed of in a hazardous waste landfill. Clean forebay every two years at a minimum, to avoid accumulation in main wetland area. Environmental regulations and permits may be involved with the removal of wetland deposits. When the main wetland area needs to be cleaned, it is suggested that the main area be cleaned one half at a time with at least one growing season in between cleanings. This will help to preserve the vegetation and enable the wetland to recover more quickly from the cleaning.

- 8) Repair erosion to banks and bottom as required.
- 9) Inspect outlet for clogging a minimum of twice a year, before and after the rainy season, after large storms, and more frequently if needed. Correct observed problems as necessary.
- 10) Following sediment removal activities, replanting, and/or reseeding of vegetation may be required for reestablishment.

TCM-4: Sand Filters

Sand filters operate much like bioretention facilities; however, instead of filtering stormwater through engineered soils, stormwater is filtered through a constructed sand bed with an underdrain system. Runoff enters the filter and spreads over the surface. As flows increase, water backs up on the surface of the filter where it is held until it can percolate through the sand. The treatment pathway is vertical (downward through the sand) to a perforated underdrain system that is connected to the downstream storm drainage system or to an infiltration facility. As stormwater passes through the sand, pollutants are trapped in the small pore spaces between sand grains or are adsorbed to the sand surface.

Application

- Adjacent to parking lots
- Road medians and shoulders
- Within open areas or play fields

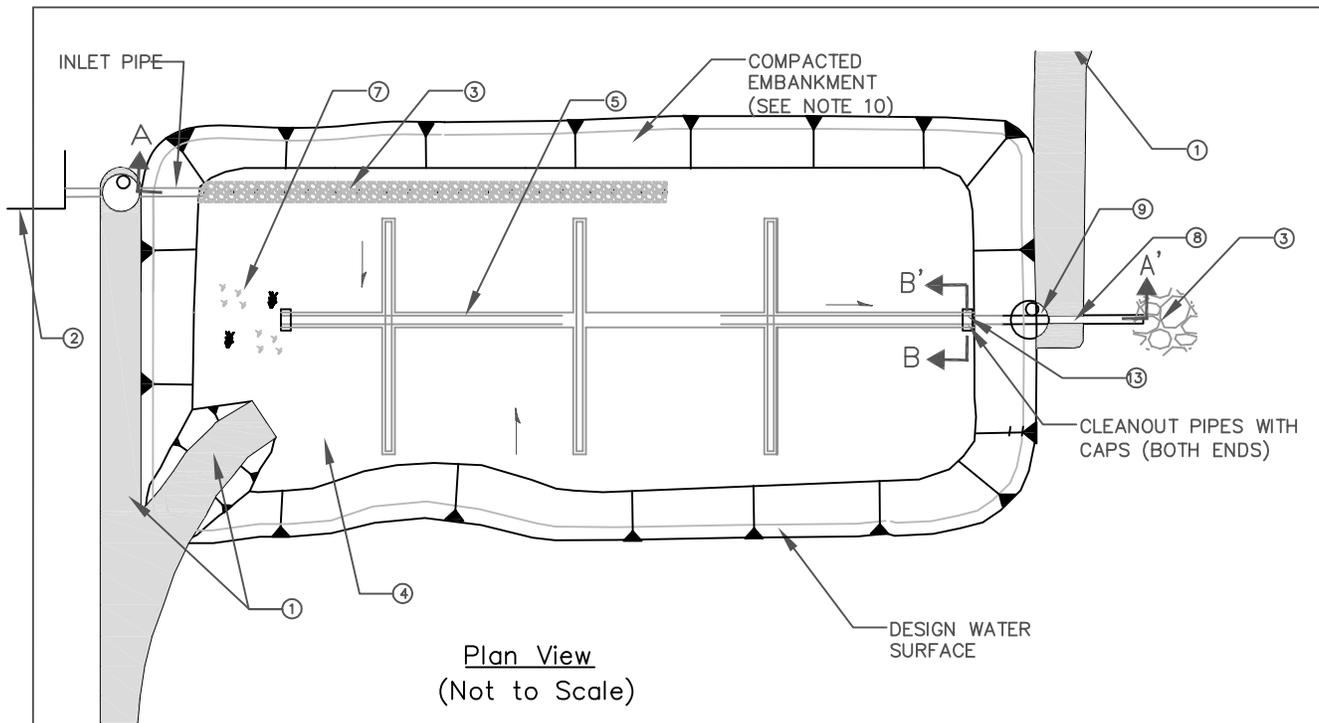

Preventative Maintenance

- Remove trash and debris, minor sediment accumulation, and obstructions near inlet and outlet structures
- Replace top 2” – 4” of sand
- Mow or weed surface of filter

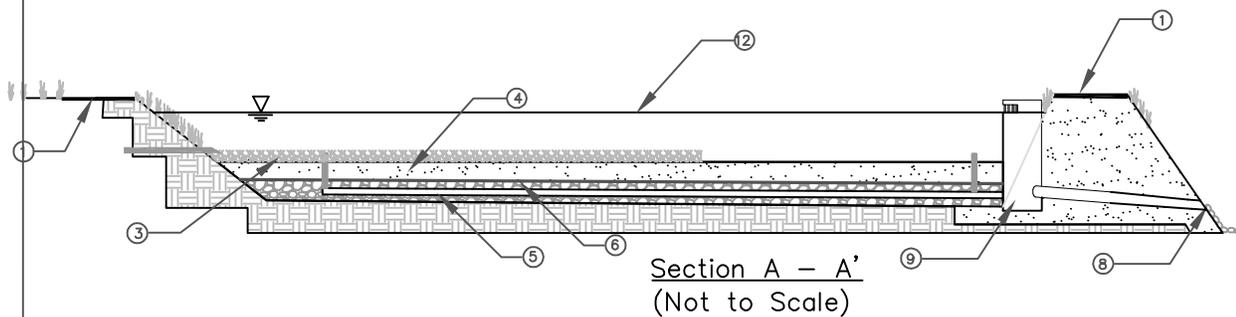

Sand filters connected to impervious surfaces

Section A - A'
(Not to Scale)

NOTES:

- ① INSTALL MAINTENANCE ACCESS ROAD AND RAMP TO BOTTOM OF SAND FILTER.
- ② UPSTREAM PRETREATMENT SHALL BE PROVIDED. IN THE ABSENCE OF PRETREATMENT, INCLUDE SEDIMENT FOREBAY WITH VOLUME EQUAL TO 10-20% OF TOTAL SAND FILTER VOLUME.
- ③ FLOW SPREADER TO EVENLY DISTRIBUTE FLOWS ALONG AT LEAST 20% OF PERIMETER.
- ④ FILTER BED SHALL BE A 24" MINIMUM SAND LAYER ON TOP OF 8" MINIMUM GRAVEL OR DRAIN ROCK BACKFILL.
- ⑤ 6" MINIMUM DIAMETER PERFORATED PIPE UNDERDRAIN SURROUNDED BY GRAVEL BEDDING. INSTALL AT 0.5% MINIMUM SLOPE
- ⑥ INSTALL GEOTEXTILE FABRIC OVERLAIN BY 1" OF DRAIN ROCK OR TRANSITIONALLY GRADED AGGREGATE BETWEEN SAND AND GRAVEL LAYER.
- ⑦ VEGETATION MAY BE PLANTED ON TOP OF FILTER BED. NO TOP SOIL SHALL BE ADDED TO FILTER BED.
- ⑧ SIZE OUTLET PIPE STRUCTURE TO PASS WATER QUALITY DESIGN STORM AND INCLUDE AN EMERGENCY OVERTFLOW.
- ⑨ EMERGENCY OVERTFLOW STRUCTURE.
- ⑩ ¾" - 1½" WASHED DRAIN ROCK OR GRAVEL LAYER.
- ⑪ DESIGN WATER SURFACE. 6' MAX PONDING DEPTH.

Figure 6-23: Sand Filter

Limitations

Limitations for sand filters include:

- The sand filter should be located away from trees producing leaf litter or areas contributing significant eroded sediment to prevent clogging.
- Sand filters are should not be used in areas where heavy sediment loads are expected or in tributary areas that are not fully stabilized; high sediment loading rates may cause premature clogging of the filter. Pretreatment is essential.
- Site must have adequate relief between land surface and stormwater conveyance system to permit vertical percolation through the sand filter and collection and conveyance in the underdrain to stormwater conveyance system; four feet of elevation difference is recommended between the inlet and outlet of the filter.
- Not applicable in areas of high groundwater.
- Does not provide quantity control.

Design Criteria

The main challenge associated with sand filters is maintaining the filtration capacity, which is critical to the performance of this BMP. If flows entering the sand filter have high sediment concentrations, clogging of the sand filter is likely. Contribution of eroded soils or leaf litter may also reduce the infiltration and associated treatment capacity of the structure. Sand filters should be designed according to the requirements listed in Table 6-26 and outlined in the section below. BMP sizing worksheets are presented in Appendix E.

Table 6-26: Sand Filter Design Criteria

Design Parameter	Unit	Design Criteria
Stormwater quality design volume, SQDV	acre-feet	See Section 2 and Appendix E for calculating SQDV.
Max depth at SQDV	feet	3
Freeboard (minimum)	feet	1
Length to width ratio	L:W	2:1 (larger preferred)
Filter bed depth	inches	18 inches sand; 9 inches gravel
Max ponding depth above filter bed	feet	6
Drawdown time	Hours	?

Design Parameter	Unit	Design Criteria
Hydraulic conductivity of sand, k	in/hr	1 (equal to 2 ft/day)
Underdrains		6 inch minimum diameter; 0.5% minimum slope
Side slopes	H:V	4:1 (H:V) interior and 3:1 (H:V) exterior, unless stabilization has been approved by a licensed geotechnical engineer; or vertical concrete walls

Pretreatment

Pretreatment must be provided for sand filters in order to reduce the sediment load entering the filter. Pretreatment refers to design features that provide settling of large particles before runoff reaches the filter, easing the long-term maintenance burden. To ensure that pretreatment mechanisms are effective, designers shall incorporate pretreatment such as a biofiltration BMP, proprietary device, or sedimentation forebay. BMPs that are described in the 2011 TGM that may serve this purpose include:

For design specification of selected pre-treatment devices, refer to:

- [VEG-3: Vegetated swale](#)
- [VEG-4: Vegetated filter strip](#)
- [PROP-1: Hydrodynamic separation device](#)

Sizing Criteria

Background

Sand filter design is based on Darcy's law:

$$Q = KiA \quad \text{(Equation 6-104)}$$

Where:

Q = water quality design flow (cfs)

K = hydraulic conductivity (fps)

A = surface area perpendicular to the direction of flow (ft²)

i = hydraulic gradient (ft/ft) for a constant head and constant media depth, computed as follows:

$$i = \frac{h+l}{l} \quad \text{(Equation 6-105)}$$

Where:

h = average depth of water above the filter (ft), defined for this design as $d/2$

d = maximum storage depth above the filter (ft)

l = thickness of sand media (ft)

Darcy's law underlies both the simple and the routing methods of design. The filtration rate V , or more correctly, $1/V$, is the direct input in the sand filter design. The relationship between the filtration rate V and hydraulic conductivity K is revealed by equating Darcy's law and the equation of continuity, $Q = VA$. Specifically:

$$Q = KiA \quad \text{and} \quad Q = VA$$

$$\text{So,} \quad VA = KiA$$

$$\text{Or:} \quad V = Ki \quad \text{(Equation 6-106)}$$

Where,

$$V = \text{filtration rate (ft/s)}$$

Note that $V \neq K$. That is, the filtration rate is not the same as the hydraulic conductivity, but they do have the same units (distance per time). K can be equated to V by dividing V by the hydraulic gradient i , which is defined above.

The hydraulic conductivity K does not change with head nor is it dependent on the thickness of the media, only on the characteristics of the media and the fluid. A design hydraulic conductivity of 1 inch per hour (2 feet per day) used in this simple sizing method is based on bench-scale tests of conditioned rather than clean sand (KCSWDM, 2005) and represents the average sand bed condition as silt is captured and held in the sand bed.

Unlike the hydraulic conductivity, the filtration rate V changes with head and media thickness, although the media thickness is constant in the sand filter design.

Simple Sizing Method

The simple sizing method does not route flows through the filter. It determines the size of the filter based on the simple assumption that inflow is immediately discharged through the filter as if there were no storage volume. An adjustment factor (0.7) is applied to compensate for the greater filter size resulting from this method. Even with the adjustment factor, the simple method generally produces a larger filter size than the routing method.

Step 1: Determine the water quality design volume

Sand filters should be sized to capture and treat the stormwater quality design volume (see [Section E.1](#)).

Step 2: Determine maximum storage depth of water

Determine the maximum water storage depth (d) above the sand filter. This depth is defined as the depth at which water begins to overflow the reservoir pond, and it depends on the site topography and hydraulic constraints. The depth is chosen by the designer, but should be 6 feet or less.

Step 3: Calculate the sand filter area

Determine the sand filter area using the following equation:

$$A_{sf} = \frac{V_{wq}RL}{Kt(h+L)} \quad \text{(Equation 6-107)}$$

Where,

A_{sf}	=	surface area of the sand filter bed (ft ²)
V_{wq}	=	water quality design volume (ft ³)
R	=	routing adjustment factor (use $R = 0.7$)
L	=	sand bed depth (ft)
K_{des}	=	design hydraulic conductivity of media (use 2 ft/day)
t	=	drawdown time (use 1 day)
h	=	average depth of water above the filter (ft), [use ($d/2$) with d from Step 2]

Routing Method

A continuous runoff model, such as US EPA's Stormwater Management Model (SWMM) Model, can be used to optimally size a sand filter. A continuous simulation model consists of three components: a representative long term period of rainfall data (\approx 20 years or greater) as the primary model input; a model component representing the tributary area to the sand filter that takes into account the amount of impervious area, soil types of the pervious area, vegetation, evapotranspiration, etc.; and a component that simulates the sand filter. Using this method, the filter should be sized to capture and treat the WQ design volume from the post-development tributary area.

The continuous simulation model routes predicted tributary runoff to the sand filter, where treatment is simulated as a function of the infiltrative (flow) capacity of the sand filter and the available storage volume above the sand filter. In a continuous runoff model such as SWMM, the physical parameters of the sand filter are represented with stage-storage-discharge relationships. Due to the computational power of ordinary desktop computers, long-term continuous simulations generally take only minutes to run. This allows the modeler to run several simulations for a range of sand filter sizes, varying either the surface area of the filter (and resulting flow capacity) or the storage capacity above the sand filter, or both. Sufficient continuous model simulations should be completed so that results encompass the WQ design volume capture goal.

Model results should be plotted for both varying storage depths above the filter and for varying filter surface area (and resulting flow capacity) while keeping all other parameters constant. The resulting relationship of percent capture as a function of sand filter flow and storage capacity can be used to optimally size a sand filter based on site conditions and restraints.

In addition to continuous simulation modeling, routing spreadsheets and/or other forms of routing modeling that incorporate rainfall-runoff relationships and infiltrative (flow) capacities of sand filters may be used to size facilities. Alternative sizing methodologies should be prepared with good engineering practices.

Sizing and Geometry

- 1) Sand filters shall be sized to capture and filter the Stormwater quality design volume, SQDV (See Section 2 and Appendix E for further detail).
- 2) Sand filters may be designed in any geometric configuration, but rectangular with a 2:1 length-to-width ratio or greater is preferred.
- 3) Filter bed depth must be at least 24 inches, but 36 inches is preferred.
- 4) Depth of water storage over the filter bed should be 6 feet maximum. Minimum freeboard is one foot.
- 5) Sand filters should be placed off-line to prevent scouring of the filter bed by high flows. The overflow structure must be designed to pass the stormwater quality design storm.

Sand Specification

Ideally the effective diameter of the sand, d_{10} (the diameter corresponding to the sieve size that passes 10% of sand grains), should be just small enough to ensure a good quality effluent while preventing penetration of stormwater particles to such a depth that they cannot be removed by surface scraping (~2-3 inches). This effective diameter usually lies in the range 0.20-0.35 mm. In addition, the coefficient of uniformity, $C_u = d_{60}/d_{10}$, should be less than 3.

The sand in a filter should consist of medium sand with few fines meeting ASTM C 33 size gradation (by weight) or equivalent as given in the table below.

U.S. Sieve Size	Percent Passing
3/8 inch	100
U.S. No. 4	95 to 100
U.S. No. 8	80 to 100
U.S. No. 16	50 to 85
U.S. No. 30	25 to 60
U.S. No. 50	5 to 30
U.S. No. 100	Less than 10

Finally, the silica (SiO_2) content of the sand should be greater than 95% by weight.

Underdrain

- 1) There are several underdrain system options which can be used in the design of a sand filter:
 - a. A central underdrain collection pipe with lateral collection pipes in an 8 inch minimum gravel backfill or drain rock bed.
 - b. Longitudinal pipes in an 8 inch minimum gravel backfill or drain rock bed, with a collection pipe at the outfall.
 - c. Small sand filters may use a single underdrain pipe in an 8 inch minimum gravel backfill or drain rock bed.
- 2) All underdrain pipes and connectors should be 6 inches or greater so they can be cleaned without damage to the pipe. Clean-out risers with diameters equal to the underdrain pipe should be placed at the terminal ends of all pipes and extend to the surface of the filter. A valve box should be provided for access to the cleanouts and the cleanout assembly should be water tight to prevent short circuiting of the sand filter.
- 3) The underdrain pipe should be sized and perforated as to ensure free draining of the sand filter bed. Round perforations should be at least 1/2-inch in diameter and the pipe should be laid with holes downward.
- 4) The maximum perpendicular distance between any two lateral collection pipes or from the edge of the filter and the collection pipes should be 9 feet.
- 5) All pipes should be placed with a minimum slope of 0.5%.
- 6) The invert of the underdrain outlet should be above the seasonal high groundwater level.

- 7) At least 8 inches of gravel backfill should be maintained over all underdrain piping, and at least 6 inches should be maintained on both side and beneath the pipe to prevent damage by heavy equipment during maintenance. Either drain rock or gravel backfill may be used between pipes.
- 8) The bottom gravel layer should have a diameter at least 2X the size of the openings into the drainage system. The grains should be hard, preferably rounded, with a specific gravity of at least 2.5, and free of clay, debris and organic impurities.
- 9) Either a geotextile fabric or a two-inch transition gradation layer (preferred) should be placed between the sand layer and the drain rock or gravel backfill layer. If a geotextile is used, one inch of drain rock or gravel backfill should be placed above the fabric. This allows for a transitional zone between sand and gravel and may reduce pooling of water at the liner interface. The geotextile should meet the following minimum materials requirements.

Geotextile Property	Value	Test Method
Trapezoidal Tear (lbs)	40 (min)	ASTM D4533
Permeability (cm/sec)	0.2 (min)	ASTM D4491
AOS (sieve size)	#60 - #70 (min)	ASTM D4751
Ultraviolet resistance	70% or greater	ASTM D4355

Flow Spreader

- 1) A flow spreader should be installed at the inlet along one side of the filter to evenly distribute incoming runoff across the filter and to prevent erosion of the filter surface.
 - a. If the sand filter is curved or an irregular shape, a flow spreader should be provided for a minimum of 20 percent of the filter perimeter.
 - b. If the length-to-width ratio of the filter is 2:1 or greater, a flow spreader should be located on the longer side and for a minimum length of 20 percent of the facility perimeter.
 - c. In other situations, use good engineering judgment in positioning the spreader.
- 2) Erosion protection should be provided along the first foot of the sand bed adjacent to the flow spreader. Geotextile weighted with sand bags at 15-foot intervals may be used. Quarry spalls may also be used.

Vegetation

- 1) The use of vegetation in sand filters is optional. However, no top soil should be added to the sand filter bed because the fine-grained materials (silt and clay) would reduce the hydraulic capacity of the filter.
- 2) Growing grass or other vegetation requires the selection of species that can tolerate the demanding environment of a sand filter bed. Plants not receiving sufficient dry weather flows should be able to withstand long periods of drought during summer periods, followed by periods of saturation during storm events. A horticultural specialist should be consulted for advice on species selection.
- 3) A sod grown in sand may be used on the sand surface as long as there is no clay in the sand substrate and the particle size gradation of the substrate meets the sand filter specifications. No other sod should be used due to the high clay content in most sod soils.
- 4) To prevent uses that could compact and damage the filter surface, permanent structures are not permitted on sand filters (e.g. playground equipment).

Emergency Overflow Structure

Sand filters may only be placed off-line, but an emergency overflow must still be provided in the event the filter becomes clogged. The overflow structure must be able to safely convey flows from the stormwater quality design storm to the downstream conveyance system or other acceptable discharge point.

Side Slopes

- 1) Interior side slopes above the stormwater quality design depth and up to the emergency overflow water surface steeper than 4:1 (H:V) should be stabilized to prevent erosion with a method approved by the local permitting authority.
- 2) Exterior side slopes steeper than 2:1 (H:V) should be stabilized to prevent erosion with a method approved by the local permitting authority.
- 3) For any slope (interior or exterior) greater than 2:1 (H:V), a geotechnical investigation and report must be submitted and approved by the local permitting authority.
- 4) Pond walls may be vertical retaining walls, provided: (a) they are constructed of reinforced concrete, (b) a fence, which prevents access, is provided along the top of the wall or further back, and (c) the design is stamped by a licensed civil engineer and approved by the County.

Embankments

- 1) Embankments (earthen slopes or berms) may be used for detaining or redirecting the flow of water.
- 2) The minimum top width of all berm embankments should be 20 feet, or as approved by the geotechnical engineer.
- 3) Basin berm embankments should be constructed on native consolidated soil (or adequately compacted and stable fill soils analyzed by a licensed geotechnical engineer) free of loose surface soil materials, roots, and other organic debris.
- 4) Earthworks should be in accordance with Section 300-6 of the Standard Specifications for Public Works Construction, most recent edition.
- 5) Basin berm embankments greater than 4 feet in height should be constructed by excavating a key equal to 50% of the berm embankment cross-sectional height and width. This requirement may be waived if specifically recommended by a licensed geotechnical engineer.
- 6) The berm embankment should be constructed of compacted soil (95% minimum dry density, modified proctor method per ASTM D1557), placed in 6-inch lifts.

Maintenance Access

Maintenance access road(s) shall be provided to the control structure and other drainage structures associated with the basin (e.g., inlet, emergency overflow or bypass structures). Manhole and catch basin lids should be in or at the edge of the access road.

An access ramp is required for removal of sediment with a backhoe or loader and truck. The ramp should extend to the bottom of the sand filter.

Landscaping Outside of the Facility

A sand filter can add aesthetics to a site and should be incorporated into a project's landscape design. Interior side slopes may be stepped with flat areas to provide informal seating with a game or play area below. Perennial beds may be planted above the overflow water surface elevation. Large shrubs and trees are not recommended, however, as shading limits evaporation and falling leaves can clog the filter surface. If a sand filter area is intended for recreational uses, such as a volleyball area, the interior side slopes of the filter embankment should be no steeper than 3:1 and may be stepped.

- 1) No trees or shrubs may be planted within 10 feet of inlet or outlet pipes or manmade drainage structures such as spillways, flow spreaders, or earthen embankments. Species with roots that seek water, such as willow or poplar, should not be used within 50 feet of pipes or manmade structures.
- 2) Prohibited non-native plant species will not be permitted. For more information on invasive weeds, including biology and control of listed weeds, look at the

[encycloweedia](#) located at the California Department of Food and Agriculture website at or the California Invasive Plant Council website at www.cal-ipc.org.

Operations and Maintenance

Sand filters are subject to clogging by fine sediment, oil and grease, and other debris (e.g., trash and organic matter such as leaves). Filters and pretreatment facilities should be inspected every 6 months during the first year of operation. Inspection should also occur immediately following a storm event to assess the filtration capacity of the filter. Once the filter is performing as designed, the frequency of inspection may be reduced to once per year.

Most of the maintenance should be concentrated on the pretreatment practices, such as buffer strips and swales upstream of the trench to ensure that sediment does not reach the infiltration trench. Regular inspection should determine if the sediment removal structures require preventative maintenance.

Inspect basin a minimum of twice a year, before and after the rainy season, after large storm events, or more frequently if needed. Some important items to check for include: differential settlement, cracking; erosion, leakage, or tree growth on the embankment; the condition of the riprap in the inlet, outlet and pilot channels; sediment accumulation in the basin; and the vigor and density of the vegetation on the basin side slopes and floor. Correct observed problems as necessary.

- Remove litter and debris from banks and basin bottom as required.
- Repair erosion to banks and bottom as required.
- Check infiltration rate of sand bed twice annually, once after significant rainfall.
- Scarify top 3 to 5 inches of filters surface by raking once annually or as required to restore infiltration rate of the filter.
- Clean forebay every two years at a minimum, to avoid accumulation in main basin.
- Inspect outlet for clogging a minimum of twice a year, before and after the rainy season, after large storms, and more frequently if needed. Correct observed problems as necessary.

TCM-5: Cartridge Media Filter

Cartridge media filters are manufactured devices that typically consist of a series of cylindrical vertical filters contained in a catch basin, manhole, or vault that provide treatment through filtration and sedimentation. The manhole or vault may be divided into multiple chambers where the first chamber acts as a pre-settling basin for removal of coarse sediment while another chamber acts as the filter bay and houses the filter cartridges.

Cartridge Media Filters

Photo Credits: Contech Stormwater Solutions, Inc.

Application

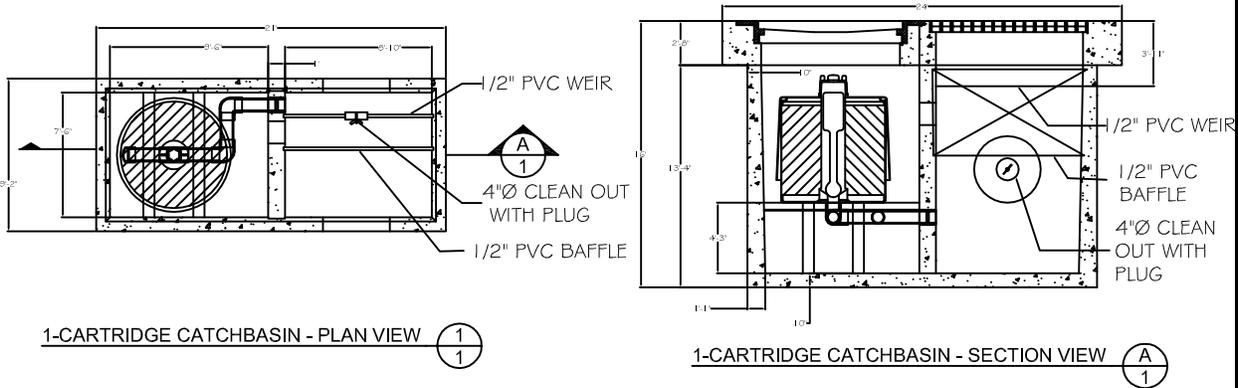

- Parking lots
- Roadways
- Playgrounds
- Outdoor eating areas

Preventative Maintenance

- Filter media replacement
- Solids removal from vault, manhole, or catch basin
- Inspect for inlet and outlet for clogging

Limitations

As with all filtration systems, use in catchments that have significant areas of non-stabilized soils can lead to premature clogging.

Design Criteria

- 1) Cartridge media filter BMP vendors are constantly updating and expanding their product lines, so refer to the latest design guidance from each of the vendors.
- 2) Selected filter media should target pollutants of concern. A combination of media is often recommended to maximize pollutant removal. Perlite is effective for removing TSS and oil and grease. Zeolite removes soluble metals, ammonium, and some organics. Vendors also offer proprietary medias (such as leaf compost or activated carbon) that are designed to remove soluble metals, organics, and other pollutants.
- 3) Manufacturers try to distinguish their products through innovative designs that aim at providing self cleaning and draining, uniformly loaded, and clog resistant cartridges that functional properly over a wide range of hydraulic loadings and pollutant concentrations.
- 4) All stormwater vaults containing cartridge filters that have standing water for longer than 72 hours can become a breeding area for mosquitoes. The selected BMP should have a system to completely drain the vault, such as weep holes in the bottom of the vault.

Sizing

- 1) Cartridge media filters should be sized to capture and treat the stormwater quality design flow rate.
- 2) Proprietary cartridge media filter devices, like most proprietary BMPs, and auxiliary components such as media, screens, baffles, and sumps are selected based onsite-specific conditions such as the loading that is expected and the desired frequency of maintenance. Sizing of proprietary devices is reduced to a simple process whereby a model can simply be selected from a table or a chart based on a few known quantities

(tributary area, location, design flow rate, etc). Most of the manufacturers either size the devices for potential clients or offer calculators on their websites that simplify the design process. For the latest sizing guidelines, refer to the manufacturer's website.

PT-1: Hydrodynamic Separation Device

Hydrodynamic separation devices (alternatively, swirl concentrators) are devices that remove trash, debris, and coarse sediment from incoming flows using screening, gravity settling, and centrifugal forces generated by forcing the influent into a circular motion. By having the water move in a circular fashion, rather than a straight line, it is possible to obtain significant removal of suspended sediments and attached pollutants with less space as compared to wet vaults and other settling devices. Hydrodynamic devices were originally developed for combined sewer overflows (CSOs), where they were used primarily to remove coarse inorganic solids. Hydrodynamic separation has been adapted for stormwater treatment by several manufacturers and is currently used to remove trash, debris, and other coarse solids down to sand-sized particles. Several types of hydrodynamic separation devices are also designed to remove floating oils and grease using sorbent media.

Hydrodynamic Separation

2. Dave Weller, FedCo Construction*

Application

- Parking lots
- Areas adjacent to parking lots
- Areas adjacent to buildings
- Road medians and shoulders

Preventative Maintenance

- Sediment, trash and debris removal
- Vector control

Limitations

Hydrodynamic separation devices are effective for the removal of coarse sediment, trash, and debris, and are useful as pretreatment in combination with other BMP types that target smaller particle sizes.

Hydrodynamic devices represent a wide range of device types that have different unit processes and design elements (e.g., storage versus flow-through designs, inclusion of media filtration, etc.) that vary significantly within the category. These design features likely have significant effects on BMP performance; therefore, generalized performance data for hydrodynamic devices is not practical.

Design Criteria

Proprietary hydrodynamic device BMP vendors are constantly updating and expanding their product lines, so refer to the latest design guidance from each of the vendors. General guidelines on the performance, sizing, operations and maintenance of proprietary devices are provided by the vendors.

Sizing

Hydrodynamic devices shall be sized to capture and treat the stormwater quality design flow rate and to completely drain within 72 hours.

Sizing of proprietary devices is reduced to a simple process whereby a model can simply be selected from a table or a chart based on a few known quantities (tributary area, location, design flow rate, design volume, etc). A few of the manufacturers either size the devices for potential clients or offer calculators on their websites that simplify the design process even further and lessens the possibility of using obsolete design information. For the latest sizing guidelines, refer to the manufacturer's website.

The hydrodynamic separators listed in Table 6-28 are designed to have a permanent pool of water stored within the system. Various methods of vector control are available to prevent mosquito breeding including manhole cover screens and the use of mosquito dunks. In many designs, oil and grease is stored at the water surface and provides a deterrent to mosquito breeding.

Operations and Maintenance

Hydrodynamic devices should be inspected every 6 months during the first year of operation. Inspection should also occur immediately following a storm event to assess the function of the device. Once the device is performing as designed, the frequency of inspection may be reduced to once per year.

PT-2: Catch Basin Insert

Catch basin inserts are manufactured filters or fabric placed in a drop inlet to remove sediment and debris and may include sorbent media (oil absorbent pouches) to remove floating oils and grease. Catch basin inserts are selected specifically based upon the orientation of the inlet.

Application

- Parking lots
- Roads
- Athletic courts
- Outdoor food areas

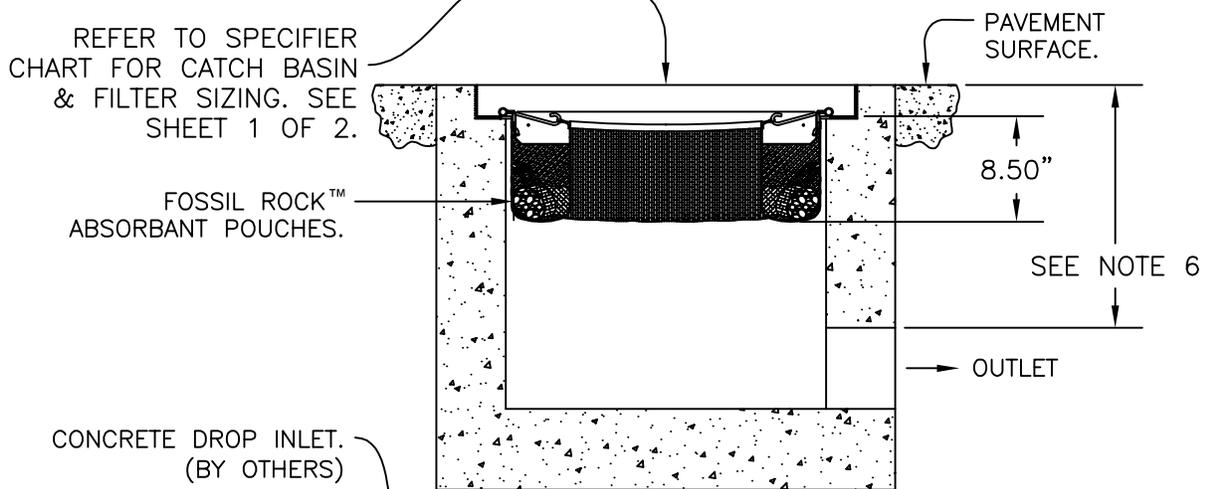

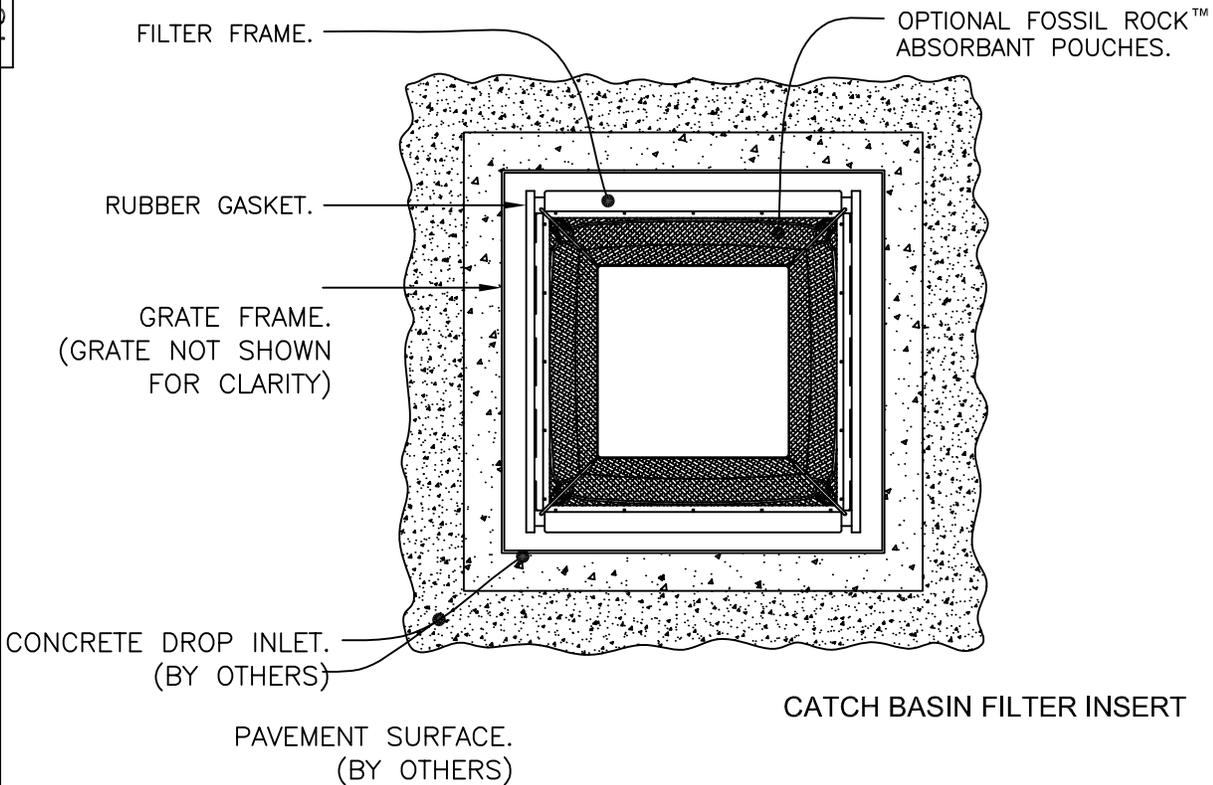

Preventative Maintenance

- After storm inspection
- Sediment removal
- Trash removal
- Filter/sorbent media replacement

Limitations

Catch basin inserts come in such a wide range of configurations that it is practically impossible to generalize the expected performance. Inserts should mainly be used for catching coarse sediments and floatable trash, and are effective as pretreatment in combination with other types of structures that are recognized as water quality treatment BMPs. Trash and large objects can greatly reduce the effectiveness of catch basin inserts with respect to sediment and hydrocarbon capture. Frequent

maintenance and the use of screens and grates to keep trash out may decrease the likelihood of clogging and prevent obstruction and bypass of incoming flows.

Design Criteria

Catch basin inserts shall be sized to capture and treat the stormwater quality design flow rate.

Operations and Maintenance

- 1) Trash, debris, and sediment around insert grate and inside chamber requiring trash to be cleared.
- 2) Repair filter media if damaged or severely clogged.
- 3) Inspection of catch basin insert after each storm greater than 0.2 inches is recommended.

7 MAINTENANCE PLAN

This chapter identifies the basic information that should be included in a maintenance plan. Refer to Fact Sheets for individual control measures in Chapter 6 regarding device-specific maintenance requirements.

7.1 Site Map

- 1) Provide a site map showing boundaries of the site, acreage and drainage patterns/contour lines. Show each discharge location from the site and any drainage flowing onto the site. Distinguish between soft and hard surfaces on the map.
- 2) Identify locations of existing and proposed storm drain facilities, private sanitary sewer systems and grade-breaks for purposes of pollution prevention.
- 3) With legend, show locations of expected sources of pollution generation (outdoor work and storage areas, heavy traffic areas, delivery areas, trash enclosures, fueling areas, industrial clarifiers, wash-racks, etc). Identify any areas having contaminated soil or where toxins are stored or have been stored/disposed of in the past.
- 4) With legend, indicate types and locations of stormwater management control measures which will be built to permanently control stormwater pollution. Distinguish between pollution prevention, treatment, sewer diversion, and containment devices.

7.2 Baseline Descriptions

- 1) List the property owners and persons responsible for operation and maintenance of the stormwater management control measures onsite. Include phone numbers and addresses.
- 2) Identify the intended method of providing financing for operation, inspection, routine maintenance and upkeep of stormwater control measures.
- 3) List all permanent stormwater control measures. Provide a brief description of stormwater management control measures selected and if appropriate, facts sheets or additional information.
- 4) As appropriate for each stormwater control measure provide:
 - a. A written description and check list of all maintenance and waste disposal activities that will be performed. Distinguish between the maintenance appropriate for a 2-year establishment period and expected long-term maintenance. For example, maintenance requirements for vegetation in a constructed wetland may be more intensive during the first few years until the vegetation is established. The post-establishment maintenance

plan should address maintenance needs (e.g., pruning, irrigation, weeding) for a larger, more stable system. Include maintenance performance procedures for facility components that require relatively unique maintenance knowledge, such as specific plant removal / replacement, landscape features, or constructed wetland maintenance. These procedures should provide enough detail for a person unfamiliar with maintenance to perform the activity, or identify the specific skills or knowledge necessary to perform and document the maintenance.

- b. A description of site inspection procedures and documentation system, including record-keeping and retention requirements.
 - c. An inspection and maintenance schedule, preferably in the form of a table or matrix, for each activity for all facility components. The schedule should demonstrate how it will satisfy the specified level of performance, and how the maintenance / inspection activities relate to storm events and seasonal issues.
 - d. Identification of the equipment and materials required to perform the maintenance.
- 5) As appropriate, list all housekeeping procedures for prohibiting illicit discharges or potential illicit discharges to the storm drain. Identify housekeeping BMPs that reduce maintenance of Treatment Control Measures. These procedures are listed based on facility operations and can be found in the Ventura County Industrial/Commercial Clean Business Program document.

7.3 Spill Plan

- 1) Provide emergency notification procedures (phone and agency/persons to contact)
- 2) As appropriate for site, provide emergency containment and cleaning procedures.
- 3) Note downstream receiving water bodies or wetlands which may be affected by spills or chronic untreated discharges.
- 4) As appropriate, create an emergency sampling procedure for spills. (Emergency sampling can protect the property owner from erroneous liability for downstream receiving area clean-ups).

7.4 Facility Changes

Operational or facility changes which significantly affect the character or quantity of pollutants discharging into the stormwater management control measures will require modifications to the Maintenance Plan and/or additional stormwater control measures.

7.5 Training

- 1) Identify appropriate persons to be trained and assure proper training.
- 2) Training to include:
 - a. Good housekeeping procedures defined in the plan.
 - b. Proper maintenance of all pollution mitigation devices.
 - c. Identification and cleanup procedures for spills and overflows.
 - d. Large-scale spill or hazardous material response.
 - e. Safety concerns when maintaining devices and cleaning spills.

7.6 Basic Inspection and Maintenance Activities

- 1) Create and maintain onsite, a log for inspector names, dates and stormwater control measure devices to be inspected and maintained. Provide a checklist for each inspection and maintenance category.
- 2) Once annually, perform testing of any mechanical or electrical devices prior to wet weather.
- 3) Report any significant changes in stormwater management control measures to the site management. As appropriate, assure mechanical devices are working properly and/or landscaped BMP plantings are irrigated and nurtured to promote thick growth.
- 4) Note any significant maintenance requirements due to spills or unexpected discharges.
- 5) As appropriate, perform maintenance and replacement as scheduled and as needed in a timely manner to assure stormwater management control measures are performing as designed and approved.
- 6) Assure unauthorized low-flow discharges from the property do not by-pass stormwater control measures.
- 7) Perform an annual assessment of each pollution generation operation and its associated stormwater management control measures to determine if any part of the pollution reduction train can be improved.

7.7 Revisions of Pollution Mitigation Measures

If future correction or modification of past stormwater management control measures or procedures is required, the owner shall obtain approval from the governing stormwater

agency prior to commencing any work. Corrective measures or modifications shall not cause discharges to bypass or otherwise impede existing stormwater control measures.

7.8 Monitoring & Reporting Program

- 1) The governing stormwater agency may require a Monitoring & Reporting Program to assure the stormwater management control measures approved for the site are performing according to design.
- 2) If required by local permitting agency, the Maintenance Plan shall include performance testing and reporting protocols.

A.2 Glossary

Automotive Repair Shop: A facility that is categorized in any one of the following Standard Industrial Classification (SIC) codes: 5013, 5014, 5541, 7532-7534, or 7536-7539.

Backfill: Earth or engineered material used to refill a trench or an excavation.

Berm: An earthen mound used to direct the flow of runoff around or through a structure.

Best Management Practice (BMP): Any program, technology, process, siting criteria, operational methods or measures, or engineered systems, which when implemented prevent, control, remove, or reduce pollution.

Best Management Practices (BMPs): Includes schedules of activities, prohibitions of practices, maintenance procedures, and other management practices to prevent or reduce the pollution of waters of the United States. BMPs also include treatment requirements, operating procedures, and practices to control plant site runoff, spillage or leaks, sludge or waste disposal, or drainage from raw material storage.

Biofiltration: The simultaneous process of filtration, infiltration, adsorption, and biological uptake of pollutants in stormwater that takes place when runoff flows over and through vegetated areas.

Bioretention Facility: A facility that utilizes soil infiltration and both woody and herbaceous plants to remove pollutants from stormwater runoff. Runoff is typically captured and infiltrated or released over a period of 24 to 48 hours.

Blue Roof: A roof that is designed to store rainwater, typically in a cistern-type device.

Brown Roof: A type of green roof which focuses on biodiversity and locally-sourced material.

Buffer Strip or Zone: Strip of erosion-resistant vegetation over which stormwater runoff is directed.

Capacity: The capacity of a stormwater drainage facility is the flow volume or rate that the facility (e.g., pipe, basin, vault, swale, ditch, drywell, etc.) is designed to safely contain, receive, convey, reduce pollutants from, or infiltrate stormwater to meet a specific performance standard. There are different performance standards for pollution reduction, flow control, conveyance, and destination/ disposal, depending on location.

Catch Basin: Box-like underground concrete structure with openings in curbs and gutters designed to collect runoff from streets and pavements.

Check Dam: Small temporary barrier, grade control structure, or dam constructed across a swale, drainage ditch, or area of concentrated flow with the intent to slow or stop runoff.

Clean Water Act (CWA): (33 U.S.C. 1251 et seq.) requirement of the National Pollutant Discharge Elimination System (NPDES) program are defined under Sections 307, 402, 318 and 405 of the CWA.

Commercial Development: Any development on private land that is not heavy industrial or residential. The category includes, but is not limited to: hospitals, laboratories and other medical facilities, educational institutions, recreational facilities, plant nurseries, multi-apartment buildings, car wash facilities, mini-malls and other business complexes, shopping malls, hotels, office buildings, public warehouses and other light industrial complexes.

Conduit: Any channel or pipe for directing the flow of water.

Construction General Permit: A NPDES permit issued by the State Water Resources Control Board (SWRCB) for the discharge of stormwater associated with construction activity from soil disturbance of five (5) acres or more.

Control Device: A device used to hold back or direct a calculated amount of stormwater to or from a stormwater management facility. Typical control structures include vaults or manholes fitted with baffles, weirs, or orifices.

Conveyance System: Any channel or pipe for collecting and directing the Stormwater.

Culvert: A covered channel or a large diameter pipe that crosses under a road, sidewalk, etc.

Dead-end Sump: A below surface collection chamber for small drainage areas that is not connected to the public storm drainage system. Accumulated water in the chamber must be pumped and disposed in accordance with all applicable laws.

Designated Public Access Points: Any pedestrian, bicycle, equestrian, or vehicular point of access to jurisdictional channels in the area of Ventura County subject to permit requirements.

Detention: The temporary storage of stormwater runoff to allow treatment by sedimentation and metered discharge of runoff at reduced peak flow rates.

Detention Facility: A facility designed to receive and hold stormwater and release it at a slower rate, usually over a number of hours. The full volume of stormwater that enters the facility is eventually released.

Detention Tank, Vault, or Oversized Pipe: A structural subsurface facility used to provide flow control for a particular drainage basin.

Development: any construction, rehabilitation, redevelopment or reconstruction of any public or private residential project (whether single-family, multi-unit or planned unit development); industrial, commercial, retail and any other non-residential projects, including public agency projects; or mass grading for future construction.

Directly Adjacent: Situated within 200 feet of the contiguous zone required for the continued maintenance, function, and structural stability of the environmentally sensitive area.

Directly Connected Impervious Area (DCIA): The area covered by a building, impermeable pavement, and/ or other impervious surfaces, which drains directly into the storm drain without first flowing across permeable land area (e.g. turf buffers).

Directly Discharging: Outflow from a drainage conveyance system that is composed entirely or predominantly of flows from the subject, property, development, subdivision, or industrial facility, and not commingled with the flows from adjacent lands.

Discharge: A release or flow of Stormwater or other substance from a conveyance system or storage container.

Disturbed Area: Any area that is altered as a result of land disturbance, such as: clearing, grading, grubbing, stockpiling and excavation.

Drainage Basin: A specific area that contributes stormwater runoff to a particular point of interest, such as a stormwater management facility, drainageway, wetland, river, or pipe.

Effective Impervious Area (EIA): That portion of the surface area that is hydrologically connected via sheet flow over a hardened conveyance or impervious surface without any intervening medium to mitigate flow volume.

Environmentally Sensitive Area (ESA): An area “in which plant or animal life or their habitats are either rare or especially valuable because of their special nature or role in an ecosystem and which would be easily disturbed or degraded by human activities and developments” (California Public Resources Code § 30107.5). Areas subject to stormwater mitigation requirements are: 303(d) listed water bodies in all reaches that are unimproved, all California Coastal Commission’s *Environmentally Sensitive Habitat Areas* as delineated on maps in Local Coastal Plans, and Regional Water Quality Control Board’s Basin Plan Rare, Threatened or Endangered Species (RARE) and Preservation of Biological Habitats (BIOL) designated waterbodies. The California Department of Fish and Game’s (CDFG) *Significant Natural Areas* map will be considered for inclusion as the department field-verifies the designated locations. Watershed restoration projects will be considered for inclusion as the department field verifies the designated locations.

Erosion: The wearing away of land surface by wind or water. Erosion occurs naturally from weather or runoff, but can be intensified by land-clearing practices relating to farming; residential, commercial, or industrial development; road building; or timber cutting.

Excavation: The process of removing earth, stone, or other materials, usually by digging.

Existing Urban Area: Existing urban areas and corresponding maps in Appendix B are based on the cities' City Urban Restriction Boundaries (CURB) lines and the Existing Community designation in the unincorporated County. These boundaries are a growth management tool intended to channel growth and protect agricultural and open-space land. The 2011 TGM utilizes existing urban areas (as defined in Appendix B) to provide parameters around eligibility for alternative compliance in two areas: 1) Smart Growth and 2) low income housing projects.

Extended Detention Basin: A surface vegetated basin used to provide flow control for a particular drainage basin. Stormwater temporarily fills the extended detention basin during large storm events and is slowly released over a number of hours, reducing peak flow rates.

Facility: Is a collection of industrial process discharging stormwater associated with industrial activity within the property boundary or operational unit.

Filter Fabric: Geotextile of relatively small mesh or pore size that is used to: (a) allow water to pass through while keeping sediment out (permeable); or (b) prevent both runoff and sediment from passing through (impermeable).

Filter Strip: A gently sloping, densely grassed area used to filter, slow, and infiltrate stormwater.

Flow Control Facility: Any structure or drainage device that is designed, constructed, and maintained to collect, retain, infiltrate, or detain surface water runoff during and after a storm event for the purpose of controlling post-development quantity leaving the site.

Flow Control: The practice of limiting the release of peak flow rates, flow durations, and volumes from a site. Flow control is intended to protect downstream properties, infrastructure, and natural resources from the increased stormwater runoff flow rates and volumes resulting from development.

Grading: The cutting and/or filling of the land surface to a desired shape or elevation.

Green Roof: A roofing system that layers a soil/vegetative cover over a waterproofing membrane. Green roofs rely on highly porous media and moisture retention layers to store intercepted precipitation and to support vegetation that can reduce the volume of stormwater runoff via evapotranspiration

Hazardous Substance: (1) Any material that poses a threat to human health and/or the environment. Typical hazardous substances are toxic, corrosive, ignitable, explosive, or chemically reactive; (2) Any substance named by EPA to be reported if a designated quantity of the substance is spilled in the waters of the United States or if otherwise emitted into the environment.

Hazardous Waste: By-products of society that can pose a substantial or potential hazard to human health or the environment when improperly managed. Possesses at least one of four characteristics (flammable, corrosivity, reactivity, or toxicity), or appears on special EPA lists.

Hillside: Property located in an area with known erosive soil conditions, where the development contemplates grading on any natural slope that is 25 percent or greater.

Hydrodynamic Separation: Flow-through structures with a settling or separation unit to remove sediments and other pollutants in which no outside power source is required, because the energy of the flowing water allows the sediments to efficiently separate. Depending on the type of unit, this separation may be by means of swirl action or indirect filtration.

Illegal Discharges: Any discharge to a municipal separate storm sewer that is not composed entirely of stormwater except discharges authorized by an NPDES permit (other than the NPDES permit for discharges from the municipal separate storm sewer) and discharges resulting from fire fighting activities.

Impervious Surface / Area: A hard surface area which either prevents or retards the entry of water into the predevelopment soil mantle. A hard surface area which causes water to run off the surface in greater quantities or at an increased rate of flow from the flow present under predevelopment conditions. Common impervious surfaces include, but are not limited to, roof tops, walkways, patios, driveways, parking lots or storage areas, (impermeable) concrete or asphalt paving, gravel roads, packed earthen materials, and oiled macadam or other surfaces which similarly impede the natural infiltration of storm water.

Industrial General Permit: A NPDES permit issued by the State Water Resources Control Board for the discharge of Stormwater associated with industrial activity.

Infiltration: The downward entry of water into the surface of the soil.

Infiltration Trench: A linear excavation, backfilled with gravel, used to filter pollutants and infiltrate storm water.

Integrated Pest Management Plan (IPMP): A balanced approach to pest management which incorporates the many aspects of plant health care in ways that mitigate harmful environmental impacts and protect human health.

Inlet: An entrance into a ditch, storm sewer, or other waterway.

Legacy Pollutants: Pollutants that are no longer in production but remain in site soils and groundwater and still have the potential to cause ecological and water quality impacts.

Material Storage Areas: On site locations where raw materials, products, final products, by-products, or waste materials are stored.

Maximum Extent Practicable (MEP): The technology-based permit requirement established by Congress in CWA section 402(p)(3)(B)(iii) that municipal dischargers of stormwater must meet. Technology-based requirements, including MEP, establish a level of pollutant control that is derived from available technology or other controls. MEP requires municipal dischargers to perform at maximum level that is practicable. Compliance with MEP may be achieved by emphasizing pollution prevention and source control BMPs in combination with structural and treatment methods where appropriate. The MEP approach is an ever evolving and advancing concept, which considers technical and economic feasibility.

Municipal Separate Storm Sewer System (MS4) Permit : A NPDES permit issued by the Regional Water Quality Control Board for the discharge of Stormwater from Municipal Separate Storm Sewer Systems.

New Development: Land disturbing activities; structural development, including construction or installation of a building or structure, creation and replacement of impervious surfaces; and land subdivision.

Non-Stormwater Discharge: Any discharge to municipal separate storm drain that is not composed entirely of stormwater. Discharges containing process wastewater, non-contact cooling water, or sanitary wastewater are non-stormwater discharges.

Non-Structural Source Control Measure: Low technology, low cost activities, procedures or management practices designed to prevent pollutants associated with site functions and activities from being discharged with Stormwater runoff. Examples include good housekeeping practices, employee training, standard operating practices, inventory control measures, etc.

Notice of Intent (NOI): A formal notice to State Water Resources Control Board submitted by the owner/developer that a construction project is about to begin. The NOI provides information on the owner, location, type of project, and certifies that the permittee will comply with the conditions of the construction general permit.

NPDES Permit: An authorization, license, or equivalent control document issued by EPA or an approved State agency to implement the requirements of the NPDES program.

Operations and Maintenance (O&M): The continuing activities required to keep storm water management facilities and their components functioning in accordance with design objectives.

Outfall: The point where stormwater discharges from a pipe, channel, ditch, or other conveyance to a waterway.

Parking Lot: Land area or facility for the temporary parking or storage of motor vehicles used personally, for business or for commerce with an impervious surface area of 5,000 square feet or more, or with 25 or more parking spaces.

Permeability: A property of soil that enables water or air to move through it. Usually expressed in inches/hour or inches/day.

Pervious Surface/Area: A surface or area with a surface (i.e., soil, loose rock, permeable pavement, etc.) that allows water to infiltrate (soak) into the ground.

Planter Box: A structural facility filled with topsoil and gravel and planted with vegetation. The planter is completely sealed, and a perforated collection pipe is placed under the soil and gravel, along with an overflow provision, and directed to an acceptable destination point. The storm water planter receives runoff from impervious surfaces, which is filtered and retained for a period of time.

Pollutant: An elemental or physical material that can be mobilized or dissolved by water or air and creates a negative impact to human health and/ or the environment. Pollutants include suspended solids (sediment), heavy metals (such as lead, copper, zinc, and cadmium), nutrients (such as nitrogen and phosphorus), bacteria and viruses, organics (such as oil, grease, hydrocarbons, pesticides, and fertilizers), floatable debris, and increased temperature.

Pollutants of Concern: constituents that have exceeded Basin Plan Objectives, and California Toxics Rule chronic or acute objectives during monitoring at mass emission, receiving water, and land use stations.

Pollution Reduction: The practice of filtering, retaining, or detaining surface water runoff during and after a storm event for the purpose of maintaining or improving surface and/or groundwater quality.

Precipitation: Any form of rain or snow.

Predevelopment: The existing land use condition prior to the proposed development activity.

Practicable: Available and capable of being done, after taking into consideration existing technology, legal issues, and logistics in light of overall project purpose.

Pre-developed Condition: the native vegetation and soils that existed at a site prior to first development. The pre-developed condition may be assumed to be the

typical vegetation, soil, and stormwater runoff characteristics of open space areas in coastal Southern California unless reasonable historic information is provided that the area was atypical.

Pre-project Condition: the condition of the site at the time of the proposed project.

Pretreatment: Treatment of wastewater before it is discharged to a wastewater collection system.

Process Wastewater: Wastewater that has been used in one or more industrial processes.

Project: development, redevelopment, and land disturbing activities. The term is not limited to “project” as defined under CEQA (Reference: California Public Resources Code § 21065).

Public Facility: A street, right-of-way, park, sewer, drainage, storm water management, or other facility that is either currently owned by the City/County or will be conveyed to the City/County for maintenance responsibility after construction.

Rainwater Harvesting: Rainwater harvesting is a BMP that stores and uses rainwater or stormwater runoff. This is consistent with the use of the term “reuse” contained in Order R4-2010-0108.

Receiving Stream: (for purposes of this Manual only) any natural or man-made surface water body that receives and conveys stormwater runoff.

Redevelopment: Land-disturbing activity that results in the creation, addition, or replacement of 5,000 square feet or more of impervious surface area on an already developed site. Redevelopment includes, but is not limited to: the expansion of a building footprint; addition or replacement of a structure; replacement of impervious surface area that is not part of a routine maintenance activity; and land disturbing activities related to structural or impervious surfaces. It does not include routine maintenance to maintain original line and grade, hydraulic capacity, or original purpose of facility, nor does it include emergency construction activities required to immediately protect public health and safety. Note: redevelopment as defined here is not the same as a “Redevelopment Project” as defined by California redevelopment law.

Redevelopment Project Area Master Plan (RPAMP): A plan submitted to the Regional Water Board for approval by a Permittee or a coalition of Permittees to establish standards for redevelopment projects within Redevelopment Project Areas, in consideration of exceptional site constraints that inhibit site-by-site or project-by-project implementation of post-construction requirements. See Section 4.E.IV.3 of [Order R4-2010-0108](#).

Restaurant: A stand-alone facility that sells prepared foods and/or drinks for consumption, including stationary lunch counters and refreshment stands selling prepared foods and/or drinks for immediate consumption (SIC code 5812).

Retail Gasoline Outlet: Any facility engaged in selling gasoline and lubricating oils.

Retention Facility: A facility designed to receive and hold stormwater runoff. Rather than storing and releasing the entire runoff volume, retention facilities permanently retain a portion of the water on-site, where it infiltrates, evaporates, or is absorbed by surrounding vegetation. In this way, the full volume of storm water that enters the facility is not released off-site.

Retrofit: Retrofit projects implement structural treatment BMPs as a stand-alone project, without other site improvements. The BMP sizing requirements of this Technical Guidance Manual do not apply to retrofit projects.

Runoff: Water originating from rainfall and other precipitations (e.g., sprinkler irrigation) that is found in drainage facilities, rivers, streams, springs, seeps, ponds, lakes, wetlands, and shallow groundwater.

Runon: Stormwater surface flow or other surface flow which enters property other than that where it originated.

Secondary Containment: Structures, usually dikes or berms, surrounding tanks or other storage containers and designed to catch spilled material from the storage containers.

Sedimentation: The process of depositing soil particles, clays, sands, or other sediments that were picked up by runoff.

Sediments: Soil, sand, and minerals washed from land into water usually after rain, that accumulate in reservoirs, rivers, and harbors, destroying aquatic animal habitat and clouding the water so that adequate sunlight might not reach aquatic plants.

Site: land or water area where any “facility” or “activity” is physically located or conducted including adjacent land used in connection with the facility or activity.

Source Control BMP or Measure: Any schedules of activities, structural devices, prohibitions of practices, maintenance procedures, managerial practices or operational practices that aim to prevent Stormwater pollution by reducing the potential for contamination at the source of pollution.

Source Control BMPs: Operational practices or design features that prevent pollution by reducing potential pollutants at the source.

Spill Guard: A device used to prevent spills of liquid materials from storage containers.

Spill Prevention Control and Countermeasures Plan (SPCC): Plan consisting of structures, such as curbing, and action plans to prevent and respond to spills of hazardous substances as defined in the Clean Water Act.

Storm Drains: Above and below ground structures for transporting stormwater to streams or outfalls for flood control purposes.

Storm Drain System: Network of above and below-ground structures for transporting stormwater to streams or outfalls.

Storm Event: A rainfall event that produces more than 0.1 inch of precipitation and is separated from the previous storm event by at least 72 hours of dry weather.

Stormwater Discharge Associated with Industrial Activity: Discharge from any conveyance which is used for collecting and conveying stormwater which is related to manufacturing processing or raw materials storage areas at an industrial plant [see 40 CFR 122.26(b)(14)].

Stormwater: Stormwater runoff, snow-melt runoff, surface runoff, and drainage, excluding infiltration and irrigation tailwater.

Structural BMP or Control Measure: Any structural facility designed and constructed to mitigate the adverse impacts of stormwater and urban runoff pollution (e.g. canopy, structural enclosure). The category may include both Treatment Control BMPs and Source Control BMPs.

Total Project Area: Total project area (or “gross project area”) for new development and redevelopment projects is the disturbed, developed, and undisturbed portions within the project’s property (or properties) boundary, at the project scale submitted for first approval. Areas proposed to be permanently dedicated for open space purposes as part of the project are explicitly included in the "total project area." Areas of land precluded from development through a restrictive covenant, conservation easement, or other recorded document for the permanent preservation of open space prior to project submittal shall not be included in the "total project area."

Total Suspended Solids (TSS): Matter suspended in stormwater excluding litter, debris, and other gross solids exceeding 1 millimeter in diameter.

Treatment Control BMP or Measure: Any engineered system designed to remove pollutants by simple gravity settling of particulate pollutants, filtration, biological uptake, media adsorption or any other physical, biological, or chemical process.

Treatment: The application of engineered systems that use physical, chemical, or biological processes to remove pollutants. Such processes include, but are not limited to, filtration, gravity settling, media adsorption, biodegradation, biological uptake, chemical oxidation and UV radiation.

Tributary Area: The area from which all runoff produced flows to the same specific discharge point.

Vegetated Facilities: Stormwater management facilities that rely on plantings to enhance their performance. Plantings can provide wildlife habitat and enhance many facility functions, including infiltration, pollutant removal, water cooling, flow calming, and prevention of erosion.

Vegetated Swale: A long and narrow, trapezoidal or semicircular channel, planted with a variety of trees, shrubs, and grasses or with a dense mix of grasses. Stormwater runoff from impervious surfaces is directed through the swale, where it is slowed and in some cases infiltrated, allowing pollutants to settle out. Check dams are often used to create small ponded areas to facilitate infiltration.

APPENDIX C: SITE SOIL TYPE AND INFILTRATION TESTING

C.1 Introduction

The purpose of site soil and infiltration testing is to more accurately determine where LID and structural treatment BMPs should be located and if infiltration is feasible on the site. The preliminary site assessment, discussed in Section 3, will likely reduce the number of test pit investigations needed by identifying candidate test sites that are most amenable to infiltration. This section summarizes the methods for conducting (1) soil test pit investigations and (2) infiltration testing at key locations identified in the preliminary site assessment that require further investigation.

A qualified soil scientist or geotechnical professional should conduct the test pit investigation and infiltration tests. The professional should be experienced with the testing procedures as well as the hydraulic functioning of the potential BMPs to ensure that additional information regarding BMP siting is acquired during the test pit investigation and infiltration tests.

This appendix is not intended to be applied as a protocol for conducting soil and infiltration testing. Instead, this section is provided to assist in specifying and standardizing soil and infiltration testing techniques across sites within Ventura County where development is occurring.

C.2 Test Pit Investigations

A test pit investigation is an integral part of assessing site soil conditions. Soil maps and hydrologic soil groups are based on regional data and provide only a general understanding of what to expect; however, there are undoubtedly unknowns that will be discovered during these initial field observations. A test pit investigation involves digging or excavating a test pit (deep hole). By excavating a test pit, overall soil conditions (both vertically and horizontally) can be observed in addition to the soil horizons. To maximize the knowledge gained during the test pit investigation, many tests and observations should be conducted during this process.

Test pits should be excavated to a depth at least three feet deeper than the proposed bottom of non-infiltration BMPs and at least eleven feet deeper than the proposed bottom of infiltration BMPs. A project that imports fill must characterize the proposed soil profile at the specified depths. For example, if the proposed depth of fill is 5 feet below grade and an infiltration BMP is to be used in the location of the fill, both the fill and the native subsoil require soil characterization. Figure C-1 illustrates the proposed soil profile that would result with 3 feet of fill. Since the test pit must be excavated to a depth that is 11 feet deeper than the bottom of the proposed infiltration BMP, a test pit investigation of the top 8 feet of native subsoil is required, in addition to the laboratory sample of the fill material. Characterization of the fill material should be conducted in a laboratory. It is recommended that soil compaction is limited in the location of a proposed infiltration BMP.

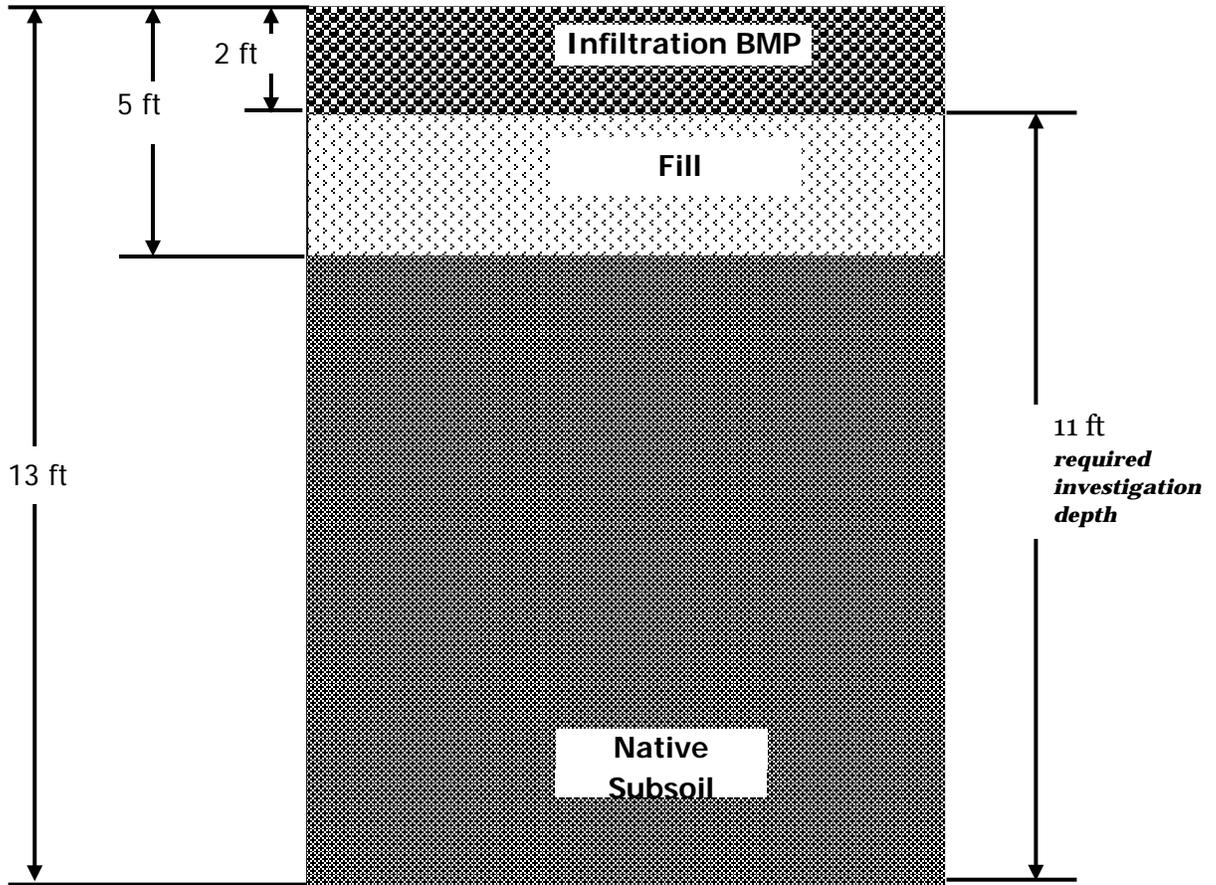

Figure C-1: Post-fill Soil Profile

As the test pit is excavated, the following measurements should be made:

Standard penetration testing to determine the relative density as it changes with depth (minimum intervals of 2 - 3 feet), and

Infiltration testing with at least one test occurring at the proposed bottom of the BMP and one test occurring at the bottom of the test pit (11 feet below the bottom of the infiltration BMP).

In addition, many observations should be made during and after the excavation of the soil pit, including:

- Elevation of groundwater table or indications of seasonally high groundwater table should be noted using the NRCS hydric soil field indicators guide (NRCS, 2003).
- Soil horizon observations, including: depths indicating upper and lower boundaries of the soil horizons, depths to limiting layers (i.e., bedrock and clay), soil textures, colors and their patterns, and estimates of the type and percent of coarse fragments.

- Locations and descriptions of macropores (i.e., pores and roots).
- Other pertinent information/observations.

The number of test pits required depends largely on the specific site and the proposed development plan. Additional tests should be conducted if local conditions indicate significant variability in soil types, geology, water table elevations, bedrock, topography, etc. Similarly, uniform site conditions may indicate that fewer test pits are required. Excessive testing and disturbance of the soil prior to construction is not recommended. When test pit investigations are complete, including infiltration testing, the pits should be refilled with the original soil and the surface replaced with the original topsoil.

C.3 Infiltration Testing

There are a variety of infiltration field test methodologies available to determine the infiltration rate of a soil. Infiltration tests should be conducted in the field in order to ensure that the measurements are representative of actual site conditions (including inherent heterogeneity). As mentioned above, usually infiltration rates should be determined at a minimum of two locations in each test pit and one must be conducted at the proposed bottom depth of the BMP. The actual number of infiltration tests required depends on the soil conditions; if the soils are highly variable, more tests may be required. To ensure groundwater is protected and that the infiltration BMP is not rendered ineffective by overload, it is important to periodically verify infiltration rates of the constructed BMP(s).

For BMPs that infiltrate water through the surface soil layer (e.g., bioretention areas, permeable pavement), choosing a method that measures infiltration in surface soils is important. For infiltration trenches and drywells, infiltration will occur at a greater depth in the soil matrix; therefore, borehole methods may be more appropriate.

Depending on the type of infiltration BMP and depth at which the infiltration test should be conducted, there are several types of infiltration tests that can be used including: disc permeameters, single and double ring infiltrometers, and borehole permeameters. Disc permeameters are typically used to provide estimates of soil near saturation but can prove to be difficult due to measures of three dimensional flow. This device is also commonly used for assessing infiltration rates of already constructed permeable pavements and is generally not used for assessing infiltration rates prior to site disturbance; therefore, the disc permeameter method will not be discussed further in this Appendix. Single and double ring infiltrometers directly measure vertical flow into the surface of the soil. Double ring infiltrometers account for lateral flow boundary affects with the addition of an outer water reservoir and are generally the preferred method for surface infiltration. Borehole permeameters are best suited to collect infiltration measurements below the soil surface. Two subsurface infiltration methods are discussed below including the Guelph and falling-head permeameters.

C.4 Double Ring Infiltrometer

The double ring infiltrometer method consists of driving two cylinders, one inside the other, into the ground and partially filling them with water and maintaining the liquid at a constant level (ASTM D3385-94). The volume of water added to the inner ring from a separate water reservoir, to maintain the constant head level is comparable to the volume of water infiltrating into the soil. The volume of water added to the inner ring divided by the time period for which the water was added is equal to the infiltration rate. A photograph of a common double ring infiltrometer is provided in Figure C-2.

Figure C-2: Double Ring Infiltrometer

Photo Credit: Geosyntec Consultants (Braga and Fitsik, 2008)

C.5 Borehole Guelph Infiltration Test

For shallow boreholes, the Guelph Permeameter has been developed as a field portable kit. This permeameter consists of a tube that is placed in a hand-drilled shallow borehole and water is provided to the tube through a separate reservoir. Water loss in the reservoir is used to estimate the hydraulic conductivity of the soil, which may be used to calculate infiltration based on various standard models (Soil Moisture Equipment, 2005). A photograph of a Guelph Permeameter is provided in Figure C-3. It is important to remember that this method will include vertical and lateral water flow from the borehole.

Figure C-3: Guelph Permeameter for Shallow Borehole Permeability

Photo Credit: USDA, 2005

C.6 Falling-Head Borehole Infiltration Test

The falling-head borehole infiltration test is commonly applied to assess infiltration at greater depths (e.g. 5 - 25 ft). The method is generally performed according to United States Bureau of Reclamation procedure 7300-89 (USBR, 1990). Caltrans has used the method to site stormwater infiltration structures (Caltrans, 2003). Essentially the method consists of boreholes, installing well casing with slots cut to release water at the target depths, backfilling the borehole, adding pre-soak water, and then filling again with water and recording the stage loss. An example diagram is shown in Figure C-4.

The testing procedures are summarized as follows:

- 1) Remove any smeared soil surfaces to provide a natural soil interface for testing the percolation of water. Remove all loose material. The U.S. EPA recommends scratching the sides with a sharp pointed instrument. (Note: upon tester's discretion, a 2-inch layer of coarse sand or fine gravel may be placed to protect the bottom from scouring and sediment.) Fill casing with clean water and allow to pre-soak for 24 hours or until the water has completely infiltrated.
- 2) Refill casing and monitor water level (distance from top of casing to top of water) for 1 hour. Repeat this procedure a total of four times. (Note: upon tester's discretion, the final field rate may either be the average of the four observations

or the value of the last observation. The final rate shall be reported in inches per hour.)

- 3) Testing may be done through a boring or open excavation.
- 4) The location of the test must be near the proposed facility.
- 5) Upon completion of the testing, the casings shall be immediately pulled and the test pit shall be back-filled.

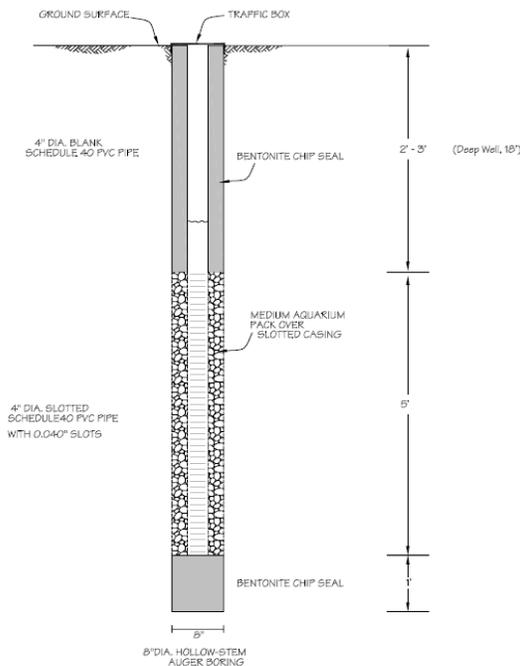

Figure C-4: Falling-Head Permeameter for Deep Borehole Permeability

Diagram Credit: Group Delta Consultants, 2008

C.7 Laboratory Soil Tests

If fill materials imported from off-site are part of an infiltration BMP design, a laboratory test is required to determine the infiltration rate of the fill soil. A sample of the fill soil from each area where a BMP will be located must be tested. The soil sample must be compacted to the same degree that will be present after final grading. Once prepared, the sample should be sent to a specialty laboratory to conduct a test of the infiltration rate. These results may then be used to assess the applicability of a specific BMP.

C.8 Assessment of Test Results

The results from field infiltration methods should be examined to consider data variability and sample distribution to determine if there has been adequate sampling. If the spatial variability (heterogeneity) is large, then additional field measurements may be necessary. The infiltration results should be compared to the information gathered on site soils and geology to see if they are consistent. The results of the site soils and infiltration testing may then be used in the siting, selection, sizing, and design of LID site design techniques and structural treatment BMPs.

APPENDIX D : BMP PERFORMANCE GUIDANCE

D.1 Permit Requirement

Part 3, Section A.3 of [Order R4-2010-0108](#) states the following:

3. *Each Permittee shall require that treatment control BMPs being implemented under the provisions of this Order shall be designed, at a minimum, to achieve the BMP performance criteria for storm water pollutants likely to be discharged as identified in Attachment “C”, for an 85th percentile 24-hour runoff event determined as the maximized capture storm water volume for the area using a 48 to 72-hour draw down time, from the formula recommended in Urban Runoff Quality Management, WEF Manual of Practice No. 23/ASCE Manual of Practice No. 87, (1998). Expected BMP pollutant removal performance for effluent quality was developed from the WERF-ASCE/ U.S. EPA International BMP Database. Permittees shall select Treatment BMPs based on the primary class of pollutants likely to be discharged from the site/facility (e.g. metals from an auto repair shop). Permittees may develop guidance for appropriate Treatment BMPs for project type based on Attachment “C”. For the treatment of pollutants causing impairments within the drainage of the impaired waterbody, permittees shall select BMPs from the top three performing BMP categories or alternative BMPs that are designed to meet or exceed the performance of the highest performing BMP for the pollutant causing impairment.*

Attachment C contains the following table:

Effluent Concentrations as Median Values

BMP Category	Total Suspended Solids (mg/L)	Total Nitrate-Nitrogen (mg/L)	Total Copper (µg/L)	Total Lead (µg/L)	Total Zinc (µg/L)
Detention Pond	27	0.48	15.9	14.6	58.7
Wet Pond	10	0.2	5.8	3.4	21.6
Wetland Basin	13	0.13	3.3	2.5	29.2
Biofilter	18	0.36	9.6	5.4	27.9
Media Filter	11	0.66	7.6	2.6	32.2
Hydrodynamic Device	23	0.29	11.8	5	75.1

Expected BMP pollutant performance for effluent quality was developed from the WERF-ASCE/U.S. EPA International BMP Database, 2007

D.2 Using Performance Statistics for BMP Selection

The observed performance of stormwater BMPs provides valuable quantitative information that can be used to infer the potential water quality benefits of stormwater BMP implementation. However, water quality data sets and the statistical methods used to summarize them inherently contain a high level of uncertainty. Consideration of this uncertainty is fundamental to the proper and responsible use of statistics. Some of the key issues that should be considered when

drawing conclusions from data contained in the [ASCE International BMP Database](#) for the purposes of developing BMP selection guidance are discussed below.

Number of Representative BMPs

Some BMP types are not well represented in the [ASCE International BMP Database](#) due to small data sets. For example, the “Wetland Basin” category only included nine studies nationwide as compared to over 50 for biofilters at the time the data analysis was conducted for the MS4 permit (2007). For some pollutants, such as total copper, data are only available for four Wetland Basin studies. While the BMP Database continues to grow, there are currently less than 300 BMP studies included, with only approximately 50 in California. The size of the data set provides an indicator of the reliability of that data in representing the “typical” effluent concentration for that BMP type.

BMP Categorization

The BMP studies within the BMP database represent a wide spectrum of BMP types with a variety of designs and sizing criteria. While some guidance is provided on how to categorize BMPs, data providers are responsible for categorizing their own BMPs. Some of these BMPs could be poorly categorized due to a variety of reasons, such as differences in terminology, missing or inadequately sized treatment components (e.g., forebays, vegetation, or permanent pools) or variable treatment function (e.g., a seasonal wet pond). Ideally, the BMPs should be grouped according to common design components and/or sizing criteria, but there currently aren’t enough data with design information to support such analyses. However, the BMP Database is currently undergoing a restructuring that is redefining or sub-categorizing the current BMP categories within the database.

Statistical Significant Difference between BMP Influent/Effluent

Some of the median effluent values reported in the BMP Database are not statistically different than the median influent values (i.e., no concentration reductions on average). No significant difference may indicate either low influent concentrations or poor performing BMPs for that pollutant. In either case, the effluent value alone would not be a reliable indicator of BMP performance. For example, as summarized in Geosyntec and Wright Water (2008), the data for Wetland Basins, a “top performing” BMP according to Attachment C of the MS4 permit, did not conclusively show statistically significant removals of TSS, nitrate-nitrogen, or total lead. Data for hydrodynamic separators and media filters indicate they are also ineffective at reducing nitrate-nitrogen concentrations.

Statistical Significant Differences in Effluent between BMP Types

The median effluent concentrations of the various BMP types are not necessarily statistically significantly different from each other. Statistical significance can be determined by analyzing whether the 95th percent confidence intervals overlap. The

number of data points and the variability of those data points determine the confidence interval of each median value. If the effluent medians are not statistically significantly different from each other, it may not be possible to determine the “top three” performing BMPs as specified in the MS4 Permit. Confidence intervals about the median effluent concentrations for each BMP type are provided in Geosyntec and Wright Water (2008) (see attached).

D.3 Comparison of the Performance of Biofiltration BMPs and Retention BMPs

Background

Projects that demonstrate technical infeasibility for reducing EIA to $\leq 5\%$ using Retention BMPs are eligible to use Biofiltration BMPs to achieve the EIA performance standard. Section 4.E.III.1.(b) of [Order R4-2010-0108](#) states:

If on-site retention is determined to be technically infeasible pursuant to 4.E.III.2(b), an on-site biofiltration system that achieves equivalent stormwater volume and pollutant load reduction as would have been achieved by on-site retention shall satisfy the EIA limitation.

Volume-based biofiltration BMPs shall be sized to treat 1.5 times the volume not retained using Retention BMPs. The remaining EIA requirement may also be satisfied with flow-based Biofiltration BMPs. Flow-based Biofiltration BMPs shall be sized for the remaining drainage area from which runoff must be retained (A_{Retain}) with a rainfall intensity that varies with time of concentration for the catchment tributary to the flow-based Biofiltration BMP, according to the following. Using this flow-based sizing method will achieve or exceed capture and treatment of 80% of the average annual runoff volume.

<u>Time of Concentration, minutes</u>	<u>Design Intensity for 150% Sizing, in/hr</u>
30	0.24
20	0.25
15	0.28
10	0.31
5	0.35

Methodology

A planning-level analysis was conducted to assess whether the range of Biofiltration BMPs included in the 2010 TGM, sized per these volume- or flow-based sizing criteria, would achieve equivalent pollutant load reduction to Retention BMPs. The following describes the step-wise method taken for the analysis.

Step 1: Estimate the Catchment Annual Load

Assumptions:

- Average Annual Rainfall- 14.5 inches (Oxnard Gauge) (precipitation, P)
- One acre Catchment (area, A)

Calculations:

1) Determine developed runoff coefficients for single-family, multi-family, commercial, and industrial land use types

- Use average imperviousness values from Ventura Hydrology Manual (Exhibit 14B)
- Assume soil group 2/3 (Group C soils) for pervious runoff coefficient (C_p, conservative value = 0.1)
- Use developed runoff coefficient (C_d) equation from hydrology manual:

$$C_d = 0.95 * (\text{imperviousness}) + (C_p) * (1 - \text{imperviousness})$$

2) Calculate Average Annual Runoff Volume (cu-ft) using:

$$V_{\text{avg annual}} = C_d * (P/12) * A * 43560$$

3) Multiply average annual runoff volume by respective event mean concentrations (EMCs) for pollutants of concern to get average annual loads.

- Look at “EMC Arithmetic Means” to see EMCs by land use type.
- EMCs calculated based on LA County Land Use specific data (LACDPW, 2000). Descriptive statistics estimated using the parametric bootstrap method suggested by Singh, Singh, and Engelhardt (1997).
- Pollutants of concern: Total Suspended Solids (TSS), Total Copper, Total Zinc, and Total Nitrogen. TSS is representative of the sediment pollutant class as well as pollutants that are associated with particulates (e.g., total phosphorous, some metals, pesticides, some organics). Copper and zinc represent metals – lead has been removed from the environment using True Source Control (removal of lead from gasoline) and thus is not an important POC for Biofiltration BMP selection and design. Total nitrogen is representative in that it includes all of the species of nitrogen (organic nitrogen, ammonia, nitrate, and nitrite) and instead of focusing on one species (nitrate).

Step 2: Estimate Retention BMP Load Reduction

1) Determine Retention BMP Design volume:

- Design storm = 0.75”
 - Use land use-based coefficients
 - $V_{\text{design}} = C_d \cdot (0.75/12) \cdot A \cdot 43560$
- 2) Determine Retention BMP capture volume using CASQA 48-hour Drawdown Figure for Oxnard Gauge (CASQA, 2003)
- Calculate Unit Basin Storage Volume using:
 - Unit Basin Storage Vol = V_{design} / A
 - Using developed runoff coefficients, interpolate between runoff coefficient lines to determine the percentage of total runoff captured by Retention BMP.
- 3) Determine Annual Load Reduction
- The percentage of the annual load that is reduced is the same as the percentage of runoff captured by the Retention BMP, assuming that all captured runoff is retained. The percent capture calculated in (2) can be multiplied by the catchment annual pollutant load to obtain the load reduction.

Step 3: Estimate Biofiltration BMP Load Reduction

- 1) Determine BMP Design volume as described in 2.a above, except:
- Design storm = $1.5 \cdot 0.75 = 1.125$ inches
- 2) Determine BMP capture volume using CASQA 24-hour Drawdown Figure for Oxnard Gauge (CASQA, 2003) as described in 2.b. above
- 3) Determine annual load reduction. Load reduction in Biofiltration BMPs can occur via two pathways: incidental infiltration and treatment.
- Incidental infiltration in Biofiltration BMPs was discussed in a publication by Strecker, Quigley, Urbonas, and Jones (Strecker et al, 2004). That study observed as much as 40% volume reduction through incidental infiltration. A recent summary of the studies in the ASCE BMP Database found the following average volume reductions: filter strips, 38%; vegetated swales, 48%; and bioretention with underdrain, 61% (Geosyntec, 2011; attached to this appendix).
 - Pollutant Load reduction via incidental infiltration can be calculated as follows (20% is the percent of the captured volume assumed to be reduced via incidental infiltration for this discussion):

$$\text{Load reduced} = \text{Average annual Load} * \text{Percent Runoff Captured by BMP} * 20\%$$

- Load reduction through treatment calculated based on published literature on pollutant removals from biofiltration facilities.
- Load reduction through treatment is calculated as follows:

$$\text{Load reduced} = \text{Average annual Load} * \text{Percent Runoff Captured by BMP} * 80\% * \text{Assumed Average Percent Removal}$$

Note: 80% = 100%-20%, i.e. the captured runoff that was not infiltrated via incidental infiltration

Constituent	Range of Reported Removal Efficiencies from Literature ¹	Selected Removal Efficiency for Effectiveness Evaluation ²	Selected Removal Efficiency for Enhanced Nitrogen Removal ³
TSS	54-89	79	79
Total Zinc	48-96	77	77
Total Copper	33-92	72	72
Total Nitrogen	21-54	25	50

² Removal efficiency for TSS, Total Zinc, and Total Copper represent average of values from literature. Removal efficiency for TN is that expected from a 'standard biofilter', that is, one not designed for enhanced nitrogen removal

³ Removal efficiency for TN represented as average value of removals from bioretention systems with an anaerobic zone for enhanced removal of nitrogen

- The total load reduction is calculated as the sum of the reductions from these two pathways. The percent load reduction is calculated by dividing the total load reduction by the annual pollutant load from the catchment

Step 4: Comparison of Annual Load Reductions

- 1) Load reductions are compared by subtracting the load reduction calculated for Biofiltration BMPs from the load reduction calculated for Retention BMPs to determine the ‘deficit’ load reduction.

Results

Step 1: Estimate the Catchment Annual Load

- 1) Determine developed runoff coefficients for single-family, multi-family, commercial, and industrial land use types

Land Use	Imperviousness	Runoff Coefficient (C)
Single Family Residential	0.3	0.36
Multi Family Residential	0.69	0.69
Commercial	0.85	0.82
Industrial	0.93	0.89

- 2) Calculate Average Annual Runoff Volume (cu-ft), and
- 3) Multiply average annual runoff volume by respective event mean concentrations (EMCs) for pollutants of concern to get average annual loads.

Land Use	Arithmetic Means from Lognormal EMC Statistics			
	TSS (mg/L)	Total Zinc (mg/L)	Total Copper (mg/L)	Total Nitrogen (mg/L as N)
Single Family Residential	124.2	71.9	18.7	3.74
Multi Family Residential	39.9	125.1	12.1	3.31
Commercial	67	237.1	31.4	3.99
Industrial	219.2	537.4	34.5	3.74

Land Use	Average Annual Runoff Volume (cu-ft)	Catchment Pollutant Loads (kg/yr)			
		TSS	Total Zinc	Total Copper	Total Nitrogen
Single Family Residential	18,685	65,716	38	10	1,979
Multi Family Residential	36,134	40,826	128	12	3,387
Commercial	43,292	82,135	291	38	4,891
Industrial	46,871	290,933	713	46	4,964

Step 2: Estimate Retention BMP Load Reduction

- 1) Determine Retention BMP Design volume

Land Use	Design Volume (cu-ft)
Single Family Residential	967
Multi Family Residential	1869
Commercial	2239
Industrial	2424

- 2) Determine Retention BMP capture volume using CASQA 48-hour Drawdown Figure for Oxnard Gauge (CASQA, 2003)

Land Use	Design Volume (cu-ft)	Unit Basin Storage Volume (inches)	Approx % Capture
Single Family Residential	966	0.27	60.0%
Multi Family Residential	1,869	0.51	62.5%
Commercial	2,239	0.62	62.5%
Industrial	2,424	0.67	60.0%

- 3) Determine Annual Load Reduction

Land Use	Average Annual Pollutant Load Reduction (kg/yr) = Influent * Approx % Cap			
	TSS	Total Zinc	Total Copper	Total Nitrogen
Single Family Residential	39,429	23	5.9	1,187
Multi Family Residential	25,516	80	7.7	2,117
Commercial	51,335	182	24.1	3,057
Industrial	174,560	428	27.5	2,978

Land Use	Percent of Total Annual Loads			
	TSS	Total Zinc	Total Copper	Total Nitrogen
Single Family Residential	60.0%	60.0%	60.0%	60.0%
Multi Family Residential	62.5%	62.5%	62.5%	62.5%
Commercial	62.5%	62.5%	62.5%	62.5%
Industrial	60.0%	60.0%	60.0%	60.0%

Step 3: Estimate Biofiltration BMP Load Reduction

- 1) Determine Biofiltration BMP Design volume

Land Use	Design Volume (cu-ft)
Single Family Residential	1,450
Multi Family Residential	2,803
Commercial	3,359
Industrial	3,637

- 2) Determine BMP capture volume using CASQA 24-hour Drawdown Figure for Oxnard Gauge (CASQA, 2003)

Land Use	Design Volume (cu-ft)	Unit Basin Storage Volume (inches)	Approx % Capture
Single Family Residential	1,450	0.40	87.50%
Multi Family Residential	2,803	0.77	87.50%
Commercial	3,359	0.93	90.00%
Industrial	3,637	1.00	87.50%

- 3) Determine annual load reduction. Load reduction in Biofiltration BMPs can occur via two pathways: incidental infiltration and treatment.

Incidental Infiltration Scenario #1: 20% Volume Reduction

Land Use	Pollutant Load Reduction from 20% Incidental Infiltration (kg/yr)			
	TSS	Total Zinc	Total Copper	Total Nitrogen
Single Family Residential	11,500	7	2	346
Multi Family Residential	7,144	22	2	593
Commercial	14,784	52	7	880
Industrial	50,913	125	8	869

Land Use	Pollutant Load Reduction from Standard Treatment (kg/yr)				Enhanced Nitrogen Load Reduction (kg/yr) ¹
	TSS	Total Zinc	Total Copper	Total Nitrogen	Total Nitrogen
Single Family Residential	36,341	21	5	346	693
Multi Family Residential	22,577	69	6	593	1,185
Commercial	46,719	161	20	880	1,761
Industrial	160,886	384	23	869	1,737

¹ Anticipated removal if an anaerobic zone is provided for Enhanced Nitrogen removal.

Land Use	Total Pollutant Load Reduction from Standard Treatment + Incidental Infiltration (20%) (kg/yr)				Enhanced Nitrogen Load Reduction + Incidental Infiltration (20%) (kg/yr)
	TSS	Total Zinc	Total Copper	Total Nitrogen	Total Nitrogen
Single Family Residential	47,841	27	6.7	693	1,039
Multi Family Residential	29,721	91	8.4	1,185	1,778
Commercial	61,503	213	26.8	1,761	2,641
Industrial	211,799	509	31.0	1,737	2,606

Land Use	Percent of Total Annual Loads from Standard Treatment + Incidental Infiltration (20%)				Enhanced Nitrogen % Load Reduction + Incidental Infiltration (20%)
	TSS	Total Zinc	Total Copper	Total Nitrogen	Total Nitrogen
Single Family Residential	72.8%	71.4%	67.7%	35.0%	52.5%
Multi Family Residential	72.8%	71.4%	67.7%	35.0%	52.5%
Commercial	74.9%	73.4%	69.6%	36.0%	54.0%
Industrial	72.8%	71.4%	67.7%	35.0%	52.5%

Step 4: Comparison of Annual Load Reductions

Load reductions are compared by subtracting the load reduction calculated for Biofiltration BMPs from the load reduction calculated for Retention BMPs to determine the ‘deficit’ load reduction.

Land Use	Biofiltration Pollutant Load Reduction Deficit - Standard Treatment + Incidental Infiltration (20%) (kg/yr)				Enhanced Nitrogen + Incidental Infiltration (20%) Pollutant Load Reduction Deficit (kg/yr)
	TSS	Total Zinc	Total Copper	Total Nitrogen	Total Nitrogen
Single Family Residential	-8,412	-4	-0.8	495	148
Multi Family Residential	-4,205	-11	-0.6	931	339
Commercial	-10,168	-32	-2.7	1,296	416
Industrial	-37,239	-81	-3.5	1,241	372

Note: a negative deficit means Biofiltration has a higher pollutant load reduction than Retention.

Land Use	Biofiltration Pollutant Load Reduction Deficit - Standard Treatment + Incidental Infiltration (20%) (%)				Enhanced Nitrogen + Incidental Infiltration (20%) Pollutant Load Reduction Deficit (%)
	TSS	Total Zinc	Total Copper	Total Nitrogen	Total Nitrogen
Single Family Residential	-12.8%	-11.4%	-7.7%	25.0%	7.5%
Multi Family Residential	-10.3%	-8.9%	-5.2%	27.5%	10.0%
Commercial	-12.4%	-10.9%	-7.1%	26.5%	8.5%
Industrial	-12.8%	-11.4%	-7.7%	25.0%	7.5%

Conclusion: Biofiltration BMPs sized for 1.5 times the SQDV, with an average incidental infiltration of 20% of the average annual runoff volume, which is a conservative estimate of incidental infiltration for all types of Biofiltration Treatment Measures, provide equivalent pollutant load reduction to Retention BMPs for TSS and metals.

Incidental Infiltration Scenario #2: 40% Volume Reduction

Land Use	Pollutant Load Reduction from 40% Incidental Infiltration (kg/yr)			
	TSS	Total Zinc	Total Copper	Total Nitrogen
Single Family Residential	23,000	13	3	693
Multi Family Residential	14,289	45	4	1,185
Commercial	29,569	105	14	1,761
Industrial	101,827	250	16	1,737

Land Use	Pollutant Load Reduction from Standard Treatment (kg/yr)				Enhanced Nitrogen Load Reduction (kg/yr) ¹
	TSS	Total Zinc	Total Copper	Total Nitrogen	Total Nitrogen
Single Family Residential	27,256	15	3.7	260	519
Multi Family Residential	16,932	52	4.7	445	889
Commercial	35,039	121	14.9	660	1,321
Industrial	120,665	288	17.2	652	1,303

¹ Anticipated removal if an anaerobic zone is provided for Enhanced Nitrogen removal.

Land Use	Total Pollutant Load Reduction from Standard Treatment + Incidental Infiltration (40%) (kg/yr)				Enhanced Nitrogen Load Reduction + Incidental Infiltration (40%) (kg/yr)
	TSS	Total Zinc	Total Copper	Total Nitrogen	Total Nitrogen
Single Family Residential	50,256	29	7.2	952	1,212
Multi Family Residential	31,221	97	9.0	1,630	2,074
Commercial	64,608	225	28.8	2,421	3,082
Industrial	222,491	538	33.3	2,389	3,040

Land Use	Percent of Total Annual Loads from Standard Treatment + Incidental Infiltration (40%)				Enhanced Nitrogen % Load Reduction + Incidental Infiltration (40%)
	TSS	Total Zinc	Total Copper	Total Nitrogen	Total Nitrogen
Single Family Residential	76.5%	75.4%	72.6%	48.1%	61.3%
Multi Family Residential	76.5%	75.4%	72.6%	48.1%	61.3%
Commercial	78.7%	77.6%	74.7%	49.5%	63.0%
Industrial	76.5%	75.4%	72.6%	48.1%	61.3%

Step 4: Comparison of Annual Load Reductions

Load reductions are compared by subtracting the load reduction calculated for Biofiltration BMPs from the load reduction calculated for Retention BMPs to determine the ‘deficit’ load reduction.

Land Use	Biofiltration Pollutant Load Reduction Deficit - Standard Treatment + Incidental Infiltration (40%) (kg/yr)				Enhanced Nitrogen + Incidental Infiltration (40%) Pollutant Load Reduction Deficit (kg/yr)
	TSS	Total Zinc	Total Copper	Total Nitrogen	Total Nitrogen
Single Family Residential	-10,827	-6	-1.2	235	-25
Multi Family Residential	-5,705	-17	-1.3	487	42
Commercial	-13,273	-44	-4.7	636	-24
Industrial	-47,931	-110	-5.8	589	-62

Note: a negative deficit means Biofiltration has a higher pollutant load reduction than Retention.

Land Use	Biofiltration Pollutant Load Reduction Deficit - Standard Treatment + Incidental Infiltration (40%) (%)				Enhanced Nitrogen + Incidental Infiltration (40%) Pollutant Load Reduction Deficit (%)
	TSS	Total Zinc	Total Copper	Total Nitrogen	Total Nitrogen
Single Family Residential	-16.5%	-15.4%	-12.6%	11.9%	-1.3%
Multi Family Residential	-14.0%	-12.9%	-10.1%	14.4%	1.2%
Commercial	-16.2%	-15.1%	-12.2%	13.0%	-0.5%
Industrial	-16.5%	-15.4%	-12.6%	11.9%	-1.3%

Conclusion: Biofiltration BMPs sized for 1.5 times the SQDV, with an average incidental infiltration of 40% of the average annual runoff volume, which is representative of vegetated swales and filter strips, provide equivalent pollutant load reduction to Retention BMPs for all of the pollutants of concern.

Incidental Infiltration Scenario #3: 60% Volume Reduction

Land Use	Pollutant Load Reduction from 60% Incidental Infiltration (kg/yr)			
	TSS	Total Zinc	Total Copper	Total Nitrogen
Single Family Residential	34,501	20	5	1,039
Multi Family Residential	21,433	67	6	1,778
Commercial	44,353	157	21	2,641
Industrial	152,740	374	24	2,606

Land Use	Pollutant Load Reduction from Standard Treatment (kg/yr)				Enhanced Nitrogen Load Reduction (kg/yr) ¹
	TSS	Total Zinc	Total Copper	Total Nitrogen	Total Nitrogen
Single Family Residential	18,170	10	2	173	346
Multi Family Residential	11,288	34	3	296	593
Commercial	23,359	81	10	440	880
Industrial	80,443	192	11	434	869

¹ Anticipated removal if an anaerobic zone is provided for Enhanced Nitrogen removal.

Land Use	Total Pollutant Load Reduction from Standard Treatment + Incidental Infiltration (60%) (kg/yr)				Enhanced Nitrogen Load Reduction + Incidental Infiltration (60%) (kg/yr)
	TSS	Total Zinc	Total Copper	Total Nitrogen	Total Nitrogen
Single Family Residential	52,671	30	7.7	1,212	1,385
Multi Family Residential	32,722	102	9.6	2,074	2,371
Commercial	67,712	238	30.7	3,082	3,522
Industrial	233,183	567	35.5	3,040	3,475

Land Use	Percent of Total Annual Loads from Standard Treatment + Incidental Infiltration (60%)				Enhanced Nitrogen % Load Reduction + Incidental Infiltration (60%)
	TSS	Total Zinc	Total Copper	Total Nitrogen	Total Nitrogen
Single Family Residential	80.2%	79.5%	77.6%	61.3%	70.0%
Multi Family Residential	80.2%	79.5%	77.6%	61.3%	70.0%
Commercial	82.4%	81.7%	79.8%	63.0%	72.0%
Industrial	80.2%	79.5%	77.6%	61.3%	70.0%

Step 4: Comparison of Annual Load Reductions

Load reductions are compared by subtracting the load reduction calculated for Biofiltration BMPs from the load reduction calculated for Retention BMPs to determine the ‘deficit’ load reduction.

Land Use	Biofiltration Pollutant Load Reduction Deficit - Standard Treatment + Incidental Infiltration (60%) (kg/yr)				Enhanced Nitrogen + Incidental Infiltration (60%) Pollutant Load Reduction Deficit (kg/yr)
	TSS	Total Zinc	Total Copper	Total Nitrogen	Total Nitrogen
Single Family Residential	-13,242	-7	-1.7	-25	-198
Multi Family Residential	-7,206	-22	-1.9	42	-254
Commercial	-16,378	-56	-6.7	-24	-465
Industrial	-58,623	-139	-8.1	-62	-496

Note: a negative deficit means Biofiltration has a higher pollutant load reduction than Retention.

Land Use	Biofiltration Pollutant Load Reduction Deficit - Standard Treatment + Incidental Infiltration (60%) (%)				Enhanced Nitrogen + Incidental Infiltration (60%) Pollutant Load Reduction Deficit (%)
	TSS	Total Zinc	Total Copper	Total Nitrogen	Total Nitrogen
Single Family Residential	-20.2%	-19.5%	-17.6%	-1.3%	-10.0%
Multi Family Residential	-17.7%	-17.0%	-15.1%	1.2%	-7.5%
Commercial	-19.9%	-19.2%	-17.3%	-0.5%	-9.5%
Industrial	-20.2%	-19.5%	-17.6%	-1.3%	-10.0%

Conclusion: Biofiltration BMPs sized for 1.5 times the SQDV, with an average incidental infiltration of 60% of the average annual runoff volume, which is representative of bioretention with an underdrain, is equivalent to or exceeds the pollutant load reduction of Retention BMPs for all of the pollutants of concern.

APPENDIX E : BMP SIZING WORKSHEETS

E.1 Structural Treatment BMP Sizing Criteria

The BMP sizing criteria for determining the design volume or design flow for a proposed BMP are discussed in this appendix. These criteria must be used for all stormwater BMPs installed in new and re-development projects in Ventura County. This section outlines the rainfall analyses, Ventura County MS4 Permit sizing criteria, and recommended sizing methods for both volumetric and flow-based analysis.

Sizing Criteria

The type of rainfall analysis required depends on whether the BMP is a volume-based or flow-based BMP. This distinction between volume-based and flow-based controls is not always clear, especially in a sequence of BMPs or a treatment train. The following are general guidelines for each type of control.

- Volume-based BMPs are designed to treat a volume of runoff, which is detained for a certain period of time to allow for the settling of solids and associated pollutants. Volume-based BMPs included in this manual are bioretention, planter boxes, infiltration systems, and retention/detention BMPs.
- Flow-based BMPs treat water on a continuous flow basis. Flow-based BMPs included in this manual are vegetated swales, filter strips, filtration systems, and hydrodynamic devices.

The four volume-based and three flow-based BMP sizing criteria included in the Ventura County MS4 Permit (Order No. 09-0057) are included below.

The water quality design volume for volume-based BMPs must be determined using one of the following options:

- 1) The 85th percentile 24-hour runoff event determined as the maximized capture stormwater volume for the area using a 48 to 72-hour draw down time, from the formula recommended in Urban Runoff Quality Management, WEF Manual of Practice No. 23/ASCE Manual of Practice No. 87, (1998); or
- 2) The volume of annual runoff based on unit basin storage water quality volume to achieve 80 percent or more volume treatment; or
- 3) The volume of runoff produced from a 0.75 inch storm event; or
- 4) 80 percent of the average runoff volume using an appropriate public domain continuous flow model [such as Storm Water Management Model (SWMM) or Hydrologic Engineering Center – Hydrologic Simulation Program – Fortran (HEC-HSPF)], using the local rainfall record and relevant BMP sizing and design data.

Flow-based BMPs must be designed to capture and treat the water quality design flow rate generated from one of the following criterion:

- 1) The flow of runoff produced from a rain event equal to at least 0.2 inches per hour intensity; or
- 2) The flow of runoff produced from a rain event equal to at least 2 times the 85th percentile hourly rainfall intensity as determined from local rainfall records; or
- 3) Eight percent of the 50-year storm design flow rate as determined from the method provided below.

These sizing methods are explained below.

Methods for Determining the Water Quality Design Volume

Method 1: Urban Runoff Quality Management (URQM) Approach

The volume-based BMP sizing methodology described in Urban Runoff Quality Management (WEF Manual of Practice No. 23/ASCE Manual of Practice No. 87, (1998), pages 175-178) estimates the “maximized stormwater quality capture volume.” The URQM approach is based on the translation of rainfall to runoff using two regression equations. The first regression equation, which relates rainfall to runoff, was developed using two years of data from more than 60 urban watersheds nationwide. The second regression equation relates mean annual runoff-producing rainfall depths to the “Maximized Water Quality Capture Volume” which corresponds to the “knee of the cumulative probability curve”. This second regression was based on analysis of long-term rainfall data from seven rain gages representing climatic zones across the country. The Maximized Water Quality Capture Volume corresponds to approximately the 85th percentile runoff event, and ranges from 82 to 88%.

The two regression equations that form the URQM approach are as follows:

$$C = 0.858imp^3 - 0.78imp^2 + 0.774imp + 0.04 \tag{Equation E-1}$$

$$P_o = (a \cdot C) \cdot P_6 \tag{Equation E-2}$$

Where:

- C = watershed runoff coefficient (unitless)
- imp = watershed impervious ratio which is equal to the percent total imperviousness divided by 100 (ranges from 0 to 1)
- P_o = maximized detention storage volume based on the volume capture ratio as its basis (watershed inches)

- a = regression constant from least-squares analysis (unit less),
a=1.582 and a=1.963 for 24 and 48 hour draw down,
respectively
- P_6 = mean storm precipitation volume (watershed inches)

P_6 can be determined by two ways: Figure 5.3 in Urban Runoff Quality Management, or by performing analysis on local historical rainfall data. To determine the mean precipitation, EPA's Synoptic Rainfall Analysis Program – SYNOP – can be applied (see *Other Rainfall Analysis Methods* below).

The runoff coefficient equation in the URQM approach (Method 1) is not appropriate for the California BMP Handbook approach (Method 2), as Equation E-4 was developed in conjunction with the regression constants used in Method 1.

Method 2: Treatment of 80% or more of the Total Volume

Most water quality facilities are designed to treat only a portion of the runoff from a given site, as it is not economically feasible to capture 100% of the runoff. The percent of runoff treated by a basin is referred to as the “percent capture”. There are a number of methods which allow calculation of the percent capture, including the California Stormwater Quality Association (CASQA) method (recommended by the 2002 Ventura County Manual), and using the EPA Stormwater Management Model (SWMM).

CASQA Method

The California Stormwater Quality Association (CASQA) BMP Handbook method estimates the basin volume to achieve various levels of volume capture (e.g., 80% for this sizing criterion). In the CASQA BMP Handbook New Development and Redevelopment (2003), a proprietary version of the Storage, Treatment, Overflow, Runoff Model (STORM) is used as the basis for the volume-based BMP sizing criteria. The model results are presented as the relationship between “unit basin storage volume” and “% volume capture” of the BMP”, varying with drawdown time and runoff coefficient. Knowing the drawdown time, the runoff coefficient, and the desired percent capture will yield the “unit basin storage volume”. The “unit basin storage volume” can then be used to size the BMP using the following equation (note that “unit basin storage volume” is given in inches, so units will have to be adjusted accordingly):

$$\text{BMP Volume} = \text{Unit Basin Storage Volume} \times \text{Tributary Area} \quad (\text{Equation E-3})$$

Results for several rain gauges are presented in Appendix D of the CASQA BMP Handbook New Development and Redevelopment (CASQA, 2003). Results are provided for a range of runoff coefficients and for 24 hour and 48 hour drawn down times. In order to use the curves provided in Appendix D, it is necessary to know the

runoff coefficient for the area tributary to the BMP, the drawn down time (a.k.a. drain time) of the facility, and the percent capture goal (e.g., 80%).

Drawdown time is the time required to drain a facility that has reached its design capacity; usually expressed in hours. Drain time is important as it is a surrogate for residence time, which affects the particle settling in the basin. Estimates for design drain time vary, and ideally would be determined based on site-specific information on the size, shape, and density or settling velocity of suspended particulates in the runoff. Because this information is generally not available for a specific site, estimates of appropriate ranges for settling time have generally relied on settling column test information reported in the literature.

An important source of drain time information is settling column tests conducted by Grizzard et. al. (1986) as part of the Nationwide Urban Runoff Program (NURP). Grizzard found that settling times of 48 hours resulted in removals of 80% to 90% of total suspended solids (TSS). Rapid initial removal was also observed in stormwater samples with medium (100 to 215 mg/L) and high (721 mg/L) initial TSS concentrations. For example, at settling times of 24 hours, the 80% to 90% removals were already achieved in samples with medium and high initial TSS, whereas only 50% to 60% removal was achieved in those with low initial TSS.

Given the data provided above, a drain time of 36 to 48 hours is recommended for sizing volume-based BMPs. This is also consistent with the recommendation of vector control agencies that structures be designed to drain in less than 72 hours to minimize mosquito breeding.

The rain gauge that is recommended for use for the area permitted by the Ventura county MS4 Permit (Order No. 09-0057) is the Oxnard Equipment Yard Gauge (168), which has a 40 year rainfall record. The graph included in the CASQA handbook can be seen in Figure E-1 below.

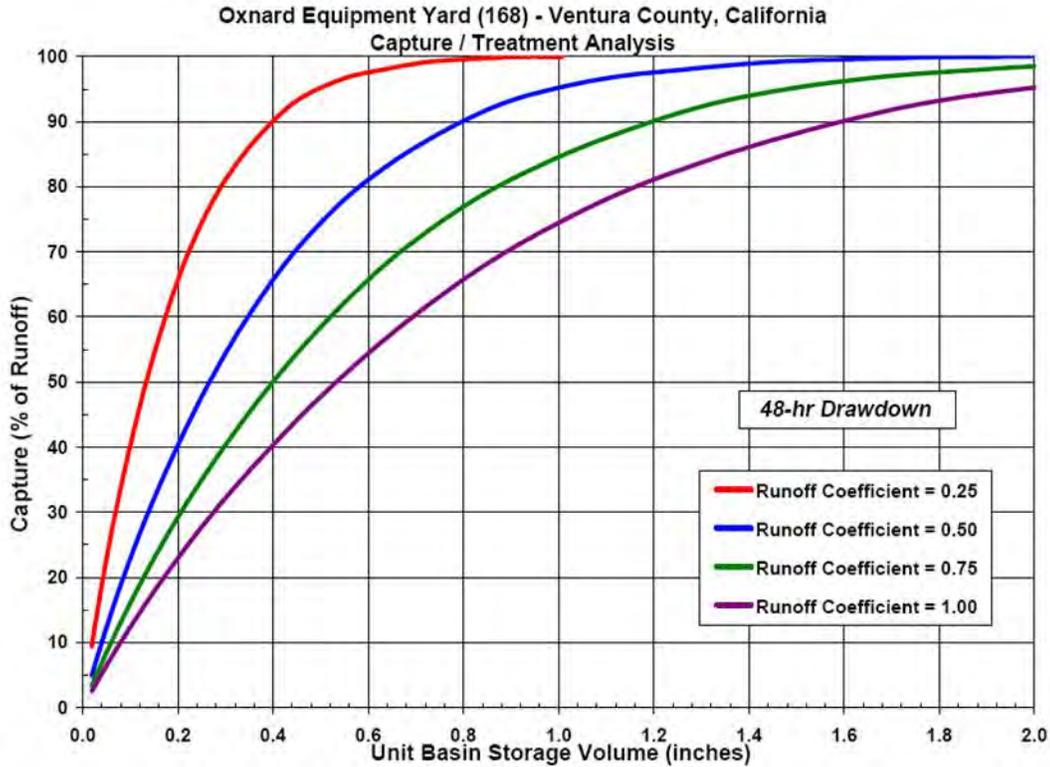

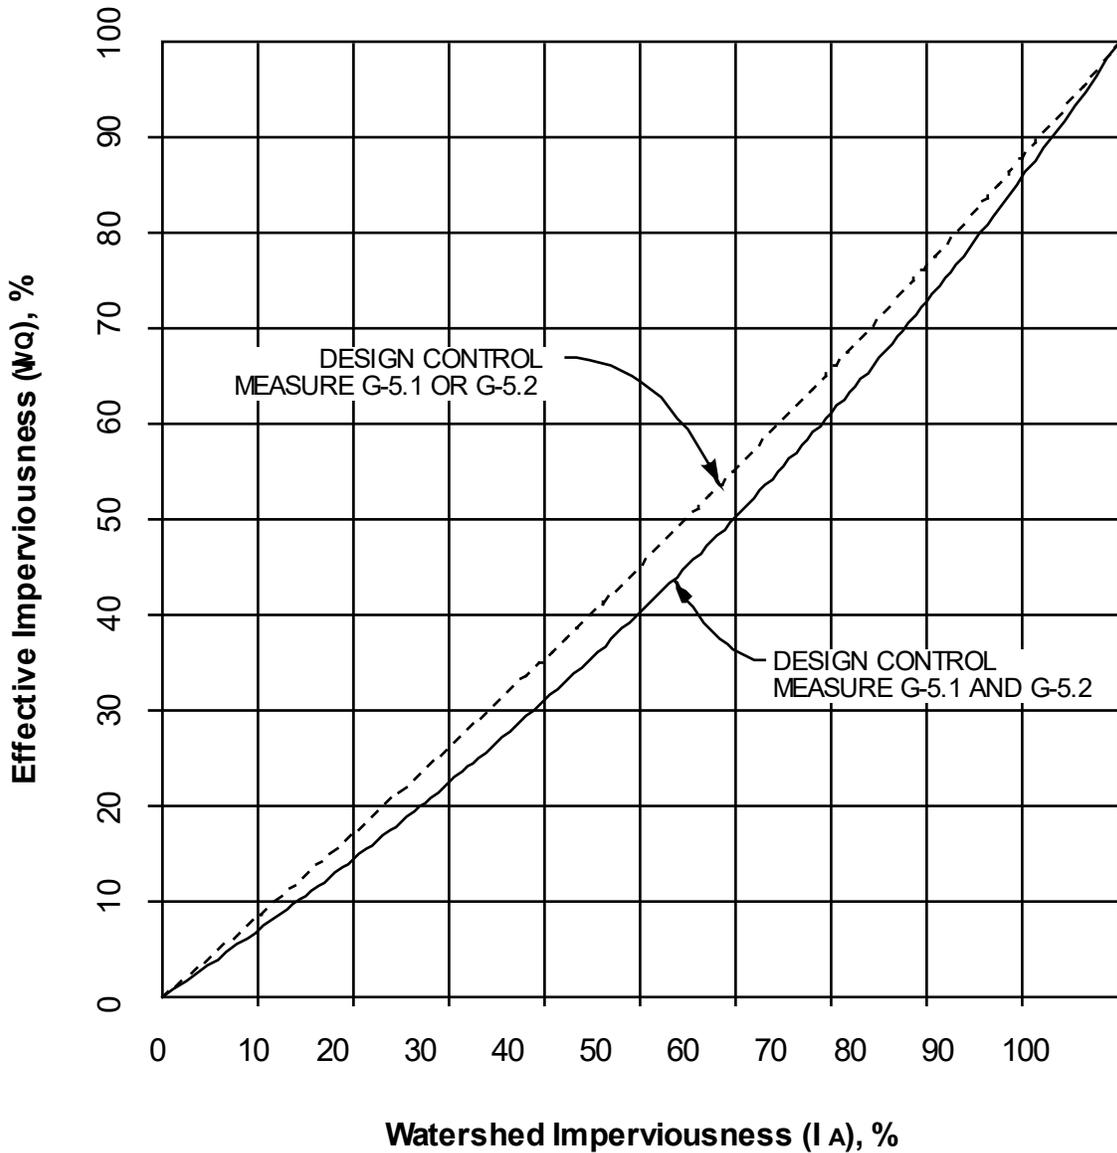

Figure E-1: CASQA 48-hour Drawdown Figure for Oxnard Gauge

This method has been modified for Ventura County. To use this method, follow the calculation procedure below. This refers to Figure E-3.

Ventura County Calculation Procedure

- 1) Review the area draining to the proposed treatment control measure. Determine the effective imperviousness (I_{WQ}) of the drainage area.
- 2) Estimate the total imperviousness (impervious percentage) of the site by the determining the weighted average of individual areas of like imperviousness.
- 3) Enter Figure E-2 along the horizontal axis with the value of total imperviousness calculated in Step 1. Move vertically up Figure E-2 until the appropriate curve (G-5.1 (filter strip) or G-5.2 (vegetated swale) employed individually or G-5.1 and G-5.2 employed together) is intercepted. Move horizontally across Figure E-2 until the vertical axis is intercepted. Read the Effective Imperviousness value along the vertical axis.
- 4) Note that if G-5.1 and/or G-5.2 are implemented on only a portion of the site, the site may be divided and effective imperviousness determined for the portion of the site for which site design controls have been implemented. The resulting effective imperviousness may be combined with total imperviousness of the

remainder of the site to determine a weighted average total imperviousness for the entire site.

G-5.1: TURF BUFFER
G-5.2: GRASS-LINED CHANNEL

ADAPTED FROM URBAN STORM DRAIN CRITERIA MANUAL
VOL. 3-BEST MANAGEMENT PRACTICES,
URBAN DRAINAGE AND FLOOD CONTROL DISTRICT, 11/99

Figure E-2: Effective Imperviousness based on Watershed Imperviousness

- 5) Figure E-3 provides a direct reading of Unit Basin Storage Volumes required for 80% annual capture of runoff for values of “I_{wQ}” determined in Step 1. Enter the horizontal axis of Figure E-3 with the “I_{wQ}” value from Step 1. Move vertically up

Figure E-3 until the appropriate drawdown period line is intercepted. (The design drawdown period specified in the respective Fact Sheet for the proposed treatment control measure.) Move horizontally across Figure E-3 from this point until the vertical axis is intercepted. Read the Unit Basin Storage Volume along the vertical axis.

- 6) Figure E-3 is based on Precipitation Gage 168, Oxnard Airport. This gage has a data record of approximately 40 years of hourly readings and is maintained by Ventura County Flood Control District. Figure E-3 is for use only in the permit area specified in Regional Board Order No. 00-108, NPDES Permit No. CAS004002.
- 7) The SQDV for the proposed treatment control measure is then calculated by multiplying the Unit Basin Storage Volume by the contributing drainage area. Due to the mixed units that result (e.g., acre-inches, acre-feet) it is recommended that the resulting volume be converted to cubic feet for use during design.

Example Stormwater Quality Design Volume Calculation

- 1) Determine the drainage area contributing to control measure, A_t . Example: 10 acres.
- 2) Determine the area of impervious surfaces in the drainage area, A_i . Example: 6.4 acres.
- 3) Calculate the percentage of impervious, $I_A = (A_i / A_t) * 100$

Example:

$$\text{Percent Imperviousness} = (A_i / A_t) * 100 = (6.4 \text{ acres} / 10 \text{ acres}) * 100 = 64\%$$

- 4) Determine Effective Imperviousness using Figure 3-4.
- 5) Determine design drawdown period for proposed control measure.
- 6) Determine the Unit Basin Storage Volume for 80% Annual Capture, V_u using Figure E-3.

$$\text{For } I_{WQ} / 100 = 0.60 \text{ and drawdown} = 40 \text{ hrs, } V_u = 0.64 \text{ in.}$$

- 7) Calculate the volume of the basin, V_b , where

$$V_b = V_u * A_t \quad \text{(Equation E-4)}$$

Where

$$V_b = \text{Volume of basin}$$

V_u = Unit basin storage volume

A_t = Total tributary area

8) $V_b = (0.64 \text{ in})(10 \text{ ac})(\text{ft}/12 \text{ in})(43,560 \text{ ft}^2 / \text{ac}) = 23,232 \text{ ft}^3$.

9) Solution: Size the proposed control measure for 23,232 ft³ and 40-hour drawdown.

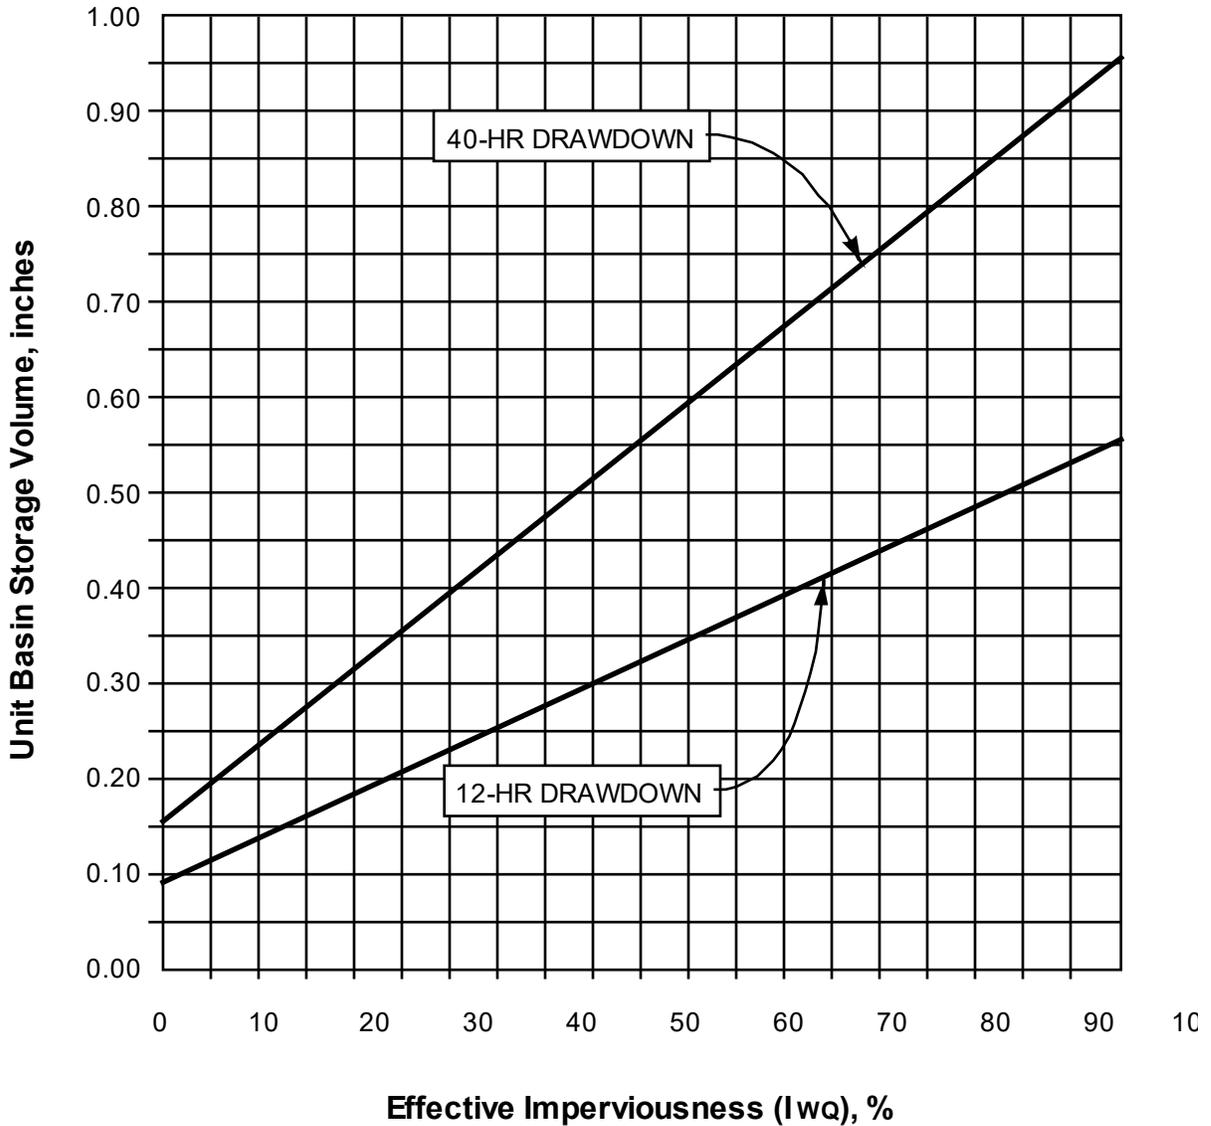

Figure E-3: Unit Basin Storage Volume for Design Volume Method 2

Method 3: 0.75 Inch Design Storm Approach

Equation E-8 can be used to determine the water quality design volume for Method 3.

Calculation Procedure

- 1) Determine the area from which runoff must be retained on-site (A_{retain}) using the method below:

The allowable EIA for a project site can be calculated as follows:

$$EIA_{\text{allowable}} = (A_{\text{project}}) * (\%_{\text{allowable}}) \quad (\text{Equation E-5})$$

Where:

- $EIA_{\text{allowable}}$ = the maximum impervious area from which runoff can be treated and discharged off-site [and not retained on-site] (acres).
- A_{project} = the total project area (acres). “Total project area” for new development and redevelopment projects is defined as the disturbed, developed, and undisturbed portions within the project’s property (or properties) boundary, at the project scale submitted for first approval.
- $\%_{\text{allowable}}$ = ranges from 5 percent to 30 percent, based on a project specific assessment of technical feasibility for retaining runoff and whether the project is located in an existing urban area.

The drainage area from which Project generated runoff must be retained on-site is the total impervious area minus the $EIA_{\text{allowable}}$, which can be calculated as follows:

$$A_{\text{retain}} = TIA - EIA_{\text{allowable}} = (P * A_{\text{project}}) - EIA_{\text{allowable}} \quad (\text{Equation E-6})$$

Where:

- A_{retain} = the drainage area from which runoff must be retained (acres)
- TIA = total impervious area (acres)
- $EIA_{\text{allowable}}$ = the maximum impervious area from which runoff can be treated and discharged off-site [and not retained on-site] (acres).
- P = imperviousness of project area (%) / 100
- A_{project} = the total project area (acres)

Calculation Procedure

- 1) Determine the area from which runoff must be retained on-site (A_{retain}) using method above.
- 2) Determine the runoff coefficient per the following method:

$$C = 0.95 * imp + C_p (1 - imp) \quad \text{(Equation E-7)}$$

Where:

- C = runoff coefficient
- imp = impervious fraction of watershed
- C_p = pervious runoff coefficient, determined using table below

Table E-1: Pervious Runoff Coefficient Based on Ventura Soil Type

Ventura Soil Type (Soil Number)	C_p value
1	0.15
2	0.10
3	0.10
4	0.05
5	0.05
6	0
7	0

- 3) The volume can be calculated using equation E-8 below:

$$SQDV = C * (0.75 / 12) * A_{retain} \quad \text{(Equation E-8)}$$

Where:

- SQDV = the water quality design volume (acre-feet)
- C_{imp} = runoff coefficient, calculated by equation (4) above
- 0.75 = the design rainfall depth (in) [based on sizing method (c)]
- A_{retain} = the drainage area from which runoff must be retained (acres)

Method 4: 80 percent of the average runoff volume using an appropriate public domain continuous flow model

Models that can be used for this calculation include the Storm Water Management Model (SWMM) or Hydrologic Engineering Center – Hydrologic Simulation Program – Fortran (HEC-HSPF)], using the local rainfall record and relevant BMP sizing and design data.

Sizing Method 4 allows for alternative sizing methods to be used as long as the selected method produces a water quality design volume based on historical rainfall records that achieves 80% capture of the average runoff volume. While sizing Methods 2 and 3 are appropriate for low lying areas within Ventura County, continuous simulation (using historical rainfall record) is well suited to sizing BMPs in locations with higher average rainfall. This method is the recommended sizing method for Ventura County, using appropriate local data inputs. For BMP locations at higher elevations, with larger rainfall, Method 1 is also better suited to sizing volume-based BMPs using rainfall representative of the site where the BMP will be located.

Continuous runoff modeling takes a long, uninterrupted record of observed rainfall data and transforms it into a record of runoff data. This is done by use of a set of mathematical algorithms that represent the rainfall-runoff processes. EPA's Stormwater Management Model (U.S. EPA, 2000) (SWMM) is one type of continuous runoff model. The runoff module of SWMM subdivides each drainage area into two inclined planes, one for impervious areas and one for pervious areas. Manning's equation is applied to estimate runoff taking into account rainfall intensity, initial losses, evapotranspiration, and infiltration (for pervious areas). The width and length of each plane is selected based on the drainage area configuration and existing and proposed drainage features. Hourly rainfall data is the primary model input for generating runoff volumes and rates. Additional input data are required to characterize imperviousness, soils, topography, and losses associated with evapotranspiration, infiltration, and initial losses.

Sizing BMPs using this type of alternative should only be conducted by qualified personnel with a thorough understanding of the simulated hydrologic processes and operation of the selected hydrology model.

Methods for Determining the Water Quality Design Flow

Each of the flow-based sizing alternatives is described in detail below.

Method 1: Runoff Produced by 0.2 Inches per Hour Rainfall Intensity

The rainfall analysis for flow-based controls focuses on estimating the design rainfall intensity, which is then converted to a design flow rate using the rational method shown in Equation E-9.

$$SQDF = CiA \quad \text{(Equation E-9)}$$

Where:

SQDF	=	design flow rate (cfs)
C	=	runoff coefficient, calculated with the Ventura County Hydrology Manual method (see Equation E-5) (unitless)
i	=	rainfall intensity (in/hr) (0.2 in/hr)
A	=	watershed area (acres)

Note that 1 acre-in/hr = 1.0083 cfs; this conversion factor can be used with Equation D-9, but is not necessary as the uncertainty for the other parameters is generally well above 0.8%.

Method 2: Runoff Produced by Twice the 85th Percentile Rainfall Intensity

This method is analogous to the rational method used in Method 1, except that twice the historical 85th percentile rainfall intensity for the site location is used for the design rainfall intensity. This method is expected to result in a higher design rainfall intensity and design flow rate compared to Method 1 for most of the rain gages in the District.

Method 3: Runoff Produced by eight percent of the 50-year storm design flow rate

The Stormwater Quality Design Flow (SQDF) is defined to be equal to 8 percent of the peak rate of runoff flow from the 50-year storm as determined using the procedures set forth in the *Hydrology Manual*.

Calculation Procedure

- 1) The Stormwater Quality Design Flow (SQDF) in Ventura County is defined as SQDF
- 2) Calculate the peak rate of flow from the 50-year storm ($Q_{P, 50 \text{ yr.}}$) using the procedures set forth in the *Hydrology Manual* or as directed by the local agency Drainage Master Plan.
- 3) Convert $Q_{P, 50\text{yr}}$ (Step 2) to $Q_{P, \text{SQDF}}$ (Step 1).

$$Q_{P, \text{SQDF}} = 0.1 \times Q_{P, 50\text{yr}} \quad \text{(Equation E-10)}$$

Example Stormwater Quality Design Flow Calculation

The steps below illustrate calculation of SQDF:

- 1) Calculate the peak rate of flow from a 50-year storm.

$$Q_{p, 50 \text{ yr.}} = 10 \text{ cfs from the } \textit{Ventura County Hydrology Manual}$$

- 4) Convert $Q_{p, 50 \text{ yr}}$ (Step 2) to $Q_{p, \text{SQDF}}$ (Step 1)

$$\text{SQDF} = 0.8 \times 10 \text{ cfs} \quad (\text{Equation E-11})$$

$$\text{SQDF} = 0.8 \text{ cfs}$$

Rainfall Analysis Methods

The rainfall analysis methods listed below have the benefits of including the most recent rainfall data. Additionally, if the site is not close to an isohyet map rainfall gauge, these methods may be more accurate due to the variability of rainfall due to changing microclimates caused by elevation and distance from the ocean.

A resource available for obtaining rainfall data in Ventura County is the data collected and compiled by the National Climatic Data Center (NCDC).

There are many NCDC stations within Ventura County that collect or have collected hourly precipitation data. Some of these stations are no longer in operation and others may not have a sufficiently long period of record over which precipitation data has been collected to be of use for properly sizing treatment BMPs. NCDC data may be obtained online at the NCDC website <http://www.ncdc.noaa.gov/oa/ncdc.html>.

Rainfall Analysis Using EPA'S SYNOP Program

US EPA's Synoptic Rainfall Data Analysis Program (SYNOP) aggregates hourly rainfall data into individual storm events and computes event descriptive statistics. The SYNOP program calculates the duration, volume, and intensity for individual storms as well as average annual statistics. Recurrence interval and probability results are also available as output options. The SYNOP program allows the user to screen out storms that are not expected to result in runoff (see step 2 below).

The SYNOP rainfall analysis is conducted to output event-specific data in addition to average annual statistics. The individual storm event data can be ranked to give the 85th percentile storm or averaged to give the mean storm size.

Steps for conducting SYNOP rainfall analysis are as follows:

- 1) Obtain the hourly rainfall data for the gage of interest from the NCDC or other agency.
- 2) Run SYNOP for the available rain gage data. Model input parameters include the inter-event time and a minimum storm event size. The inter-event time specifies the minimum duration in which precipitation does not occur, used to define separate storm events, while the minimum storm event is the depth of precipitation generated by a storm below which runoff generally does not occur. Typically, an inter-event time of 6 hours (USEPA, 1989), and a minimum storm

event size of 0.10 inches are used (i.e., storms of 0.10 inches or less are not considered to produce runoff typically). Model results include event-specific and annual statistics during the period of record analyzed.

- 3) Rank and average the SYNOP storm event output.

E.2 INF-1 Infiltration Basin/ INF-2 Infiltration Trench/ INF-4 Drywell

This worksheet can be used for sizing INF-1 Infiltration Basins, INF-2 Infiltration Trenches, or INF-4 drywells. An infiltration basin is an earthen basin constructed into naturally pervious soils which retains the SQDV and allows the retained runoff to percolate into the underlying native soils over a specified period of time. Infiltration trenches are long, narrow, gravel-filled trenches, often vegetated, that infiltrate stormwater runoff from small drainage areas. Drywells are similar to infiltration trenches, but the geometry and materials are slightly different. A dry well may be either a small excavated pit filled with aggregate or a prefabricated storage chamber or pipe segment, with the depth of the drywell greater than the width.

Sizing Methodology

Infiltration facilities can be sized using one of two methods: a simple sizing method or a routing modeling method. With either method the SQDV volume must be completely infiltrated within 12 to 72 hours (see [Appendix E, Section E.1](#) for a discussion on drawdown time and BMP performance). The simple sizing procedures provided below can be used for either infiltration basins, infiltration trenches (see [INF-2: Infiltration Trench](#)) or drywells (INF-4: Drywell). For the routing modeling method, refer to [VEG-8 Sand Filters](#).

Step 1: Calculate the design volume

Infiltration facilities shall be sized to capture and infiltrate the SQDV volume (see [Section 2](#) and Appendix E) with a 12 - 72 hour drawdown time (see [Appendix E, Section E.1](#)).

Step 2: Determine the Design Percolation Rate

The percolation rate will decline between maintenance cycles as particulates accumulate in the infiltrative layer and the surface becomes occluded. Additionally, monitoring of actual facility performance has shown that the full-scale infiltration rate is far lower than the rate measured by small-scale testing. It is important that adequate conservatism is incorporated in the selection of design percolation rates. For infiltration trenches, the design percolation rate discussed here is the percolation rate of the underlying soils, which will ultimately drive infiltration through the trench, and not the percolation rate of the filter media bed (refer to the “[Geometry and Sizing](#)” section of INF-2 for the recommended composition of the filter media bed for infiltration trenches). See [INF-1: Infiltration Basin](#) for guidance in developing design percolation rate correction factors.

Step 3: Calculate Surface Area

Determine the size of the required infiltrating surface by assuming the SQDV will fill the available ponding depth plus (for infiltration trenches/ drywells with aggregate)

the void spaces within the filter media based on the computed porosity of the media (normally about 32%).

- 1) Determine the maximum depth of runoff that can be infiltrated within the required drain time as follows:

$$d_{\max} = \frac{P_{\text{design}} t}{12} \quad \text{(Equation E-12)}$$

Where:

d_{\max} = the maximum depth of water that can be infiltrated within the required drain time (ft)

P_{design} = design percolation rate of underlying soils (in/hr)

t = required drain time (hrs)

- 2) Choose the ponding depth (d_p) and/or trench depth (d_t) such that:

$$d_{\max} \geq d_p \quad \text{For Infiltration Basins} \quad \text{(Equation E-13)}$$

$$d_{\max} \geq n_t d_t + d_p \quad \text{For Infiltration Trenches or aggregate-filled Drywells} \quad \text{(Equation E-14)}$$

Where:

d_{\max} = the maximum depth of water that can be infiltrated within the required drain time (ft)

d_p = ponding depth (ft)

n_t = trench/drywell fill aggregate porosity (unitless)

d_t = depth of trench/drywell filter media (ft)

- 3) Calculate infiltrating surface area (filter bottom area) required:

$$A = \frac{SQDV}{((TP_{\text{design}} / 12) + d_p)} \quad \text{For Infiltration Basins} \quad \text{(Equation E-15)}$$

$$A = \frac{SQDV}{((TP_{\text{design}} / 12) + n_t d_t + d_p)} \quad \text{For Infiltration Trenches or aggregate-filled Drywells} \quad \text{(Equation E-16)}$$

Where:

$SQDV$ = stormwater quality design volume (ft³)

n_t	=	trench fill aggregate porosity (unitless)
P_{design}	=	design percolation rate (in/hr)
d_p	=	ponding depth (ft)
d_t	=	depth of trench filter media (ft)
T	=	fill time (time to fill to max ponding depth with water) (hrs) [use 2 hours for most designs]

Step 4: Size the forebay (applies to infiltration basins and trenches)

Infiltration facilities require pre-treatment to reduce sediment load into the basin. If a separate pre-treatment unit is not used, a forebay should be constructed for the facility. If a forebay is used, all inlets must enter the sediment forebay. The sediment forebay must be sized to 25% of the basin volume. The forebay must have interior slopes no steeper than 4:1.

- 1) Calculate the volume of the sediment forebay:

$$V_{forebay} = 0.25 \times SQDV \quad \text{(Equation E-17)}$$

Where:

$V_{forebay}$ = Volume of sediment forebay

$SQDV$ = Stormwater Quality Design Volume of Infiltration Basin

- 2) Select the depth of forebay, $d_{forebay}$. This is recommended to be...

- 3) Determine bottom surface area of forebay:

$$A_{forebay} = \frac{V_{forebay}}{d_{forebay}} \quad \text{(Equation E-18)}$$

Where:

$A_{forebay}$ = Bottom surface area of forebay

$V_{forebay}$ = Volume of forebay

$d_{forebay}$ = Depth of forebay

- 4) Size forebay outlet pipe. Pipe must 8 inches in diameter, minimum, and must be sized such that the forebay drains completely within 10 minutes.

Step 5: Provide conveyance capacity for filter clogging

The infiltration facility should be placed off-line, but an emergency overflow must still be provided in the event the filter becomes clogged. Spillway and overflow

structures should be designed in accordance with applicable standards of the Ventura County Flood Control District or local jurisdiction.

Sizing Worksheet

Step 1: Determine water quality design volume	
1-1. Enter Project area (acres), $A_{project}$	$A_{project} =$ acres
1-2. Enter the maximum allowable percent of the Project area that may be effective impervious area (%) (refer to permit), ranges from 5-30%, $\%_{allowable}$	$\%_{allowable} =$ %
1-3. Determine the maximum allowable effective impervious area (acres), $EIA_{allowable} = (A_{project}) * (\%_{allowable})$	$EIA_{allowable} =$ acres
1-4. Enter Project impervious fraction, Imp (e.g. 60% = 0.60)	$Imp =$
1-5. Determine the Project Total Impervious area (acres), $TIA = A_{project} * Imp$	$TIA =$ acres
1-6. Determine the total area from which runoff must be retained (acres), $A_{retain} = TIA - EIA_{allowable}$	$A_{retain} =$ acres
1-7. Determine pervious runoff coefficient using Table E-1, C_p	$C_p =$
1-8. Calculate runoff coefficient, $C = 0.95 * imp + C_p (1 - imp)$	$C =$
1-9. Enter design rainfall depth of the storm (in), P_i	$P_i =$ in
1-10. Calculate rainfall depth (ft), $P = P_i / 12$	$P =$ ft
1-11. Calculate water quality design volume (ft ³), $SQDV = 43560 * C * P * A_{retain}$	$SQDV =$ ft ³
Step 2: Determine the design percolation rate	
2-1. Enter measured soil percolation rate (in/hr, 0.5 in/hr min.), $P_{measured}$	$P_{measured} =$ in/hr
2-2. Determine percolation rate correction factor, S_A based on suitability assessment (see Section 6 INF-1)	$S_A =$

2-3. Determine percolation rate correction factor, S_B based on design (see Section 6 INF-1)	$S_b =$
2-4. Calculate combined safety factor, $S = S_A \times S_b$	$S =$
2-5. Calculate the design percolation rate (in/hr), $P_{design} = P_{measured}/S$	$P_{design} =$ in/hr
Step 3: Calculate the surface area	
3-1. Enter required drain time(hours,72 hrs max.), t	$t =$ hrs
3-2. Calculate max. depth of runoff that can be infiltrated within the t (ft), $d_{max} = P_{design} t/12$	$d_{max} =$ ft
3-3. For basins, select ponding depth (ft), d_p , such that $d_p \leq d_{max}$	$d_p =$ ft
3-4. For trenches, enter trench fill aggregate porosity, n_t	$n_t =$
3-5. For trenches, enter depth of trench fill (ft), d_t	$d_t =$ ft
3-5. For trenches, select ponding depth d_p such that $d_p \leq d_{max} - n_t d_t$	$d_p =$ ft
3-6. Enter the time to fill infiltration basin or trench with water (Use 2 hours for most designs), T	$T =$ hrs
3-7. Calculate infiltrating surface area for infiltration basin (ft ²): $A_b = SQDV/(T P_{design} /12+d_p)$ OR Calculate infiltrating surface area for infiltration trenches or aggregate- filled drywells (ft ²): $A_t = SQDV/(T P_{design} /12+n_t d_t+d_p)$	$A_b =$ ft ² $A_t =$ ft ²
Step 4: Size the forebay (infiltration basins or trenches)	
If a separate pre-treatment unit is designed for the infiltration facility, skip to Step 5. If not, continue through 4-1 through 4-4.	

<p>4-1. Calculate the volume of the forebay (ft³), $V_{\text{forebay}} = 0.25 * SQDV$</p>	<p>$V_{\text{forebay}} =$ ft³</p>
<p>4-2. Determine forebay depth (ft), d_{forebay}</p>	<p>$d_{\text{forebay}} =$ ft</p>
<p>4-3. Calculate forebay bottom surface area (ft²), $A_{\text{forebay}} = V_{\text{forebay}} / d_{\text{forebay}}$</p>	<p>$A_{\text{forebay}} =$ ft²</p>
<p>4-4. Provide outlet pipe such that the forebay drains to the infiltration facility within 10 minutes.</p>	
<p>Step 5: Provide conveyance capacity for filter clogging</p>	
<p>5-1. The infiltration facility should be placed off-line, but an emergency overflow must still be provided in the event the filter becomes clogged. Design emergency overflow in accordance with applicable standards of the Ventura County Flood Control District or local jurisdiction.</p>	

Design Example

Step 1: Determine water quality design volume

For this design example, a 10-acre residential development with a 60% total impervious area is considered to drain to an infiltration basin. The 85th percentile storm event for the project location is 0.75 inches.

Step 1: Determine water quality design volume	
1-1. Enter Project area (acres), $A_{project}$	$A = 10$ acres
1-2. Enter the maximum allowable percent of the Project area that may be effective impervious area (%) (refer to permit), ranges from 5-30%, $\%_{allowable}$	$\%_{allowable} = 5$
1-3. Determine the maximum allowable effective impervious area (acres), $EIA_{allowable} = (A_{project}) * (\%_{allowable})$	$EIA_{allowable} = 0.5$ acres
1-4. Enter Project impervious fraction, Imp (e.g. 60% = 0.60)	$Imp = 0.6$
1-5. Determine the Project Total Impervious area (acres), $TIA = A_{project} * Imp$	$TIA = 6$ acres
1-6. Determine the total area from which runoff must be retained (acres), $A_{retain} = TIA - EIA_{allowable}$	$A_{retain} = 5.5$ acres
1-7. Determine pervious runoff coefficient using Table E-1, C_p	$C_p = 0.05$
1-8. Calculate runoff coefficient, $C = 0.95 * imp + C_p (1 - imp)$	$C = 0.59$
1-9. Enter design rainfall depth of the storm (in), P_i	$P_i = 0.75$ in
1-10. Calculate rainfall depth (ft), $P = P_i / 12$	$P = 0.06$ ft
1-11. Calculate water quality design volume (ft ³), $SQDV = 43560 * C * P * A_{retain}$	$SQDV = 8,500$ ft ³

Step 2: Calculate Design Infiltration Rate

Infiltration facilities require a minimum soil infiltration rate of 0.5 in/hr. If the rate exceeds 2.4 in/hr as in this example, then the runoff should be fully treated in an upstream BMP prior to infiltration to protect the groundwater quality.

Step 2: Determine the design percolation rate	
2-1. Enter measured soil percolation rate (0.5 in/hr min.), $P_{measured}$	$P_{measured} = 4.0 \text{ in/hr}$
2-2. Determine percolation rate correction factor, S_A , based on suitability assessment (see Section 6 INF-1)	$S_A = 3$
2-3. Determine percolation rate correction factor, S_B , based on design (see Section 6 INF-1)	$S_b = 3$
2-4. Calculate combined safety factor, $S = S_A \times S_b$	$S = 9$
2-5. Calculate the design percolation rate, $P_{design} = P_{measured}/S$	$P_{design} = 0.44 \text{ in/hr}$

Step 3: Determine Facility Size

The size of the infiltrating surface is determined by assuming the SQDV will fill the available ponding depth (plus the void spaces of the computed porosity (usually about 32%) of the gravel in the trench).

Step 3: Calculate the surface area	
3-1. Enter drawdown time (72 hrs max.), t_d	$t = 72 \text{ hrs}$
3-2. Calculate max. depth of runoff that can be infiltrated within the t , $d_{max} = P_{design} t/12$	$d_{max} = 2.4 \text{ ft}$
3-3. Enter trench fill aggregate porosity, n_t	$n_t = 0.32$
3-4. Enter depth of trench fill, d_t	$d_t = 4 \text{ ft}$
3-5. Select trench ponding depth d_p such that $d_p \leq d_{max} - n_t d_t$	$d_p = 1.1 \text{ ft}$
3-6. Enter the time to fill infiltration basin or trench with water (Use 2 hours for most designs), T	$T = 2 \text{ hrs}$

3-7. Calculate infiltrating surface area for infiltration basin: $A_b = SQDV / (T P_{design} / 12 + d_p)$	$A_b = 7,250 \text{ ft}^2$
---	----------------------------

Step 4: Size the Forebay

A sediment forebay will be provided for this example as there is no separate pre-treatment unit provided.

Step 4: Size the forebay	
4-1. Calculate the volume of the forebay, $V_{forebay} = 0.25 * SQDV$	$V_{forebay} = 2,100 \text{ ft}^3$
4-2. Determine forebay depth, $d_{forebay}$	$d_{forebay} = 3 \text{ ft}$
4-3. Calculate forebay bottom surface area, $A_{forebay} = V_{forebay} / d_{forebay}$	$A_{forebay} = 700 \text{ ft}^2$
4-4. Provide outlet pipe such that the forebay drains to the infiltration facility within 10 minutes.	

Step 5: Provide Conveyance Capacity for Flows Higher than Qwq

The infiltration facility should be placed off-line, but an emergency overflow for flows greater than the peak design storm must still be provided in the event the filter becomes clogged. Design emergency overflow in accordance with applicable standards of the Ventura County Flood Control District or local jurisdiction.

E.3 INF-3 Bioretention

Sizing Methodology

Bioretention areas can be sized using one of two methods: a simple sizing method or a routing method. The simple sizing procedure is summarized below. Continuous simulation modeling, routing spreadsheets, and/or other forms of routing modeling that incorporate rainfall-runoff relationships and infiltrative (flow) capacities of bioretention may be used to size facilities. Alternative sizing methodologies should be prepared with good engineering practices. For the routing modeling method, refer to the Sand Filter design guidance (FILT-1). A bioretention sizing worksheet and example are provided in this appendix. Planter boxes are sized the same as bioretention areas with underdrains using parameters appropriate for planter boxes.

With either method, the runoff entering the facility must completely drain the ponding area within 48 hours, and runoff must be completely infiltrated within 96 hours. Bioretention is to be sized, with or without underdrains, such that the SQDV will fill the available ponding depth, the void spaces in the planting soil, and the optional gravel layer below the media.

Step 1: Determine the stormwater quality design volume (SQDV)

Bioretention areas should be sized to capture and treat the water quality design volume (see Section E.1).

Step 2: Determine the Design Percolation Rate

The percolation rate will decline between maintenance cycles as particulates accumulate in the infiltrative layer and the surface becomes occluded. Additionally, monitoring of actual facility performance has shown that the full-scale infiltration rate is far lower than the rate measured by small-scale testing. It is important that adequate conservatism is incorporated in the selection of design percolation rates. For infiltrating bioretention facilities, the design percolation rate discussed here is the percolation rate of the underlying soils, which will drive infiltration through the facility. See [INF-3: Bioretention](#) for guidance in developing design percolation rate correction factors.

Step 3: Calculate the bioretention surface area

- 1) Determine the maximum depth of surface ponding that can be infiltrated within the required surface drain time:

$$d_{\max} = \frac{P_{\text{design}} \times t_{\text{ponding}}}{12 \frac{\text{in}}{\text{ft}}}$$

Where:

- $t_{ponding}$ = required drain time of surface ponding (48 hrs)
- P_{design} = design percolation rate of underlying soils (in/hr) (see Step 2, above)
- d_{max} = the maximum depth of surface ponding water that can be infiltrated within the required drain time (ft)

2) Choose surface ponding depth (d_p) such that:

$$d_p \leq d_{max} \quad \text{(Equation E-19)}$$

Where:

- d_p = selected surface ponding depth (ft)
- d_{max} = the maximum depth of water that can be infiltrated within the required drain time (ft)

3) Choose thickness(es) of amended media and aggregate layer(s) and calculate total effective storage depth of the bioretention area as follows:

$$d_{effective} \leq d_p + n_{media}^* l_{media} + n_{gravel} l_{gravel} \quad \text{(Equation E-20)}$$

Where:

- $d_{effective}$ = total equivalent depth of water stored in bioretention area (ft)
- d_p = surface ponding depth (ft)
- n_{media}^* = available porosity of amended soil media (ft/ft), approximately 0.25 ft/ft accounting for antecedent moisture conditions
- l_{media} = thickness of amended soil media layer (ft)
- n_{gravel} = porosity of optional gravel layer (ft/ft), approximately 0.30 ft/ft
- l_{gravel} = thickness of optional gravel layer (ft)

4) Check that entire effective depth (surface plus subsurface storage) infiltrates in no greater than 96 hours as follows:

$$t_{total} = \frac{d_{effective}}{P_{design}} \times 12 \frac{in}{ft} \leq 96 \text{ hr} \quad \text{(Equation E-21)}$$

Where:

$d_{effective}$ = total equivalent depth of water stored in bioretention area (ft)
 P_{design} = design percolation rate of underlying soils (in/hr) (see Step 2, above)

If $t_{total} > 96$ hrs, then reduce surface ponding depth and/or amended media thickness and/or gravel thickness and return to Step [A].

If $t_{total} \leq 96$ hrs, then proceed to Step [E].

5) Calculate required infiltrating surface area (filter bottom area):

$$A_{req} = \frac{SQDV}{d_{effective}} \quad \text{(Equation E-22)}$$

Where:

$SQDV$ = stormwater quality design volume (ft³)

Step 4: Calculate the bioretention total footprint

Calculate total footprint required by including a buffer for side slopes and freeboard; A_{req} is measured at the as the filter bottom area (toe of side slopes).

Sizing Worksheet

Step 1: Determine water quality design volume	
1-1. Enter Project area (acres), $A_{project}$	$A_{project} =$ acres
1-2. Enter the maximum allowable percent of the Project area that may be effective impervious area (%) (refer to permit), ranges from 5-30%, $\%_{allowable}$	$\%_{allowable} =$ %
1-3. Determine the maximum allowable effective impervious area (acres), $EIA_{allowable} = (A_{project}) * (\%_{allowable})$	$EIA_{allowable} =$ acres
1-4. Enter Project impervious fraction, Imp (e.g. 60% = 0.60)	$Imp =$
1-5. Determine the Project Total Impervious area (acres), $TIA = A_{project} * Imp$	$TIA =$ acres
1-6. Determine the total area from which runoff must be retained (acres), $A_{retain} = TIA - EIA_{allowable}$	$A_{retain} =$ acres
1-7. Determine pervious runoff coefficient using Table E-1, C_p	$C_p =$
1-8. Calculate runoff coefficient, $C = 0.95 * imp + C_p (1 - imp)$	$C =$
1-9. Enter design rainfall depth of the storm (in), P_i	$P_i =$ in
1-10. Calculate rainfall depth (ft), $P = P_i / 12$	$P =$ ft
1-11. Calculate water quality design volume (ft ³), $SQDV = 43560 * C * P * A_{retain}$	$SQDV =$ ft ³
Step 2: Determine the design percolation rate	
2-1. Enter measured soil percolation rate (in/hr) (0.5 in/hr minimum), $P_{measured}$	$P_{measured} =$ in/hr
2-2. Determine percolation rate correction factor, S_A based on suitability assessment (see Section 6 INF-3)	$S_A =$

2-3. Determine percolation rate correction factor, S_B based on design (see Section 6 INF-3)	$S_B =$
2-4. Calculate combined safety factor, $S = S_A \times S_b$	$S =$
2-5. Calculate the design percolation rate (in/hr), $P_{design} = P_{measured}/S$	$P_{design} =$ in/hr
Step 3: Calculate Bioretention Infiltrating surface area	
3-1. Enter water quality design volume (ft ³), $SQDV$	$SQDV =$ ft ³
3-2. Enter design percolation rate (in/hr), P_{design}	$P_{design} =$ in/hr
3-3 Enter the required drain time (48 hours), $t_{ponding}$	$t_{ponding} =$ hours
3-3. Calculate the maximum depth of surface ponding that can be infiltrated within the required drain time (ft): $d_{max} = (P_{design} \times t_{ponding})/12$	$d_{max} =$ ft
3-4. Select surface ponding depth (ft), d_p , such that $d_p \leq d_{max}$	$d_p =$ ft
3-5. Select thickness of amended media (ft, 2 feet minimum, 3 preferred), l_{media}	$l_{media} =$ ft
3-6. Enter porosity of amended media (roughly 25% or 0.25 ft/ft), n_{media}	$n_{media} =$ ft/ft
3-7. Select thickness of optional gravel layer (ft), l_{gravel}	$l_{gravel} =$ ft
3-8. Enter porosity of gravel (roughly 30% or 0.3 ft/ft), n_{gravel}	$n_{gravel} =$ ft/ft
3-9. Calculate the total effective storage depth of bioretention facility (ft): $d_{effective} \leq (d_p + n_{media}l_{media} + n_{gravel}l_{gravel})$	$d_{effective} =$ ft

<p>3-10. Check that the entire effective depth infiltrates in required drainage time, 96 hours:</p> $t_{total} = (d_{effective}/P_{design}) \times 12$ <p>If $t_{total} > 96$ hours, reduce surface ponding depth and/or amended media thickness and/or gravel thickness and return to 3-4.</p> <p>If $t_{total} \leq 96$ hours, proceed to 3-11.</p>	$t_{total} = \quad \text{hours}$
<p>3-11. Calculate the required infiltrating surface area (ft²):</p> $A_{req} = SQDV/d_{effective}$	$A_{req} = \quad \text{ft}^2$
<p>Step 4: Calculate Bioretention Area Total Footprint</p>	
<p>4-1. Calculate total footprint required by including a buffer for side slopes and freeboard (ft²) [A_{req} is measured at the as the filter bottom area (toe of side slopes)], A_{tot}</p>	$A_{tot} = \quad \text{ft}^2$

Design Example

Bioretention areas have several components that allow the pretreatment, spreading, filtration, collection and discharge of the incoming flows.

Step 1: Determine water quality design volume

For this design example, a 10-acre site with soil type 4 and 60% total impervious area is considered. The 85th percentile storm event for the project location is 0.75 inches.

Step 1: Determine water quality design volume	
1-1. Enter Project area (acres), $A_{project}$	$A_{project} = 10$ acres
1-2. Enter the maximum allowable percent of the Project area that may be effective impervious area (%) (refer to permit), ranges from 5-30%, $\%_{allowable}$	$\%_{allowable} = 5$
1-3. Determine the maximum allowable effective impervious area (acres), $EIA_{allowable} = (A_{project}) * (\%_{allowable})$	$EIA_{allowable} = 0.5$ acres
1-4. Enter Project impervious fraction, Imp (e.g. 60% = 0.60)	$Imp = 0.6$
1-5. Determine the Project Total Impervious area (acres), $TIA = A_{project} * Imp$	$TIA = 6$ acres
1-6. Determine the total area from which runoff must be retained (acres), $A_{retain} = TIA - EIA_{allowable}$	$A_{retain} = 5.5$ acres
1-7. Determine pervious runoff coefficient using <u>Table E-1</u> , C_p	$C_p = 0.05$
1-8. Calculate runoff coefficient, $C = 0.95 * imp + C_p (1 - imp)$	$C = 0.59$
1-9. Enter design rainfall depth of the storm (in), P_i	$P_i = 0.75$ in
1-10. Calculate rainfall depth (ft), $P = P_i / 12$	$P = 0.06$ ft
1-11. Calculate water quality design volume (ft ³), $SQDV = 43560 * C * P * A_{retain}$	$SQDV = 8,500$ ft ³

Step 2: Determine the design percolation rate

For this design example, a native soil percolation rate of 1.5 in/hr is assumed.

Step 2: Determine the design percolation rate	
2-1. Enter measured soil percolation rate (in/hr, 0.5 in/hr minimum), $P_{measured}$	$P_{measured} = 4.0$ in/hr
2-2. Determine percolation rate correction factor, S_A , based on suitability assessment (see Section 6 INF-1)	$S_A = 3$
2-3. Determine percolation rate correction factor, S_B , based on design (see Section 6 INF-1)	$S_b = 3$
2-4. Calculate combined safety factor, $S = S_A \times S_b$	$S = 9$
2-5. Calculate the design percolation rate (in/hr), $P_{design} = P_{measured}/S$	$P_{design} = 0.44$ in/hr

Step 3: Determine bioretention/ planter box area footprint

A bioretention area is designed with two components: (1) temporary storage reservoir to store runoff, and (2) a plant mix filter bed (planting soil mixed with sand content = 70%) through which the stored runoff must percolate to obtain treatment.

Step 3: Calculate bioretention/planter box surface area	
3-1. Enter water quality design volume (ft ³), $SQDV$	$SQDV = 8,500$ ft ³
3-2. Enter design percolation rate (in/hr), P_{design}	$P_{design} = 0.375$ in/hr
3-3 Enter the required drain time (48 hours), $t_{ponding}$	$t_{ponding} = 48$ hours
3-3. Calculate the maximum depth of surface ponding (ft) that can be infiltrated within the required drain time (48 hours): $d_{max} = (P_{design} \times t_{ponding})/12$	$d_{max} = 1.5$ ft
3-4. Select surface ponding depth d_p such that $d_p \leq d_{max}$	$d_p = 1.5$ ft
3-5. Select thickness of amended media (2 feet minimum, 3 preferred), l_{media}	$l_{media} = 3$ ft

Step 3: Calculate bioretention/planter box surface area	
3-6. Enter porosity of amended media (roughly 25% or 0.25 ft/ft), n_{media}	$n_{media} = 0.25 \text{ ft/ft}$
3-7. Select thickness of optional gravel layer (ft), l_{gravel}	$l_{gravel} = 1 \text{ ft}$
3-8. Enter porosity of gravel (roughly 30% or 0.3 ft/ft), n_{gravel}	$n_{gravel} = 0.3 \text{ ft/ft}$
3-9. Calculate the total effective storage depth of bioretention facility (ft): $d_{effective} \leq (d_p + n_{media}l_{media} + n_{gravel}l_{gravel})$	$d_{effective} = 2.6 \text{ ft}$
3-10. Check that the entire effective depth infiltrates in required drainage time, 96 hours: $t_{total} = (d_{effective}/P_{design}) \times 12$ If $t_{total} > 96$ hours, reduce surface ponding depth and/or amended media thickness and/or gravel thickness and return to 3-4. If $t_{total} \leq 96$ hours, proceed to 3-11.	$t_{total} = 82 \text{ hours}$
3-11. Calculate the required infiltrating surface area (ft ²), $A_{req} = SQDV/d_{effective}$	$A_{req} = 3,300 \text{ ft}^2$

Step 4: Calculate Bioretention Area Total Footprint

For this design example, a natural-shaped bioretention area is assumed, with 3:1 side slopes. To calculate the total footprint, the side slopes would be added to the design geometry.

E.4 INF-5 Permeable Pavement

Sizing Methodology

Permeable pavement (including the base layers) shall be designed to drain in less than 72 hours. The basis for this is that soils must be allowed to dry out periodically in order to restore hydraulic capacity; this is essential in order to receive flows from subsequent storms, maintain infiltration rates, maintain adequate sub soil oxygen levels for healthy soil biota, and to provide proper soil conditions for biodegradation and retention of pollutants.

Permeable pavement must be built and designed by a licensed civil engineer in accordance with Ventura County roadway and pavement specifications.

Step 1: Calculate the design volume

Permeable pavement shall be sized to capture and treat the stormwater quality design volume, SQDV (see [Section 2](#) and Appendix E).

Step 2: Determine the Design Percolation Rate

The percolation rate will decline between maintenance cycles as particulates accumulate in the infiltrative layer and the surface becomes occluded. Additionally, monitoring of actual facility performance has shown that the full-scale infiltration rate is far lower than the rate measured by small-scale testing. It is important that adequate conservatism is incorporated in the selection of design percolation rates. For infiltrating bioretention facilities, the design percolation rate discussed here is the percolation rate of the underlying soils, which will drive infiltration through the facility. See INF-5: Permeable Pavement for guidance in developing design percolation rate correction factors.

Step 3: Determine gravel drainage layer depth

Permeable pavement (including the base layers) shall be designed to drain in less than 72 hours. The basis for this is that soils must be allowed to dry out periodically in order to restore hydraulic capacity to receive flows from subsequent storms, maintain infiltration rates, maintain adequate sub soil oxygen levels for healthy soil biota, and to provide proper soil conditions for biodegradation and retention of pollutants.

- 1) Calculate the maximum depth of runoff, d_{max} , that can be infiltrated within the drawdown time:

$$d_{max} = \frac{P_{design} \cdot t}{12} \quad \text{(Equation E-23)}$$

Where:

- d_{max} = maximum depth that can be infiltrated (ft)
 P_{design} = design percolation rate of underlying soils (in/hr) (see Step 2, above)
 t = drawdown time (72 hrs maximum) (hr)

- 1) Select the gravel drainage layer depth, l , such that:

$$d_{max} \geq n \times l \quad \text{(Equation E-24)}$$

Where:

- d_{max} = maximum depth that can be infiltrated (ft) (see 1) above)
 n = gravel drainage layer porosity(unitless) (generally about 32% or 0.32 for gravel)
 l = gravel drainage layer depth (ft)

Step 4: Determine infiltrating surface area

- 1) Calculate infiltrating surface area for permeable pavement, A :

$$A = \frac{SQDV}{\frac{TP_{design}}{12} + nl} \quad \text{(Equation E-25)}$$

Where:

- P_{design} = design percolation rate of underlying soils (in/hr) (see Step 2, above)
 n = gravel drainage layer porosity(unitless)[about 32% or 0.32 for gravel]
 l = depth of gravel drainage layer (ft)
 T = time to fill the gravel drainage layer with water (use 2 hours for most designs) (hr)

Step 5: Provide conveyance capacity for clogging

The permeable pavement must have an emergency overflow for storm events greater than the design and in the event the permeable pavement becomes clogged. See INF-5 Permeable Pavement for overflow details.

Sizing Worksheet

Step 1: Determine water quality design volume	
1-1. Enter Project area (acres), $A_{project}$	$A_{project} =$ acres
1-2. Enter the maximum allowable percent of the Project area that may be effective impervious area (%) (refer to permit), ranges from 5-30%, $\%_{allowable}$	$\%_{allowable}$ %
1-3. Determine the maximum allowable effective impervious area (acres), $EIA_{allowable} = (A_{project}) * (\%_{allowable})$	$EIA_{allowable} =$ acres
1-4. Enter Project impervious fraction, Imp (e.g. 60% = 0.60)	$Imp =$
1-5. Determine the Project Total Impervious area (acres), $TIA = A_{project} * Imp$	$TIA =$ acres
1-6. Determine the total area from which runoff must be retained (acres), $A_{retain} = TIA - EIA_{allowable}$	$A_{retain} =$ acres
1-7. Determine pervious runoff coefficient using <u>Table E-1</u> , C_p	$C_p =$
1-8. Calculate runoff coefficient, $C = 0.95 * imp + C_p (1 - imp)$	$C =$
1-9. Enter design rainfall depth of the storm (in), P_i	$P_i =$ in
1-10. Calculate rainfall depth (ft), $P = P_i / 12$	$P =$ ft
1-11. Calculate water quality design volume (ft ³), $SQDV = 43560 * C * P * A_{retain}$	$SQDV =$ ft ³
Step 2: Determine the design percolation rate	
2-1. Enter measured soil percolation rate (0.5 in/hr minimum), $P_{measured}$	$P_{measured} =$ in/hr
2-2. Determine percolation rate correction factor, S_A based on suitability assessment (see Section 6 INF-5)	$S_A =$

Step 2: Determine the design percolation rate	
2-3. Determine percolation rate correction factor, S_B based on design (see Section 6 INF-5)	$S_B =$
2-4. Calculate combined safety factor, $S = S_A \times S_b$	$S =$
2-5. Calculate the design percolation rate (in/hr), $P_{design} = P_{measured}/S$	$P_{design} =$ in/hr
Step 3: Determine the Gravel Drainage Layer Depth	
3-1. Enter drawdown time (hours, 72 hrs max.), t	$t =$ hours
3-2. Calculate max. depth of runoff (ft) that can be infiltrated within the t , $d_{max} = P_{design}t/12$	$d_{max} =$ ft
3-3. Enter the gravel drainage layer porosity, n (typically 32% or 0.32 for gravel)	$n =$
3-4. Select the gravel drainage layer depth (ft) such that $d_{max} \geq n \times l$	$l =$ ft
Step 4: Determine infiltrating surface area	
4-1. Enter gravel drainage layer porosity, n	$n =$
4-2. Enter depth of gravel drainage layer (ft), l	$l =$ ft
4-3. Enter the time to fill the gravel drainage layer with water (Use 2 hours for most designs), T	$T =$ hrs
4-4. Calculate infiltrating surface area (ft ³): $A = SQDV / ((TP_{design}/12) + nl)$	$A =$ ft ²
Step 5: Provide conveyance capacity for clogging	
5-1. The permeable pavement must have an emergency overflow for storm events greater than the design and in the event the permeable pavement becomes clogged.	

Design Example

Step 1: Determine Water Quality Design Volume

For this design example, a 10-acre residential development with a 60% total impervious area is considered. The 85th percentile storm event for the project location is 0.75 inches.

Step 1: Determine Water Quality Design Volume	
1-1. Enter Project area (acres), $A_{project}$	$A = 10$ acres
1-2. Enter the maximum allowable percent of the Project area that may be effective impervious area (%) (refer to permit), ranges from 5-30%, $\%_{allowable}$	$\%_{allowable} = 5$
1-3. Determine the maximum allowable effective impervious area (acres), $EIA_{allowable} = (A_{project}) * (\%_{allowable})$	$EIA_{allowable} = 0.5$ acres
1-4. Enter Project impervious fraction, Imp (e.g. 60% = 0.60)	$Imp = 0.6$
1-5. Determine the Project Total Impervious area (acres), $TIA = A_{project} * Imp$	$TIA = 6$ acres
1-6. Determine the total area from which runoff must be retained (acres), $A_{retain} = TIA - EIA_{allowable}$	$A_{retain} = 5.5$ acres
1-7. Determine pervious runoff coefficient using Table E-1 , C_p	$C_p = 0.05$
1-8. Calculate runoff coefficient, $C = 0.95 * imp + C_p (1 - imp)$	$C = 0.59$
1-9. Enter design rainfall depth of the storm (in), P_i	$P_i = 0.75$ in
1-10. Calculate rainfall depth (ft), $P = P_i / 12$	$P = 0.06$ ft
1-11. Calculate water quality design volume (ft ³), $SQDV = 43560 * C * P * A_{retain}$	$SQDV = 8,500$ ft ³

Step 2: Calculate Design Percolation Rate

Permeable pavement with no underdrain requires a minimum soil infiltration rate of 0.5 in/hr. For this design example, a native soil percolation rate of 1.5 in/hr is assumed.

Step 2: Determine the design percolation rate	
2-1. Enter measured soil percolation rate (0.5 in/hr min.), $P_{measured}$	$P_{measured} = 4.0 \text{ in/hr}$
2-2. Determine percolation rate correction factor, S_A , based on suitability assessment (see Section 6 INF-1)	$S_A = 3$
2-3. Determine percolation rate correction factor, S_B , based on design (see Section 6 INF-1)	$S_b = 3$
2-4. Calculate combined safety factor, $S = S_A \times S_b$	$S = 9$
2-5. Calculate the design percolation rate (in/hr), $P_{design} = P_{measured}/S$	$P_{design} = 0.44 \text{ in/hr}$

Step 3: Determine maximum depth that can be infiltrated

Based on the design infiltration rate and the max drawdown, determine the maximum depth that can be infiltrated within the time constraints.

Step 3: Determine maximum depth that can be infiltrated	
3-1. Enter drawdown time (72 hrs max.), t	$t = 72 \text{ hrs}$
3-2. Calculate max. depth of runoff (ft) that can be infiltrated within the t , $d_{max} = P_{design}t/12$	$d_{max} = 2.6 \text{ ft}$
3-3. Enter the gravel drainage layer porosity, n (typically 32% or 0.32 for gravel)	$n = 0.32$
3-4. Select the gravel drainage layer depth (ft) such that $d_{max} \geq n \times l$	$l = 8 \text{ ft}$

Step 4: Determine the infiltrating surface area (pavement area)

Using the depth calculated in Step 3, the required infiltrating surface area of the pavement can be calculated.

Step 4: Determine the infiltrating surface area	
4-1. Enter gravel drainage layer porosity, n	$n = 0.32$
4-2. Enter depth of gravel drainage layer (ft), l	$l = 8 \text{ ft}$
4-3. Enter the time to fill the gravel drainage layer with water (Use 2 hours for most designs), T	$T = 2 \text{ hrs}$
4-4. Calculate infiltrating surface area (ft ³): $A = SQDV / (TP_{design} / 12) + n * l$	$A = 1,630 \text{ ft}^2$

Step 5: Provide conveyance capacity for clogging

The permeable pavement must have an emergency overflow for storm events greater than the design and in the event the permeable pavement becomes clogged.

E.5 VEG-1 Bioretention/VEG-2 Planter Box

Sizing Methodology

Bioretention areas can be sized using one of two methods: a simple sizing method or a routing method. The simple sizing procedure is summarized below. Continuous simulation modeling, routing spreadsheets, and/or other forms of routing modeling that incorporate rainfall-runoff relationships and infiltrative (flow) capacities of bioretention may be used to size facilities. Alternative sizing methodologies should be prepared with good engineering practices. For the routing modeling method, refer to the Sand Filter design guidance (FILT-1). A bioretention sizing worksheet and example are provided in this appendix. Planter boxes are sized the same as bioretention areas with underdrains using parameters appropriate for planter boxes.

With either method, the runoff entering the facility must completely drain the ponding area within 48 hours, and runoff must be completely infiltrated within 96 hours. Bioretention is to be sized, with or without underdrains, such that the SQDV will fill the available ponding depth, the void spaces in the planting soil, and the optional aggregate layer.

Step 1: Determine the stormwater quality design volume (SQDV)

Bioretention areas should be sized to capture and treat the water quality design volume (see Section E.1).

Step 2: Determine the Design Percolation Rate

Sizing is based on the design saturated hydraulic conductivity (K_{sat}) of the amended soil layer. A target K_{sat} of 5 inches per hour is recommended for newly installed non-proprietary amended soil media. The media K_{sat} will decline between maintenance cycles as the surface becomes occluded and particulates accumulate in the amended soil layer. A factor of safety of 2.0 should be applied such that the resulting recommended design percolation rate is 2.5 inches per hour. This value should be used for sizing unless sufficient rationale is provided to justify a higher design percolation rate.

Step 3: Calculate the bioretention or planter box surface area

Determine the size of the required infiltrating surface by assuming the SQDV will fill the available ponding depth plus the void spaces in the media, based on the computed porosity of the filter media and optional aggregate layer.

- 1) Select a surface ponding depth (d_p) that satisfies geometric criteria and congruent with the constraints of the site. Selecting a deeper ponding depth (18 inches maximum) generally yields a smaller footprint, however requires greater consideration for public safety and energy dissipation.

- 2) Compute time for selected ponding depth to filter through media:

$$t_{ponding} = \frac{d_p}{K_{design}} 12 \frac{in}{ft} \leq 48 \text{ hours} \quad (\text{Equation E-26})$$

Where:

- $t_{ponding}$ = required drain time of surface ponding (48 hrs)
 d_p = selected surface ponding water depth (ft)
 K_{design} = design saturated hydraulic conductivity (in/hr) (see Step 2, above)

If $t_{ponding}$ exceeds 48 hours, return to (1) and reduce surface ponding or increase media K_{design} . Otherwise, proceed to next step.

Note: In nearly all cases, $t_{ponding}$ will not approach 48 hours unless a low K_{design} is specified.

- 3) Compute depth of water that may be considered to be filtered during the design storm event as follows:

$$d_{filtered} = \text{Minimum} \left[\frac{K_{design} \times T_{routing}}{12 \frac{in}{ft}}, \frac{d_p}{2} \right] \quad (\text{Equation E-27}),$$

Where:

- $d_{filtered}$ = depth of water that may be considered to be filtered during the design storm event (ft) for routing calculations; this value should not exceed half of the surface ponding depth (d_p)
 K_{design} = design saturated hydraulic conductivity (in/hr) (see Step 2, above)
 $T_{routing}$ = storm duration that may be assumed for routing calculations; this should be assumed to be **3 hours** unless rationale for an alternative assumption is provided
 d_p = selected surface ponding water depth (ft)

- 4) Calculate required infiltrating surface area (filter bottom area):

$$A_{req} = \frac{SQDV}{d_p + d_{filtered}} \quad (\text{Equation E-28})$$

Where:

A_{req}	=	required area at bottom of filter area (ft ²); does not account for side slopes and freeboard
$SQDV$	=	stormwater quality design volume (ft ³)
d_p	=	selected surface ponding water depth (ft)
$d_{filtered}$	=	depth of water that can be considered to be filtered during the design storm event (ft) for routing calculations (See previous step)

Step 4: Calculate the bioretention total footprint

Calculate total footprint required by including a buffer for side slopes and freeboard; A_{req} is measured at the filter bottom area (toe of side slopes).

Step 5: Calculate underdrain system capacity

Underdrains are required for planter boxes and bioretention with underdrains. For guidance on sizing, refer to step 5 of the worksheet below. Alternatively, the Ventura County Hydrology Manual can be used for pipe sizing guidance.

Sizing Worksheet

Step 1: Determine water quality design volume	
1-1. Enter Project area (acres), $A_{project}$	$A_{project} =$ acres
1-2. Enter the maximum allowable percent of the Project area that may be effective impervious area (refer to permit), ranges from 5-30%, $\%_{allowable}$	$\%_{allowable}$ %
1-3. Determine the maximum allowed effective impervious area (ac), $EIA_{allowable} = (A_{project}) * (\%_{allowable})$	$EIA_{allowable} =$ acres
1-4. Enter Project impervious fraction, Imp (e.g. 60% = 0.60)	$Imp =$
1-5. Determine the Project Total Impervious area (acres), $TIA = A_{project} * Imp$	$TIA =$ acres
1-6. Determine the total area from which runoff must be retained (acres), $A_{retain} = TIA - EIA_{allowable}$	$A_{retain} =$ acres
1-7. Determine pervious runoff coefficient using Table E-1 , C_p	$C_p =$
1-8. Calculate runoff coefficient, $C = 0.95 * imp + C_p (1 - imp)$	$C =$
1-9. Enter design rainfall depth of the storm (in), P_i	$P_i =$ in
1-10. Calculate rainfall depth (ft), $P = P_i / 12$	$P =$ ft
1-11. Calculate water quality design volume (ft ³), $SQDV = 43560 * C * P * A_{retain}$	$SQDV =$ ft ³
Step 2: Determine the design percolation rate	
2-1. Enter the design saturated hydraulic conductivity of the amended filter media (2.5 in/hr recommended rate), K_{design}	$K_{design} =$ in/hr

Step 3: Calculate Bioretention/Planter Box surface area		
3-1. Enter water quality design volume (ft ³), $SQDV$	$SQDV =$	ft ³
3-2. Enter design saturated hydraulic conductivity (in/hr), K_{design}	$K_{design} =$	in/hr
3-3. Enter ponding depth (max 1.5 ft for Bioretention, 1 ft for Planter Box) above area, d_p	$d_p =$	ft
3-4. Calculate the drawdown time for the ponded water to filter through media (hours), $t_{ponding} = (d_p / K_{design}) \times 12$	$t_{ponding} =$	hrs
3-5. Enter the storm duration for routing calculations (use 3 hours unless there is rationale for an alternative), $T_{routing}$	$T_{routing} =$	hrs
3-6. Calculate depth of water (ft) filtered by using the following two equations: $d_{filtered,1} = (K_{design} \times T_{routing}) / 12$ $d_{filtered,2} = d_p / 2$	$d_{filtered,1} =$ $d_{filtered,2} =$	ft ft
3-7 Enter the resultant depth (ft) (the lesser of the two calculated above), $d_{filtered}$	$d_{filtered} =$	ft
3-8. Calculate the infiltrating surface area as follows (ft ²): $A_{req} = SQDV / (d_p + d_{filtered})$	$A_{req} =$	ft ²
Step 4: Calculate Bioretention Area Total Footprint		
4-1. Calculate total footprint required by including a buffer for side slopes and freeboard (ft ²) [A_{req} is measured at the as the filter bottom area (toe of side slopes)], A_{tot}	$A_{tot} =$	ft ²
Step 5: Calculate Underdrain System Capacity		
To calculate the underdrain system capacity, continue through steps 5-1 to 5-7.		

Step 5: Calculate Underdrain System Capacity	
5-1. Calculated filtered flow rate to be conveyed by the longitudinal drain pipe, $Q_f = K_{design} A_{req}/43,200$	$Q_f =$ cfs
5-2. Enter minimum slope for energy gradient, S_e	$S_e =$
5-3. Enter Hazen-Williams coefficient for plastic, C_{HW}	$C_{HW} =$
5-4. Enter pipe diameter (min 6 inches), D	$D =$ in
5-5. Calculate pipe hydraulic radius (ft), $R_h = D/48$	$R_h =$ ft
5-6. Calculate velocity at the outlet of the pipe (ft/s), $V_p = 1.318 C_{HW} R_h^{0.63} S_e^{0.54}$	$V_p =$ ft/s
5-7. Calculate pipe capacity (cfs), $Q_{cap} = 0.25 \pi (D/12)^2 V_p$	$Q_{cap} =$ cfs

Design Example

Bioretention areas have several components that allow the pretreatment, spreading, filtration, collection and discharge of the incoming flows.

Step 1: Determine water quality design volume

For this design example, a 10-acre residential development with a 60% total impervious area is considered. The 85th percentile storm event for the project location is 0.75 inches.

Step 1: Determine Water Quality Design Volume	
1-1. Enter drainage area, A	A = 10 acres
1-2. Enter the maximum allowable percent of the Project area that may be effective impervious area (refer to permit), ranges from 5-30%, $\%_{allowable}$	$\%_{allowable} = 5$
1-3. Determine the maximum allowed effective impervious area, $EIA_{allowable} = (A_{project}) * (\%_{allowable})$	$EIA_{allowable} = 0.5$ acres
1-4. Enter Project impervious fraction, Imp (e.g. 60% = 0.60)	$Imp = 0.6$
1-5. Determine the Project Total Impervious area, $TIA = A_{project} * Imp$	$TIA = 6$ acres
1-6. Determine the total area from which runoff must be retained, $A_{retain} = TIA - EIA_{allowable}$	$A_{retain} = 5.5$ acres
1-7. Determine pervious runoff coefficient using <u>Table E-1</u> , C_p	$C_p = 0.05$
1-8. Calculate runoff coefficient, $C = 0.95 * imp + C_p (1 - imp)$	$C = 0.59$
1-9. Enter design rainfall depth of the storm, P_i (in)	$P_i = 0.75$ in
1-10. Calculate rainfall depth, $P = P_i / 12$	$P = 0.06$ ft
1-11. Calculate water quality design volume, $SQDV = 43560 * P * A_{retain} * C$	$SQDV = 8,500$ ft ³

Step 2: Determine the design percolation rate

For this design example, the recommended amended filter hydraulic conductivity is used, 2.5 in/hr.

Step 2: Determine the design percolation rate	
2-1. Enter the design saturated hydraulic conductivity of the amended filter media (2.5 in/hr recommended rate), K_{design}	$K_{design} = 2.5$ in/hr

Step 3: Determine bioretention/ planter box area footprint

A bioretention area is designed with two components: (1) temporary storage reservoir to store runoff, and (2) a plant mix filter bed (planting soil mixed with sand content = 70%) through which the stored runoff must percolate to obtain treatment.

Step 3: Calculate Bioretention/Planter Box surface area	
3-1. Enter water quality design volume (ft ³), $SQDV$	$SQDV = 8,500$ ac-ft
3-2. Enter design saturated hydraulic conductivity (in/hr), K_{design}	$K_{design} = 2.5$ in/hr
3-3. Enter ponding depth (max 1.5 ft for Bioretention, 1 ft for Planter Box) above area, d_p	$d_p = 1.5$ ft
3-4. Calculate the drawdown time for the ponded water to filter through media (hours), $t_{ponding} = (d_p/K_{design}) \times 12$	$t_{ponding} = 7.2$ hrs
3-5. Enter the storm duration for routing calculations (use 3 hours unless there is rationale for an alternative), $T_{routing}$	$T_{routing} = 3$ hrs
3-6. Calculate depth of water (ft) filtered by using the minimum of the following two equations: $d_{filtered,1} = (K_{design} \times T_{routing})/12$ $d_{filtered,2} = d_p / 2$	$d_{filtered,1} = 0.63$ ft $d_{filtered,2} = 0.75$ ft
3-7 Enter the resultant depth (the minimum of the two calculated above), $d_{filtered}$	$d_{filtered} = 0.63$ ft
3-8. Calculate the infiltrating surface area as follows (ft ²): $A_{req} = SQDV/(d_p + d_{filtered})$	$A_{req} = 4,000$ ft ²

Step 4: Calculate Bioretention Area Total Footprint

For this design example, a natural-shaped bioretention area is assumed, with 3:1 side slopes. To calculate the total footprint, the side slopes would be added to the design geometry.

Step 5: Calculate filter longitudinal underdrain collection pipe

All underdrain pipes must be 6 inches or greater in diameter to facilitate cleaning.

Step 5: Calculate underdrain system (required for planter box)	
To calculate the underdrain system capacity, continue through steps 5-1 to 5-7. If you don't need to calculate the underdrain capacity, skip this step.	
5-1. Calculated filtered flow rate to be conveyed by the longitudinal drain pipe (cfs), $Q_f = K_{design} A_{req}/43,200$	$Q_f = 0.085$ cfs
5-2. Enter minimum slope for energy gradient, S_e	$S_e = 0.005$
5-3. Enter Hazen-Williams coefficient for plastic, C_{HW}	$C_{HW} = 140$
5-4. Enter pipe diameter (min 6 in), D	$D = 6$ in
5-5. Calculate pipe hydraulic radius (ft), $R_h = D/48$	$R_h = 0.13$ ft
5-6. Calculate velocity at the outlet of the pipe (ft/s), $V_p = 1.318C_{HW}R_h^{0.63}S_e^{0.54}$	$V_p = 2.9$ ft/s
5-7. Calculate pipe capacity (cfs), $Q_{cap} = 0.25\pi(D/12)^2V_p$	$Q_{cap} = 0.57$ cfs

E.6 VEG-3 Vegetated Swale

Sizing Methodology

The flow capacity of a vegetated swale is a function of the longitudinal slope (parallel to flow), the resistance to flow (i.e. Manning's roughness), and the cross sectional area. The cross section is normally approximately trapezoidal and the area is a function of the bottom width and side slopes. The flow capacity of vegetated swales should be such that the design water quality flow rate will not exceed a flow depth of 2/3 the height of the vegetation within the swale or 4 inches at the water quality design flow rate. Once design criteria have been selected, the resulting flow depth for the design water quality design flow rate is checked. If the depth restriction is exceeded, swale parameters (e.g. longitudinal slope, width) are adjusted to reduce the flow depth.

Procedures for sizing vegetated swales are summarized below. A vegetated swale sizing worksheet and example are also provided.

Step 1: Select design flows

The swale sizing is based on the stormwater quality design flow SQDF (see [Section E.1](#)).

Step 2: Calculate swale bottom width

The swale bottom width is calculated based on Manning's equation for open-channel flow. This equation can be used to calculate discharges as follows:

$$Q = \frac{1.49AR^{0.67}S^{0.5}}{n}$$

(Equation E-29)

Where:

Q	=	flow rate (cfs)
n	=	Manning's roughness coefficient (unitless)
A	=	cross-sectional area of flow (ft ²)
R	=	hydraulic radius (ft) = area divided by wetted perimeter
S	=	longitudinal slope (ft/ft)

For shallow flow depths in swales, channel side slopes are ignored in the calculation of bottom width. Use the following equation (a simplified form of Manning's formula) to estimate the swale bottom width:

$$b = \frac{SQDF * n_{wq}}{1.49y^{0.67}s^{0.5}} \quad (\text{Equation E-30})$$

Where:

b	=	bottom width of swale (ft)
$SQDF$	=	stormwater quality design flow (cfs)
n_{wq}	=	Manning's roughness coefficient for shallow flow conditions = 0.2 (unitless)
y	=	design flow depth (ft)
s	=	longitudinal slope (along direction of flow) (ft/ft)

Proceed to Step 3 if the bottom width is calculated to be between 2 and 10 feet. A minimum 2-foot bottom width is required. Therefore, if the calculated bottom width is less than 2 feet, increase the width to 2 feet and recalculate the design flow depth y using the Equation 4-13, where Q_{wq} , n_{wq} , and s are the same values as used above, but $b = 2$ feet.

The maximum allowable bottom width is 10 feet; therefore if the calculated bottom width exceeds 10 feet, then one of the following steps is necessary to reduce the design bottom width:

- 1) Increase the longitudinal slope (s) to a maximum of 6 feet in 100 feet (0.06 feet per foot).
- 2) Increase the design flow depth (y) to a maximum of 4 inches.
- 3) Place a divider lengthwise along the swale bottom (Figure 3-1) at least three-quarters of the swale length (beginning at the inlet), without compromising the design flow depth and swale lateral slope requirements. Swale width can be increased to an absolute maximum of 16 feet if a divider is provided.

Step 3: Determine design flow velocity

To calculate the design flow velocity through the swale, use the flow continuity equation:

$$V_{wq} = SQDF/A_{wq} \quad (\text{Equation E-31})$$

Where:

V_{wq}	=	design flow velocity (fps)
$SQDF$	=	stormwater quality design flow (cfs)

$$A_{wq} = by + Zy^2 = \text{cross-sectional area (ft}^2\text{) of flow at design depth, where } Z = \text{side slope length per unit height (e.g., } Z = 3 \text{ if side slopes are 3H:1V)}$$

If the design flow velocity exceeds 1 foot per second, go back to Step 2 and modify one or more of the design parameters (longitudinal slope, bottom width, or flow depth) to reduce the design flow velocity to 1 foot per second or less. If the design flow velocity is calculated to be less than 1 foot per second, proceed to Step 4. *Note: It is desirable to have the design velocity as low as possible, both to improve treatment effectiveness and to reduce swale length requirements.*

Step 4: Calculate swale length

Use the following equation to determine the necessary swale length to achieve a hydraulic residence time of at least 7 minutes:

$$L = 60t_{hr}V_{wq} \quad \text{(Equation E-32)}$$

Where:

L = minimum allowable swale length (ft)

t_{hr} = hydraulic residence time (min)

V_{wq} = design flow velocity (fps)

The minimum swale length is 100 feet; therefore, if the swale length is calculated to be less than 100 feet, increase the length to a minimum of 100 feet, leaving the bottom width unchanged. If a larger swale can be fitted on the site, consider using a greater length to increase the hydraulic residence time and improve the swale's pollutant removal capability. If the calculated length is too long for the site, or if it would cause layout problems, such as encroachment into shaded areas, proceed to Step 5 to further modify the layout. If the swale length can be accommodated on the site (meandering may help), proceed to Step 6.

Step 5: Adjust swale layout to fit on site

If the swale length calculated in Step 4 is too long for the site, the length can be reduced (to a minimum of 100 feet) by increasing the bottom width up to a maximum of 16 feet, as long as the 10 minute retention time is retained. However, the length cannot be increased in order to reduce the bottom width because Manning's depth-velocity-flow rate relationships would not be preserved. If the bottom width is increased to greater than 10 feet, a low flow dividing berm is needed to split the swale cross section in half to prevent channelization.

Length can be adjusted by calculating the top area of the swale and providing an equivalent top area with the adjusted dimensions.

- 1) Calculate the swale treatment top area based on the swale length calculated in Step 4:

$$A_{top} = (b_i + b_{slope})L_i \quad \text{(Equation E-33)}$$

Where:

A_{top} = top area (ft²) at the design treatment depth

b_i = bottom width (ft) calculated in Step 2

b_{slope} = the additional top width (ft) above the side slope for the design water depth (for 3:1 side slopes and a 4-inch water depth, $b_{slope} = 2$ feet)

L_i = initial length (ft) calculated in Step 4

- 2) Use the swale top area and a reduced swale length L_f to increase the bottom width, using the following equation:

$$L_f = A_{top} / (b_f + b_{slope}) \quad \text{(Equation E-34)}$$

Where:

L_f = reduced swale length (ft)

b_f = increased bottom width (ft).

- 3) Recalculate V_{wq} according to Step 3 using the revised cross-sectional area A_{wq} based on the increased bottom width b_f . Revise the design as necessary if the design flow velocity exceeds 1 foot per second.
- 4) Recalculate to assure that the 10 minute retention time is retained.

Step 6: Provide conveyance capacity for flows higher than SQDF

Vegetated swales may be designed as flow-through channels that convey flows higher than the water quality design flow rate, or they may be designed to incorporate a high-flow bypass upstream of the swale inlet. A high-flow bypass usually results in a smaller swale size. If a high-flow bypass is provided, this step is not needed. If no high-flow bypass is provided, proceed with the procedure below. Flow splitter structure design is described in Appendix G.

- 1) Check the swale size to determine whether the swale can convey the flood control design storm peak flows (Refer to the Ventura County Hydrology Manual, 2006).
- 2) The peak flow velocity of the flood control design storm (e.g., flood control design storm – see Ventura County Hydrology Manual, 2006)) must be less than 3.0 feet per second. If this velocity exceeds 3.0 feet per second, return to Step 2 and

increase the bottom width or flatten the longitudinal slope as necessary to reduce the flood control design storm peak flow velocity to 3.0 feet per second or less. If the longitudinal slope is flattened, the swale bottom width must be recalculated (Step 2) and must meet all design criteria.

Sizing Worksheet

Step 1: Determine water quality design flow	
1-1. Enter Project area (acres), $A_{project}$	$A_{design} =$ acres
1-2. Enter impervious fraction, Imp (e.g. 60% = 0.60)	$Imp =$
1-3. Determine pervious runoff coefficient using Table E-1, C_p	$C_p =$
1-4. Calculate runoff coefficient, $C = 0.95*imp + C_p (1-imp)$	$C =$
1-5. Enter design rainfall intensity (in/hr), i	$i =$ in/hr
1-6. Calculate water quality design flow (cfs), $SQDF = CiA$	$SQDF =$ cfs
Step 2: Calculate swale bottom width	
2-1. Enter water quality design flow (cfs), $SQDF$	$SQDF =$ cfs
2-2. Enter Manning's roughness coefficient for shallow flow conditions, $n_{wq} = 0.2$	$n_{wq} =$
2-3. Calculate design flow depth (ft), y	$y =$ ft
2-4. Enter longitudinal slope (ft/ft) (along direction of flow), s	$s =$ ft/ft
2-5. Calculate bottom width of swale (ft), $b = (SQDF*n_{wq})/(1.49y^{0.67}s^{0.5})$	$b =$ ft
2-6. If b is between 2 and 10 feet, go to Step 3	
2-7. If b is less than 2 ft, assume $b = 2$ ft and recalculate flow depth, $y = ((SQDF*n_{wq})/(2.98 s^{0.5}))^{1.49}$	$y =$ ft

<p>2-8. If b is greater than 10 ft, one of the following design adjustments must be made (recalculate variables as necessary):</p> <ul style="list-style-type: none"> • Increase the longitudinal slope to a maximum of 0.06 ft/ft. • Increase the design flow depth to a maximum of 4 in (0.33 ft). • Place a divider lengthwise along the swale bottom (Figure 3-1) at least three-quarters of the swale length (beginning at the inlet). Swale width can be increased to an absolute maximum of 16 feet if a divider is provided. 	
Step 3: Determine design flow velocity	
<p>3-1. Enter side slope length per unit height (H:V) (e.g. 3 if side slopes are 3H :1V), Z</p>	$Z =$
<p>3-2. Enter bottom width of swale (ft), b</p>	$b =$ ft
<p>3-3. Enter design flow depth (ft), y</p>	$y =$ ft
<p>3-4. Calculate the cross-sectional area of flow at design depth (ft²),</p> $A_{wq} = by + Zy^2$	$A_{wq} =$ ft ²
<p>3-5. Calculate design flow velocity (ft/s), $V_{wq} = SQDF / A_{wq}$</p>	$V_{wq} =$ ft/s
<p>3-6. If the design flow velocity exceeds 1 ft/s, go back to Step 2 and change one or more of the design parameters to reduce the design flow velocity. If design flow velocity is less than 1 ft/s, proceed to Step 4.</p>	
Step 4: Calculate swale length	
<p>4-1. Enter hydraulic residence time (minutes, minimum 7 min), t_{hr}</p>	$t_{hr} =$ min
<p>4-2. Calculate swale length (ft), $L = 60t_{hr}V_{wq}$</p>	$L =$ ft

Step 4: Calculate swale length	
<p>4-3. If L is too long for the site, proceed to Step 5 to adjust the swale layout</p> <p>If L is greater than 100 ft and will fit within the constraints of the site, skip to Step 6</p> <p>If L is less than 100 ft, increase the length to a minimum of 100 ft, leaving the bottom width unchanged, and skip to Step 6</p>	
Step 5: Adjust swale layout to fit within site constraints	
5-1. Enter the bottom width calculated in Step 2 (ft), $b_i = b$	$b_i =$ ft
5-2. Enter design flow depth (ft), y	$y =$ ft
5-3. Enter the swale side slope ratio (H:V), Z	$Z =$ ft:ft
5-4. Enter the additional top width above the side slope for the design water depth (ft), $b_{slope} = 2Zy$	$b_{slope} =$ ft
5-5. Enter the initial length calculated in Step 4 (ft), $L_i = L$	$L_i =$ ft
5-6. Calculate the top area at the design treatment depth (ft ²), $A_{top} = (b_i + b_{slope}) \times L_i$	$A_{top} =$ ft ²
5-7. Choose a reduced swale length based on site constraints (ft), L_f	$L_f =$ ft
5-8. Calculate the increased bottom width (ft), $b_f = (A_{top}/L_f) - b_{slope}$	$b_f =$ ft
5-9. Recalculate the cross-sectional area of flow at design depth (ft ²), $A_{wq,f} = b_f y + Zy^2$	$A_{wq,f} =$ ft ²
5-10. Recalculate design flow velocity (ft/s), $V_{wq} = SQDF / A_{wq}$ Revise design as necessary if design flow velocity exceeds 1 ft/s.	$V_{wq} =$ ft/s

<p>5-11. Recalculate the hydraulic residence time (min),</p> $t_{hr} = L_f / (60V_{wq})$ <p>Ensure that t_{hr} is greater or equal to 10 minutes.</p>	<p>$t_{hr} =$ min</p>
<p>5-12. When V_{wq} and t_{hr} are recalculated to meet requirements, proceed to Step 6.</p>	
<p>Step 6: Provide conveyance capacity for flows higher than SQDF (if swale is on-line)</p>	
<p>6-1. If the swale already includes a high-flow bypass to convey flows higher than the water quality design flow rate, skip this step and verify that all parameters meet design requirements to complete sizing</p>	
<p>6-2. If swale does not include a high-flow bypass, determine that the swale can convey flood control design storm peak flows. Calculate the capital peak flow velocity per Ventura County requirements (ft/s), V_p</p>	<p>$V_p =$ ft/s</p>
<p>6-3. If $V_p > 3.0$ feet per second, return to Step 2 and increase the bottom width or flatten the longitudinal slope as necessary to reduce the flood control design storm peak flow velocity to 3.0 feet per second or less. If the longitudinal slope is flattened, the swale bottom width must be recalculated (Step 2) and must meet all design criteria.</p>	

Design Example

Step 1: Determine water quality design Flow

For this design example, a 10-acre site with Type 4 soil and 60% total imperviousness is considered. Flow-based sizing Method 1 is assumed. Therefore, the design intensity is 0.2 in/hr.

Step 1: Determine water quality design flow	
1-1. Enter Project area (acres), $A_{project}$	$A = 10$ acres
1-2. Enter impervious fraction, Imp (e.g. 60% = 0.60)	$Imp = 0.60$
1-3. Determine pervious runoff coefficient using Table E-1, C_p	$C_p = 0.05$
1-4. Calculate runoff coefficient, $C = 0.95 * imp + C_p (1 - imp)$	$C = 0.59$
1-5. Enter design rainfall intensity (in/hr), i	$i = 0.2$ in/hr
1-6. Calculate water quality design flow (cfs), $SQDF = CiA$	$SQDF = 1.18$ cfs

Step 2: Calculate Swale Bottom Width

The swale bottom width is calculated based on Manning's equation. The grass height in the swale will be maintained at 6-inches. The design flow depth is assumed to be 2/3 of the grass height, or 4 inches (0.33 ft). The default Manning's roughness coefficient is assumed appropriate for expected vegetation density and design depth. The slope was assumed to be 0.04.

Step 2: Calculate swale bottom width	
2-1. Enter water quality design flow (cfs), $SQDF$	$SQDF = 1.18$ cfs
2-2. Enter Manning's roughness coefficient for shallow flow conditions, $n_{wq} = 0.2$	$n_{wq} = 0.2$
2-3. Calculate design flow depth (ft), y	$y = 0.33$ ft
2-4. Enter longitudinal slope (along direction of flow) (ft/ft), s	$s = 0.04$ ft/ft
2-5. Calculate bottom width of swale (ft),	$b = 5.0$ ft

Step 2: Calculate swale bottom width	
$b = Q_{wq}n_{wq} / 1.49y^{0.67}S^{0.5}$	
2-6. If b is between 2 and 10 feet, go to Step 3	
2-7. If b is less than 2 ft, assume $b = 2$ ft and recalculate flow depth, $y = (Q_{wq}n_{wq} / 2.98S^{0.5})^{1.49}$	Not applicable
2-8. If b is greater than 10 ft, one of the following design adjustments must be made (and recalculate as necessary): Increase the longitudinal slope to a maximum of 0.06 ft/ft. Increase the design flow depth to a maximum of 4 in (0.33 ft). Place a divider lengthwise along the swale bottom (Figure 3-1) at least three-quarters of the swale length (beginning at the inlet). Swale width can be increased to an absolute maximum of 16 feet if a divider is provided.	Not applicable

Step 3: Determine Design Flow Velocity

For this design example, it is assumed the side slopes will be designed as 3H: 1V, so $Z = 3$.

Step 3: Determine design flow velocity	
3-1. Enter side slope length per unit height (H:V) (e.g. 3 if side slopes are 3H :1V), Z	$Z = 3$
3-2. Enter bottom width of swale (ft), b	$b = 5.0 \text{ ft}$
3-3. Enter design flow depth (ft), y	$y = 0.33 \text{ ft}$
3-4. Calculate the cross-sectional area of flow at design depth (ft ²), $A_{wq} = by + Zy^2$	$A_{wq} = 2.0 \text{ ft}^2$
3-5. Calculate design flow velocity (ft/s), $V_{wq} = SQDF / A_{wq}$	$V_{wq} = 0.59 \text{ ft/s}$
3-6. If the design flow exceeds 1 ft/s, go back to Step 2 and change one or more of the design parameters to reduce the design flow velocity. If design flow velocity is less than 1 ft/s, proceed to Step 4.	

Step 4: Calculate Swale Length

Using the design flow velocity and a minimum residence time of 7 minutes, the length of the swale is calculated as follows. The swale length must be a minimum of 100 ft.

Step 4: Calculate swale length	
4-1. Enter hydraulic residence time (min 7 min), t_{hr} (min)	$t_{hr} = 10 \text{ min}$
4-2. Calculate swale length, $L = 60t_{hr}V_{wq}$	$L = 354 \text{ ft}$
4-3. If L is too long for the site, proceed to Step 5 to adjust the swale layout If L is greater than 100 ft and will fit within the constraints of the site, skip to Step 6 If L is less than 100 ft, increase the length to a minimum of 100 ft, leaving the bottom width unchanged, and skip to Step 6	Not Applicable

Site constraints only allow a swale length of 300 feet. Therefore proceed to Step 5 to adjust the swale length.

Step 5: Adjust Swale Layout to Fit Within Site Constraints

To adjust swale length to 300 feet, the bottom width needs to be increased (up to a maximum of 16 ft if a divider is provided).

Step 5: Adjust swale layout to fit within site constraints	
5-1. Enter the bottom width calculated in Step 2 (ft), $b_i = b$	$b_i = 5.0 \text{ ft}$
5-2. Enter design flow depth (ft), y	$y = 0.33 \text{ ft}$
5-3. Enter the swale side slope ratio (H:V), Z	$Z = 3 \text{ ft:ft}$
5-4. Enter the additional top width above the side slope for the design water depth (ft), $b_{slope} = 2Zy$	$b_{slope} = 2 \text{ ft}$
5-5. Enter the initial length calculated in Step 4 (ft), $L_i = L$	$L_i = 354 \text{ ft}$
5-6. Calculate the top area at the design treatment depth (ft ²), $A_{top} = (b_i + b_{slope}) \times L_i$	$A_{top} = 2,480 \text{ ft}^2$

5-7. Choose a reduced swale length based on site constraints (ft), L_f	$L_f = 300 \text{ ft}$
5-8. Calculate the increased bottom width (ft), $b_f = (A_{top}/L_f) - b_{slope}$	$b_f = 6.3 \text{ ft}$
5-9. Recalculate the cross-sectional area of flow at design depth (ft ²), $A_{wq,f} = b_f y + Zy^2$	$A_{wq,f} = 2.4 \text{ ft}^2$
5-10. Recalculate design flow velocity (ft/s), $V_{wq} = SQDF / A_{wq}$ Revise design as necessary if design flow velocity exceeds 1 ft/s.	$V_{wq} = 0.49 \text{ ft/s}$
5-11. Recalculate the hydraulic residence time (min), $t_{hr} = L_f / (60V_{wq})$ Ensure that t_{hr} is greater or equal to 10 minutes.	$t_{hr} = 10.2 \text{ min}$
5-12. When V_{wq} and t_{hr} are recalculated to meet requirements, proceed to Step 6.	

Since the new length and width yields V_{wq} and t_{hr} which meet requirements, continue to Step 6.

Step 6: Provide Conveyance Capacity for Flows Higher than SQDF

The swale will be offline such that all flows greater than SQDF will be bypassed.

E.7 VEG-4 Filter Strip

Sizing Methodology

The flow capacity of a vegetated filter strips (filter strips) is a function of the longitudinal slope (parallel to flow), the resistance to flow (e.g., Manning's roughness), and the width and length of the filter strip. The slope shall be small enough to ensure that the depth of water will not exceed 1 inch over the filter strip. Similarly, the flow velocity shall be less than 1 ft/sec. Procedures for sizing filter strips are summarized below. A filter strip sizing example is also provided.

Step 1: Calculate the design flow rate

The design flow is calculated based on the stormwater quality design flow rate, SQDF, as described in [Section E.1](#).

Step 2: Calculate the minimum width

Determine the minimum width (i.e. perpendicular to flow) allowable for the filter strip and design for that width or larger.

$$W_{min} = (SQDF) / (q_{a,min}) \quad \text{(Equation E-35)}$$

Where

- W_{min} = minimum width of filter strip
- $SQDF$ = stormwater quality design flow (cfs)
- $q_{a,min}$ = minimum linear unit application rate, 0.005 cfs/ft

Step 3: Calculate the design flow depth

The design flow depth (d_f) is calculated based on the width and the slope (parallel to the flow path) using a modified Manning's equation as follows:

$$d_f = 12 * [SQDF * n_{wq} / 1.49W_{trib} s^{0.5}]^{0.6} \quad \text{(Equation E-36)}$$

Where:

- d_f = design flow depth (inches)
- $SQDF$ = stormwater quality design flow (cfs)
- W_{trib} = width (perpendicular to flow = width of impervious surface contributing area (ft))
- s = slope (ft/ft) of strip parallel to flow, average over the whole width

n_{wq} = Manning's roughness coefficient (0.25-0.30)

If d_f is greater than 1 inch (0.083 ft), then a shallower slope is required, or a filter strip cannot be used.

Step 4: Calculate the design velocity

The design flow velocity is based on the design flow, design flow depth, and width of the strip:

$$V_{wq} = SQDF / (d_f W_{trib}) \quad \text{(Equation E-37)}$$

Where:

$d_{f,ft}$ = design flow depth (ft) ($d_f/12$)

$SQDF$ = stormwater quality design flow (cfs)

W_{trib} = width (perpendicular to flow = width of impervious surface contributing area (ft))

Step 5: Calculate the desired length of the filter strip

Determine the required length (L) to achieve a desired minimum residence time of 7 minutes using:

$$L = 60t_{hr}V_{wq} \quad \text{(Equation E-38)}$$

Where:

L = minimum allowable strip length (ft)

t_{hr} = hydraulic residence time (s)

V_{wq} = design flow velocity (fps)

Sizing Worksheet

Step 1: Calculate the design flow	
1-1. Enter Project area (acres), $A_{project}$	$A_{design} =$ acres
1-2. Enter impervious fraction, Imp (e.g. 60% = 0.60)	$Imp =$
1-3. Determine pervious runoff coefficient using Table E-1, C_p	$C_p =$
1-4. Calculate runoff coefficient, $C = 0.95*imp + C_p (1-imp)$	$C =$
1-5. Enter design rainfall intensity (in/hr), i	$i =$ in/hr
1-6. Calculate water quality design flow (cfs), $SQDF = CiA$	$SQDF =$ cfs
Step 2: Calculate the minimum width	
2-1. Enter the stormwater quality design flow (cfs), $SQDF$	$SQDF =$ cfs
2-2. Enter the minimum linear unit application rate (0.005 cfs/ft), $q_{a,min}$	$q_{a,min} =$ cfs/ft
2-3. Calculate the minimum width of filter strip (ft), W_{min}	$W_{min} =$ ft
Step 3: Calculate the design flow depth	
3-1. Enter filter strip longitudinal slope, s (ft/ft)	$s =$ ft/ft
3-2. Enter Manning roughness coefficient (0.25-0.30), n_{wq}	$n_{wq} =$
3-3. Enter width of impervious surface contributing area (perpendicular to flow), W (ft)	$W =$ ft

Step 3: Calculate the design flow depth	
3-4. Calculate average depth of water using Manning equation (inches), $d_f = 12 * [SQDF * n_{wq} / 1.49 W_{trib} s^{0.5}]^{0.6}$	$d_f =$ inches
3-5. If $d_f > 1$ " (0.083 ft), go back step 3-1 and decrease the slope	
3-6. If the slope cannot be changed due to construction constraints, go to step 3-3 and increase the width perpendicular to flow.	
Step 4: Calculate the design velocity	
4-1. Enter depth of water (ft), $d_{f,ft} = d_f / 12$	$d_{f,ft} =$ ft
4-2. Enter width of strip (ft), W	$W =$ ft
4-3. Calculate design flow velocity (ft/s), $V_{wq} = SQDF / (d_{f,ft} W)$	$V_{wq} =$ ft/s
4-4. If the $V_{wq} > 1$ ft/s, go back to step 3-1 and decrease the slope.	
Step 5: Calculate the length of the filter strip	
5-1. Enter desired residence time (minimum 7 minutes), t	$t =$ min
5-2. Enter design flow velocity (ft/s), V_{wq}	$V_{wq} =$ ft/s
5-3. Calculate length of the filter strip (ft), $L = 60tV_{wq}$	$L =$ ft
5-4. If $L < 4$ ft, go to step 3-1 and increase the slope	

Design Example

Step 1: Determine water quality design Flow

For this design example, a 10-acre site with Type 4 soil and 60% total imperviousness is considered. Flow-based sizing Method 1 is used, as described in [Section E.1](#).

Step 1: Calculate the design flow	
1-1. Enter Project area (acres), $A_{project}$	$A_{design} = 10$ acres
1-2. Enter impervious fraction, Imp (e.g. 60% = 0.60)	$Imp = 0.60$
1-3. Determine pervious runoff coefficient using Table E-1, C_p	$C_p = 0.05$
1-4. Calculate runoff coefficient, $C = 0.95 * imp + C_p (1 - imp)$	$C = 0.59$
1-5. Enter design rainfall intensity (in/hr), i	$i = 0.2$ in/hr
1-6. Calculate water quality design flow (cfs), $SQDF = CiA$	$SQDF = 1.18$ cfs

Step 2: Calculate the minimum width of filter strip

Determine the minimum width (i.e. perpendicular to flow) allowable for the filter strip and design for that width or larger.

Step 2: Calculate the minimum width	
2-1. Enter the stormwater quality design flow (cfs), $SQDF$	$SQDF = 1.18$ cfs
2-2. Enter the minimum linear unit application rate (0.005 cfs/ft), $q_{a,min}$	$q_{a,min} = 0.005$ cfs/ft
2-3. Calculate the minimum width of filter strip (ft), $W_{min} = SQDF / q_{a,min}$	$W_{min} = 240$ ft

Step 3: Calculate the Design Flow Depth

A slope of 3% was assumed for the filter strip (2-4% recommended). The design water depth should not exceed 1 inch. For this design example a manning's coefficient of 0.27 was used.

Step 3: Calculate the design flow depth	
3-1. Enter filter strip longitudinal slope, s (ft/ft)	$s = 0.03$ ft/ft
3-2. Enter Manning roughness coefficient (0.25-0.30), n_{wq}	$n_{wq} = 0.27$
3-3. Enter width of strip (=impervious surface contributing area perpendicular to flow), at least W_{min} (ft), W	$W = 240$ ft
3-4. Calculate average depth of water using Manning equation (inches), $d_f = 12 * [SQDF * n_{wq} / 1.49 W s^{0.5}]^{0.6}$	$d_f = 0.51$ in
3-5. If $d_f > 1$ " (0.083 ft), go back step 3-1 and decrease the slope	
3-6. If the slope cannot be changed due to construction constraints, go to step 3-3 and increase the width perpendicular to flow.	

Step 4: Calculate the Design Velocity

The designed flow velocity should not exceed 1 foot/second across the filter strip.

Step 4: Calculate the design velocity	
4-1. Enter depth of water (ft), $d_{f,ft} = d_f / 12$	$d_f = 0.043$ ft
4-2. Enter width of strip (ft), W	$W = 240$ ft
4-3. Calculate design flow velocity (ft/s), $V_{wq} = SQDF / (d_{f,ft} W)$	$V_{wq} = 0.11$ ft/s
4-4. If the $V_{wq} > 1$ ft/s, go back to step 3-1 and decrease the slope.	

Step 5: Calculate the Length of the Filter Strip

The filter strip should be at least 4 feet long (in the direction of flow) and accommodate a minimum residence time of 7 minutes to provide adequate water quality treatment.

Step 5: Calculate the length of the filter strip	
5-1. Enter desired residence time (minimum 10 minutes), t	$t = 10 \text{ min}$
5-2. Enter design flow velocity (ft/s), V_{wq}	$V_{wq} = 0.11 \text{ ft/s}$
5-3. Calculate length of the filter strip (ft), $L = 60tV_{wq}$	$L = 66 \text{ ft}$
5-4. If $L < 4 \text{ ft}$, go to step 3-1 and increase the slope	

E.8 TCM-1 Dry Extended Detention Basin

Sizing Methodology

Dry extended detention (ED) basins are basins designed such that the stormwater quality design volume, SQDV, is detained for 36 to 48 hours. This allows sediment particles and associated pollutants to settle and be removed from stormwater. Procedures for sizing extended detention basins are summarized below. A sizing example is also provided.

Step 1: Calculate the design volume

Dry extended detention facilities shall be sized to capture and treat the water quality design volume (see Section E.1).

Step 2: Calculate the volume of the active basin

The total basin volume shall be increased an additional 20% of the stormwater quality design volume to account for sediment accumulation, at a minimum. If the basin is designed only for water quality treatment then the basin volume would be 120% of the stormwater quality design volume, SQDV. Freeboard is in addition to the total basin volume. Calculate the volume of the active basin, V_a :

$$V_a = 1.20 * \text{SQDV} \quad (\text{Equation E-39})$$

Step 3: Determine detention basin location and preliminary geometry based on site constraints

Based on site constraints, determine the basin geometry and the storage available by developing an elevation-storage relationship for the basin. The cross-sectional geometry across the width of the basin shall be approximately trapezoidal with a maximum side slope of 4:1 (H:V) on interior slopes and 3:1 (H:V) on exterior slopes unless specifically permitted by Ventura County (see Side Slopes below). Shallower side slopes are necessary if the basin is designed to have recreational uses during dry weather conditions.

1) Calculate the width of the basin footprint, W_{tot} , as follows:

$$W_{tot} = \frac{A_{tot}}{L_{tot}} \quad (\text{Equation E-40})$$

Where:

A_{tot} = total surface area of the basin footprint (ft²)

L_{tot} = total length of the basin footprint (ft)

- 2) Calculate the length of the active volume surface area including the internal berm but excluding the freeboard, L_{av-tot} :

$$L_{av-tot} = L_{tot} - 2Zd_{fb} \quad (\text{Equation E-41})$$

Where:

Z = interior side slope as length per unit height

d_{fb} = freeboard depth

- 3) Calculate the width of the active volume surface area including the internal berm but excluding freeboard, W_{av-tot} :

$$W_{av-tot} = W_{tot} - 2Zd_{fb} \quad (\text{Equation E-42})$$

- 4) Calculate the total active volume surface area including the internal berm and excluding freeboard, A_{av-tot} :

$$A_{av-tot} = L_{av-tot} \times W_{av-tot} \quad (\text{Equation E-43})$$

- 5) Calculate the area of the berm, A_{berm} :

$$A_{berm} = W_{berm} \times L_{berm} \quad (\text{Equation E-44})$$

Where:

W_{berm} = width of the internal berm

L_{berm} = length of the internal berm

- 6) Calculate the surface area excluding the internal berm and freeboard, A_{av} :

$$A_{av} = A_{av-tot} - A_{berm} \quad (\text{Equation E-45})$$

Step 4: Determine Dimensions of Forebay

5-15% of the basin active volume, V_a , is required to be within the active volume of the forebay.

- 1) Calculate the active volume of forebay, V_1 :

$$V_1 = \frac{V_a \times \%V_1}{100} \quad (\text{Equation E-46})$$

Where:

$\%V_1$ = percent of V_a in forebay (%)

V_a = active volume (ft³)

- 2) Calculate the surface area for the active volume of forebay, A_1 :

$$A_1 = \frac{V_1}{d_1} \quad (\text{Equation E-47})$$

Where:

d_1 = average depth for the active volume of forebay (ft)

- 3) Calculate the length of forebay, L_1 :

$$L_1 = \frac{A_1}{W_1} \quad (\text{Equation E-48})$$

Where:

W_1 = width of forebay (ft)

Step 5: Determine Dimensions of Cell 2

Cell 2 will consist of the remainder of the basin's active volume.

- 1) Calculate the active volume of Cell 2, V_2 :

$$V_2 = V_a - V_1 \quad (\text{Equation E-49})$$

Where:

V_a = total basin active volume (ft³)

V_1 = volume of forebay (ft³)

- 2) Calculate the surface area, A_2 , for the active volume of Cell 2:

$$A_2 = A_{av} - A_1 \quad (\text{Equation E-50})$$

Where:

A_{av} = basin surface area excluding berm and freeboard (ft²)

A_1 = surface area of forebay (ft²)

- 3) Calculate the average depth, d_2 , for the active volume of Cell 2:

$$d_2 = \frac{V_2}{A_2} \quad (\text{Equation E-51})$$

- 4) Calculate the length of Cell 2, L_2 :

$$L_2 = \frac{A_2}{W_2} \quad \text{(Equation E-52)}$$

Where:

W_2 = width of Cell 2 (ft)

- 5) Verify that the length-to-width ratio of Cell 2 at half of d_2 is at least 1.5:1 with \geq 2:1 preferred. If the length-to width ratio is less than 1.5:1, modify input parameters until a ratio of at least 1.5:1 is achieved. If the input parameters cannot be modified as a result of site constraints, another site for the basin should be chosen. Calculate the length-to width, LW_{mid2} , ratio of Cell 2 at half of d_2 follows:

$$LW_{mid2} = \frac{L_{mid2}}{W_{mid2}} \quad \text{(Equation E-53)}$$

Where:

$$W_{mid2} = W_2 - Zd_2 \text{ and} \quad \text{(Equation E-54)}$$

$$L_{mid2} = L_2 - Zd_2 \quad \text{(Equation E-55)}$$

W_{mid2} = width of Cell 2 at half of d_2 (ft)

L_{mid2} = length of Cell 2 at half of d_2 (ft)

Z = interior side slope as length per unit height (H:V)

Step 6: Ensure Design Requirements and Site Constraints are achieved

Check design requirements and site constraints. Modify design geometry until requirements are met. If the chosen site for the basin is inadequate to meet the design requirements, choose a new location or alternative treatment BMP.

Step 7: Size Outlet Structure

The total drawdown time for the basin should be 36-48 hours. The outlet structure shall be designed to release the bottom 50% of the detention volume (half-full to empty) over 24-32 hours, and the top half (full to half-full) in 12-16 hours. A primary overflow should be sized to pass the peak flow rate from the developed capital design storm. See Section 6 for outlet structure sizing methodologies.

Step 8: Determine Emergency Spillway Requirements

For online basins, an emergency overflow spillway should be sized to pass flows greater than the design peak runoff discharge rate for the 100-yr, 24-hr storm in order to prevent overtopping of the walls or berms in the event that a blockage of the riser occurs. For offline basins, an emergency spillway or riser should be sized to pass

the 100-yr, 24-hr post-development peak storm water runoff discharge rate directly to the downstream conveyance system or another acceptable discharge point. For sites where the emergency spillway discharges to a steep slope, an emergency overflow riser, in addition to the spillway should be provided.

Sizing Worksheet

Step 1: Determine water quality design volume		
1-1. Enter Project area (acres), $A_{project}$	$A =$	acres
1-2. Enter the maximum allowable percent of the Project area that may be effective impervious area (refer to permit), ranges from 5-30%, $\%_{allowable}$	$\%_{allowable} =$	%
1-3. Determine the maximum allowed effective impervious area (ac), $EIA_{allowable} = (A_{project}) * (\%_{allowable})$	$EIA_{allowable} =$	acres
1-4. Enter Project impervious fraction, Imp (e.g. 60% = 0.60)	$Imp =$	
1-5. Determine the Project Total Impervious area (acres), $TIA = A_{project} * Imp$	$TIA =$	acres
1-6. Determine the total area from which runoff must be retained (acres), $A_{retain} = TIA - EIA_{allowable}$	$A_{retain} =$	acres
1-7. Determine pervious runoff coefficient using <u>Table E-1</u> , C_p	$C_p =$	
1-8. Calculate runoff coefficient, $C = 0.95 * imp + C_p (1 - imp)$	$C =$	
1-9. Enter design rainfall depth of the storm (in), P_i	$P_i =$	in
1-10. Calculate rainfall depth (ft), $P = P_i / 12$	$P =$	ft
1-11. Calculate water quality design volume (ft ³), $SQDV = 43560 * C * P * A_{retain}$	$SQDV =$	ft ³
Step 2: Calculate the volume of the active basin		
2-1. Calculate basin active volume (includes water quality design volume + sediment storage volume) (ft ³), $V_a = 1.20 * SQDV$	$V_a =$	ft ³

Step 3: Determine Detention Basin Location and Preliminary Geometry Based on Site Constraints		
3-1. Based on site constraints, determine the basin geometry and the storage available by developing an elevation-storage relationship for the basin. For this simple example, assume a trapezoidal geometry for cell 1 (forebay) and cell 2.		
3-2. Enter the total surface area of the basin footprint based on site constraints (ft ²), A_{tot}	$A_{tot} =$	ft ²
3-3. Enter the length of the basin footprint based on site constraints (ft), L_{tot}	$L_{tot} =$	ft
3-4. Calculate the width of the basin footprint (L:W = 1.5:1 min) (ft), $W_{tot} = A_{tot} / L_{tot}$	$W_{tot} =$	ft
3-5. Enter interior side slope as length per unit height (H:V, min = 3), Z	$Z =$	
3-6. Enter desired freeboard depth (ft), d_{fb} (min: 2 ft on-line; 1 ft offline)	$d_{fb} =$	ft
3-7. Calculate the length of the active volume surface area including the internal berm but excluding freeboard, $L_{av-tot} = L_{tot} - 2Zd_{fb}$	$L_{av-tot} =$	ft
3-8. Calculate the width of the active volume surface area including the internal berm but excluding freeboard, $W_{av-tot} = W_{tot} - 2Zd_{fb}$	$W_{av-tot} =$	ft
3-9. Calculate the total active volume surface area including the internal berm and excluding freeboard, $A_{av-tot} = L_{av-tot} \times W_{av-tot}$	$A_{av-tot} =$	ft ²
3-10. Enter the width of the internal berm (6 ft min), W_{berm}	$W_{berm} =$	ft
3-11. Enter the length of the internal berm (ft), $L_{berm} = W_{av-tot}$	$L_{berm} =$	ft
3-12. Calculate the area of the berm (ft ²), $A_{berm} = W_{berm} \times L_{berm}$	$A_{berm} =$	ft ²
3-13. Calculate the surface area excluding the internal berm and freeboard (ft ²), $A_{av} = A_{av-tot} - A_{berm}$	$A_{av} =$	ft ²

Step 4: Determine Dimensions of forebay	
4-1. Enter the percent of V_a in forebay (5-15% required), $\%V_1$	$\%V_1 =$ %
4-2. Calculate the active volume of forebay, $V_1 = (V_a \cdot \%V_1)/100$	$V_1 =$ ft ³
4-3. Enter a desired average depth for the active volume of forebay, d_1	$d_1 =$ ft
4-4. Calculate the surface area for the active volume of forebay, $A_1 = V_1 / d_1$	$A_1 =$ ft ²
4-5. Enter the width of forebay, $W_1 = W_{av-tot} = L_{berm}$	$W_1 =$ ft
4-6. Calculate the length of forebay (<u>Note</u> : inlet and outlet should be configured to maximize the residence time), $L_1 = A_1 / W_1$	$L_1 =$ ft
Step 5: Determine Dimensions of Cell 2	
5-1. Calculate the active volume of Cell 2, $V_2 = V_a - V_1$	$V_2 =$ ft ³
5-2. Calculate the surface area of the active volume of Cell 2, $A_2 = A_{av} - A_1$	$A_2 =$ ft ²
5-3. Calculate the average depth for the active volume of Cell 2, $d_2 = V_2 / A_2$	$d_2 =$ ft
5-4. Enter the width of Cell 2, $W_2 = W_1 = W_{av-tot} = L_{berm}$	$W_2 =$ ft
5-5. Calculate the length of Cell 2, $L_2 = A_2 / W_2$	$L_2 =$ ft
5-6. Calculate the width of Cell 2 at half of d_2 , $W_{mid2} = W_2 - Zd_2$	$W_{mid2} =$ ft
5-7. Calculate the length of Cell 2 at half of d_2 , $L_{mid2} = L_2 - Zd_2$	$L_{mid2} =$ ft

<p>5-8. Verify that the length-to-width ratio of Cell 2 at half of d_2 is at least 1.5:1 with $\geq 2:1$ preferred. If the length-to-width ratio is less than 1.5:1, modify input parameters until a ratio of at least 1.5:1 is achieved. If the input parameters cannot be modified as a result of site constraints, another site for the basin should be chosen, $LW_{mid2} = L_{mid2} / W_{mid2}$</p>	<p>$LW_{mid2} =$</p>
<p>Step 6: Ensure Design Requirements and Site Constraints are Achieved</p>	
<p>6-1. Check design requirements and site constraints. Modify design geometry until requirements are met. If the chosen site for the basin is inadequate to meet the design requirements, choose a new location or alternative treatment BMP.</p>	
<p>Step 7: Size Outlet Structure</p>	
<p>7-1. The total drawdown time for the basin should be 36-48 hours. The outlet structure shall be designed to release the bottom 50% of the detention volume (half-full to empty) over 24-32 hours, and the top half (full to half-full) in 12-16 hours. A primary overflow should be sized to pass the peak flow rate from the developed capital design storm. See Section 6 for outlet structure sizing methodologies.</p>	
<p>Step 8: Determine Emergency Spillway Requirements</p>	
<p>8-1. For online basins, an emergency overflow spillway should be sized to pass flows greater than the design peak runoff discharge rate for the 100-yr, 24-hr storm in order to prevent overtopping of the walls or berms in the event that a blockage of the riser occurs. For offline basins, an emergency spillway or riser should be sized to pass the 100-yr, 24-hr post-development peak storm water runoff discharge rate directly to the downstream conveyance system or another acceptable discharge point. For sites where the emergency spillway discharges to a steep slope, an emergency overflow riser, in addition to the spillway should be provided.</p>	

Design Example

Step 1: Determine water quality design volume

For this design example, a 10-acre residential development with a 60% total impervious area is considered. The 85th percentile storm event for the project location is 0.75 inches.

Step 1: Determine water quality design volume	
1-1. Enter Project area (acres), $A_{project}$	$A = 10$ acres
1-2. Enter the maximum allowable percent of the Project area that may be effective impervious area (refer to permit), ranges from 5-30%, $\%_{allowable}$	$\%_{allowable} = 5$
1-3. Determine the maximum allowed effective impervious area (ac), $EIA_{allowable} = (A_{project}) * (\%_{allowable})$	$EIA_{allowable} = 0.5$ acres
1-4. Enter Project impervious fraction, Imp (e.g. 60% = 0.60)	$Imp = 0.6$
1-5. Determine the Project Total Impervious area (acres), $TIA = A_{project} * Imp$	$TIA = 6$ acres
1-6. Determine the total area from which runoff must be retained (acres), $A_{retain} = TIA - EIA_{allowable}$	$A_{retain} = 5.5$ acres
1-7. Determine pervious runoff coefficient using Table E-1 , C_p	$C_p = 0.05$
1-8. Calculate runoff coefficient, $C = 0.95 * imp + C_p (1 - imp)$	$C = 0.59$
1-9. Enter design rainfall depth of the storm (in), P_i	$P_i = 0.75$ in
1-10. Calculate rainfall depth (ft), $P = P_i / 12$	$P = 0.06$ ft
1-11. Calculate water quality design volume (ft ³), $SQDV = 43560 * C * P * A_{retain}$	$SQDV = 8,500$ ft ³

Step 2: Calculate Volume of the Active Basin and the Forebay Basin

Step 2: Calculate the design volume of the active basin	
2-1. Calculate basin active design volume (includes water quality design volume + sediment storage volume), $V_a = 1.20 * SQDV$	$V_a = 10,000 \text{ ft}^3$

Step 3: Determine Detention Basin Location and Preliminary Geometry Based on Site Constraints

The detention basin in this example has an internal berm separating the forebay (Cell 1) and the main basin (Cell 2). The internal berm elevation is 2 ft below the elevation of the SUSMP volume within the entire basin. The berm length is equal to the width of the basin when filled to the active design volume.

Step 3: Determine Detention Basin Location and Preliminary Geometry Based on Site Constraints	
3-1. Based on site constraints, determine the basin geometry and the storage available by developing an elevation-storage relationship for the basin. For this simple example, assume a trapezoidal geometry for cell 1 (forebay) and cell 2.	
3-2. Enter the total surface area of the basin footprint based on site constraints, A_{tot}	$A_{tot} = 8,000 \text{ ft}^2$
3-3. Enter the length of the basin footprint based on site constraints, L_{tot} (L:W = 1.5:1 min)	$L_{tot} = 200 \text{ ft}$
3-4. Calculate the width of the basin footprint, $W_{tot} = A_{tot} / L_{tot}$	$W_{tot} = 40 \text{ ft}$
3-5. Enter interior side slope as length per unit height (min = 3), Z	$Z = 3$
3-6. Enter desired freeboard depth, d_{fb} (min: 2 ft on-line; 1 ft offline)	$d_{fb} = 2 \text{ ft}$
3-7. Calculate the length of the active volume surface area including the internal berm but excluding freeboard, $L_{av-tot} = L_{tot} - 2Zd_{fb}$	$L_{av-tot} = 188 \text{ ft}$

Step 3: Determine Detention Basin Location and Preliminary Geometry Based on Site Constraints	
3-8. Calculate the width of the active volume surface area including the internal berm but excluding freeboard, $W_{av-tot} = W_{tot} - 2Zd_{fb}$	$W_{av-tot} = 28 \text{ ft}$
3-9. Calculate the total active volume surface area including the internal berm and excluding freeboard, $A_{av-tot} = L_{av-tot} \cdot W_{av-tot}$	$A_{av-tot} = 5,300 \text{ ft}^2$
3-10. Enter the width of the internal berm (6 ft min), W_{berm}	$W_{berm} = 6 \text{ ft}$
3-11. Enter the length of the internal berm, $L_{berm} = W_{av-tot}$	$L_{berm} = 28 \text{ ft}$
3-12. Calculate the area of the berm, $A_{berm} = W_{berm} \cdot L_{berm}$	$A_{berm} = 170 \text{ ft}^2$
3-13. Calculate the surface area excluding the internal berm and freeboard, $A_{av} = A_{av-tot} - A_{berm}$	$A_{av} = 5,130 \text{ ft}^2$

Step 4: Calculate Dimensions of Cell 1

Calculate the dimensions of the forebay (Cell 1) based on the active design volume for Cell 1 (25% of V_a) and a desired average depth, d_1 . The width of the forebay, W_1 , is equivalent to the length of the berm, L_{berm} , and the width of Cell 2, W_2 .

Step 4: Determine Dimensions of forebay	
4-1. Enter the percent of V_a in forebay (5-15% required), $\%V_1$	$\%V_1 = 25 \%$
4-2. Calculate the active volume of forebay (including sediment storage), $V_1 = (V_a \cdot \%V_1)/100$	$V_1 = 2,500 \text{ ft}^3$
4-3. Enter a desired average depth for the active volume of forebay, d_1	$d_1 = 5 \text{ ft}$
4-4. Calculate the surface area for the active volume of forebay, $A_1 = V_1 / d_1$	$A_1 = 500 \text{ ft}^2$

4-5. Enter the width of forebay, $W_1 = W_{wq-tot} = L_{berm}$	$W_1 =$ 28 ft
4-6. Calculate the length of forebay (<u>Note:</u> inlet and outlet should be configured to maximize the residence time), $L_1 = A_1 / W_1$	$L_1 =$ 18 ft

Step 5: Calculate the Dimensions of Cell 2

Calculate the dimensions of the main basin (Cell 2) based on the active design volume for Cell 2 and a desired average depth, d_2 . A calculation of the length, L_{mid2} , and width, W_{mid2} , at half basin depth, d_2 , is conducted in order to verify that the length-to-width ratio at half d_2 is greater than 1.5:1.

Step 5: Calculate the dimensions of Cell 2	
5-1. Calculate the active volume of Cell 2, $V_2 = V_a - V_1$	$V_2 =$ 7,500 ft ³
5-2. Calculate the surface area of the active volume of Cell 2, $A_2 = A_{av} - A_1$	$A_2 =$ 4,630 ft ²
5-3. Calculate the average depth of the active volume of Cell 2, $d_2 = V_2 / A_2$	$d_2 =$ 1.6 ft
5-4. Enter the width of Cell 2, $W_2 = W_1 = W_{av-tot} = L_{berm}$	$W_2 =$ 28 ft
5-5. Calculate the length of Cell 2, $L_2 = A_2 / W_2$	$L_2 =$ 166 ft
5-6. Calculate the width of Cell 2 at half of d_2 , $W_{mid2} = W_2 - Zd_2$	$W_{mid2} =$ 23 ft
5-7. Calculate the length of Cell 2 at half of d_2 , $L_{mid2} = L_2 - Zd_2$	$L_{mid2} =$ 161 ft
5-8. Verify that the length-to-width ratio of Cell 2 at half of d_2 is at least 1.5:1 with $\geq 2:1$ preferred. If the length-to-width ratio is less than 1.5:1, modify input parameters until a ratio of at least 1.5:1 is achieved. If the input parameters cannot be modified as a result of site constraints, another site for the basin should be chosen, $LW_{mid2} = L_{mid2} / W_{mid2}$	$LW_{mid2} =$ 7

Step 6: Ensure Design Requirements and Site Constraints are Achieved

Check design requirements and site constraints. Modify design geometry until requirements are met. If the chosen site for the basin is inadequate to meet the design requirements, choose a new location or an alternative treatment BMP.

Step 7: Size Outlet Structure

The total drawdown time for the basin should be 36-48 hours. The outlet structure shall be designed to release the bottom 50% of the detention volume (half-full to empty) over 24-32 hours, and the top half (full to half-full) in 12-16 hours. A primary overflow should be sized to pass the peak flow rate from the developed capital design storm. See Section 6 for outlet structure sizing methodologies.

Step 8: Determine Emergency Spillway Requirements

For online basins, an emergency overflow spillway should be sized to pass flows greater than the design peak runoff discharge rate for the 100-yr, 24-hr storm in order to prevent overtopping of the walls or berms in the event that a blockage of the riser occurs. For offline basins, an emergency spillway or riser should be sized to pass the 100-yr, 24-hr post-development peak storm water runoff discharge rate directly to the downstream conveyance system or another acceptable discharge point. For sites where the emergency spillway discharges to a steep slope, an emergency overflow riser, in addition to the spillway should be provided.

E.9 TCM-2 Wet Detention Basin

Sizing Methodology

Wet Detention basins may be designed with or without extended detention above the permanent pool. The extended detention portion of the wet detention basin above the permanent pool, if provided, functions like a dry extended detention (ED) basin (see [VEG-5: Dry Extended Detention Basin](#)). If there is no extended detention provided, wet detention basins shall be sized to provide a minimum wet pool volume equal to the stormwater quality design volume plus an additional 5% for sediment accumulation. If extended detention is provided above the permanent pool, the sizing is dependent of the functionality of the basin; the basin may function as water quality treatment only or water quality plus peak flow attenuation.

If and the basin is designed for water quality treatment only, then the permanent pool volume shall be a minimum of 10 percent of the stormwater quality design volume and the surcharge volume (above the permanent pool) shall make up the remaining 90 percent. If extended detention is provided above the permanent pool and the basin is designed for water quality treatment and peak flow attenuation, then the permanent pool volume shall be equal to the water quality treatment volume, and the surcharge volume shall be sized to attenuate peak flows in order to meet the peak runoff discharge requirements. The extended detention portion of the wet detention basin above the permanent pool, if provided, functions like a dry extended detention (ED) basin (see [VEG-5: Dry Extended Detention Basin](#)).

Step 1: Calculate the design volume

Wet detention basins shall be sized with a permanent pool volume equal to the SQDV volume (see [Section 2](#) and Appendix E).

Step 2: Determine the active design volume for the wet detention basin without extended detention

The active volume of the wet detention basin, V_a , shall be equal to the SQFV plus an additional 5% for sediment accumulation.

$$V_a = 1.05 \times SQDV \quad \text{(Equation E-56)}$$

Step 3: Determine pond location and preliminary geometry based on site constraints

Based on site constraints, determine the pond geometry and the storage available by developing an elevation-storage relationship for the pond. Note that a more natural geometry may be used and is in many cases recommended; the preliminary basin geometry calculations should be used for sizing purposes only.

- 1) Calculate the width of the pond footprint, W_{tot} , as follows:

$$W_{tot} = \frac{A_{tot}}{L_{tot}} \quad \text{(Equation E-57)}$$

Where:

A_{tot} = total surface area of the pond footprint (ft²)

L_{tot} = total length of the pond footprint (ft)

- 7) Calculate the length of the active volume surface area including the internal berm but excluding the freeboard, L_{av-tot} :

$$L_{av-tot} = L_{tot} - 2Zd_{fb} \quad \text{(Equation E-58)}$$

Where:

Z = interior side slope as length per unit height

d_{fb} = freeboard depth

- 8) Calculate the width of the active volume surface area including the internal berm but excluding freeboard, W_{av-tot} :

$$W_{av-tot} = W_{tot} - 2Zd_{fb} \quad \text{(Equation E-59)}$$

- 9) Calculate the total active volume surface area including the internal berm and excluding freeboard, A_{av-tot} :

$$A_{av-tot} = L_{av-tot} \times W_{av-tot} \quad \text{(Equation E-60)}$$

- 10) Calculate the area of the berm, A_{berm} :

$$A_{berm} = W_{berm} \times L_{berm} \quad \text{(Equation E-61)}$$

Where:

W_{berm} = width of the internal berm

L_{berm} = length of the internal berm

- 11) Calculate the active volume surface area excluding the internal berm and freeboard, A_{wq} :

$$A_{wq} = A_{wq-tot} - A_{berm} \quad \text{(Equation E-62)}$$

Step 4: Determine Dimensions of Forebay

The wet detention basin shall be divided into two cells separated by a berm or baffle. The forebay shall contain between 5 and 10 percent of the total volume. The berm or

baffle volume shall not count as part of the total volume. Calculate the active volume of forebay, V_1 :

$$V_1 = \frac{V_a \times \%V_1}{100} \quad (\text{Equation E-63})$$

Where:

$\%V_1$ = percent of SQDV in forebay (%)

- 1) Calculate the surface area for the active volume of forebay, A_1 :

$$A_1 = \frac{V_1}{d_1} \quad (\text{Equation E-64})$$

Where:

d_1 = average depth for the active volume of forebay (ft)

- 2) Calculate the length of forebay, L_1 . Note, inlet and outlet should be configured to maximize the residence time.

$$L_1 = \frac{A_1}{W_1} \quad (\text{Equation E-65})$$

Where:

W_1 = width of forebay (ft), $W_1 = W_{av-tot} = L_{berm}$

Step 5: Determine Dimensions of Cell 2

Cell 2 will consist of the remainder of the basin's active volume.

- 3) Calculate the active volume of Cell 2, V_2 :

$$V_2 = V_a - V_1 \quad (\text{Equation E-66})$$

- 4) The minimum wetpool surface area includes 0.3 acres of wetpool per acre-foot of permanent wetpool volume. Calculate A_{min2} :

$$A_{min2} = (V_2 \times 0.3 \frac{\text{acres}}{\text{acre-foot}}) \quad (\text{Equation E-67})$$

- 5) Calculate the actual wetpool surface area, A_2 :

$$A_2 = A_{av} - A_1 \quad (\text{Equation E-68})$$

Verify that A_2 is greater than A_{min2} . If A_2 is less than A_{min2} , then modify input parameters to increase A_2 until it is greater than A_{min2} . If site constraints limit this criterion, then another site for the pond should be chosen.

- 6) Calculate the top length of Cell 2, L_2 :

$$L_2 = \frac{A_2}{W_2} \quad \text{(Equation E-69)}$$

Where:

W_2 = width of Cell 2 (ft), $W_2 = W_1 = W_{wq-tot} = L_{berm}$

- 7) Verify that the length-to-width ratio of Cell 2 is at least 1.5:1 with $\geq 2:1$ preferred. If the length-to-width ratio is less than 1.5:1, modify input parameters until a ratio of at least 1.5:1 is achieved. If the input parameters cannot be modified as a result of site constraints, another site for the pond should be chosen.

$$LW_2 = \frac{L_2}{W_2} \quad \text{(Equation E-70)}$$

- 8) Calculate the emergent vegetation surface area, A_{ev} :

$$A_{ev} = \frac{A_2 \cdot \%A_{ev}}{100} \quad \text{(Equation E-71)}$$

Where:

$\%A_{ev}$ = percent of surface area that will be planted with emergent vegetation

- 9) Calculate the volume of the emergent vegetation shallow zone (1.5 – 3 ft), V_{ev} :

$$V_{ev} = A_{ev} \cdot d_{ev} \quad \text{(Equation E-72)}$$

Where:

d_{ev} = average depth of the emergent vegetation shallow zone (1.5 – 3 ft)

- 10) Calculate the length of the emergent vegetation shallow zone, L_{ev} :

$$L_{ev} = \frac{A_{ev}}{W_{ev}} \quad \text{(Equation E-73)}$$

Where:

W_{ev} = width of the emergent vegetation shallow zone (ft), $W_{ev} = W_2$

- 11) Calculate the volume of the deep zone, V_{deep} :

$$V_{deep} = V_2 - V_{ev} \quad \text{(Equation E-74)}$$

- 12) Calculate the surface area of the deep (>3 ft) zone, A_{deep} :

$$A_{deep} = A_2 - A_{ev} \quad (\text{Equation E-75})$$

13) Calculate the average depth of the deep zone (4-8 ft), d_{deep} :

$$d_{deep} = \frac{V_{deep}}{A_{deep}} \quad (\text{Equation E-76})$$

14) Calculate length of the deep zone, L_{deep} :

$$L_{deep} = \frac{A_{deep}}{W_{deep}} \quad (\text{Equation E-77})$$

Where:

W_{deep} = width of the deep zone (ft), $W_{deep} = W_2$

Step 6: Ensure design requirements and site constraints are achieved

Check design requirements and site constraints. Modify design geometry until requirements are met. If the chosen site for the basin is inadequate to meet the design requirements, choose a new location for the BMP.

Step 7: Size Outlet Structure

For extended detention wet detention basin, outlet structures shall be designed to provide 12 to 48 hour emptying time for the water quality volume above the permanent pool.

The basin outlet pipe shall be sized, at a minimum, to pass flows greater than the stormwater quality design peak flow for off-line basins or flows greater than the peak runoff discharge rate for the 100-year, 24-hr design storm for on-line basins.

Step 8: Determine Emergency Spillway Requirements

For online basins, an emergency overflow spillway should be sized to pass flows greater than the design peak runoff discharge rate for the 100-yr, 24-hr storm to prevent overtopping of the walls or berms in the event that a blockage of the riser occurs. For offline basins, an emergency spillway or riser should be sized to pass the water quality design storm. For sites where the emergency spillway discharges to a steep slope, an emergency overflow riser, in addition to the spillway should be provided.

Sizing Worksheet

Step 1: Determine water quality design volume		
1-1. Enter drainage area, A	A =	acres
1-2. Enter the maximum allowable percent of the Project area that may be effective impervious area (refer to permit), ranges from 5-30%, $\%_{allowable}$	$\%_{allowable} =$	%
1-3. Determine the maximum allowed effective impervious area, $EIA_{allowable} = (A_{project}) * (\%_{allowable})$	$EIA_{allowable} =$	acres
1-4. Enter Project impervious fraction, Imp (e.g. 60% = 0.60)	Imp =	
1-5. Determine the Project Total Impervious area, $TIA = A_{project} * Imp$	TIA =	acres
1-6. Determine the total area from which runoff must be retained, $A_{retain} = TIA - EIA_{allowable}$	$A_{retain} =$	acres
1-7. Determine pervious runoff coefficient using Table E-1, C_p	$C_p =$	
1-8. Calculate runoff coefficient, $C = 0.95 * imp + C_p (1 - imp)$	C =	
1-9. Enter design rainfall depth of the storm, P_i (in)	$P_i =$	in
1-10. Calculate rainfall depth, $P = P_i / 12$	P =	ft
1-11. Calculate water quality design volume, $SQDV = 43560 * P * A_{retain} * C$	SQDV =	ft ³
Step 2: Determine active design volume for the wet pond without extended detention		
2-1. Calculate the active design volume (without extended detention), $V_a = 1.05 * SQDV$	$V_a =$	ft ³

Step 3: Determine Pond Location and Preliminary Geometry Based on Site Constraints	
3-1. Based on site constraints, determine the pond geometry and the storage available by developing an elevation-storage relationship for the pond. For this simple example, assume a trapezoidal geometry for cell 1 (forebay) and cell 2.	
3-2. Enter the total surface area of the pond footprint based on site constraints, A_{tot}	$A_{tot} =$ ft ²
3-3. Enter the length of the pond footprint based on site constraints, L_{tot}	$L_{tot} =$ ft
3-4. Calculate the width of the pond footprint, $W_{tot} = A_{tot} / L_{tot}$	$W_{tot} =$ ft
3-5. Enter interior side slope as length per unit height (min = 3), Z	$Z =$
3-6. Enter desired freeboard depth, d_{fb} (1 ft min)	$d_{fb} =$ ft
3-7. Calculate the length of the water quality volume surface area including the internal berm but excluding freeboard, $L_{av-tot} = L_{tot} - 2Zd_{fb}$	$L_{av-tot} =$ ft
3-8. Calculate the width of the water quality volume surface area including the internal berm but excluding freeboard, $W_{av-tot} = W_{tot} - 2Zd_{fb}$	$W_{av-tot} =$ ft
3-9. Calculate the total water quality volume surface area including the internal berm and excluding freeboard, $A_{av-tot} = L_{av-tot} \cdot W_{av-tot}$	$A_{av-tot} =$ ft ²
3-10. Enter the width of the internal berm (6 ft min), W_{berm}	$W_{berm} =$ ft
3-11. Enter the length of the internal berm, $L_{berm} = W_{av-tot}$	$L_{berm} =$ ft
3-12. Calculate the area of the berm, $A_{berm} = W_{berm} \cdot L_{berm}$	$A_{berm} =$ ft ²

3-13. Calculate the water quality volume surface area excluding the internal berm and freeboard, $A_{av} = A_{av-tot} - A_{berm}$	$A_{av} =$ ft^2
Step 4: Determine Dimensions of forebay	
4-1. Enter the percent of V_a in forebay (5-10% required), $\%V_1$	$\%V_1 =$ $\%$
4-2. Calculate the active volume of forebay (includes sediment storage volume), $V_1 = (V_a \cdot \%V_1) / 100$	$V_1 =$ ft^3
4-3. Enter desired average depth of forebay (5-9 ft including sediment storage of 1 ft), d_1	$d_1 =$ ft
4-4. Calculate the surface area for the active volume of forebay, $A_1 = V_1 / d_1$	$A_1 =$ ft^2
4-5. Enter the width of forebay, $W_1 = W_{av-tot} = L_{berm}$	$W_1 =$ ft
4-6. Calculate the length of forebay (Note: inlet and outlet should be configured to maximize the residence time), $L_1 = A_1 / W_1$	$L_1 =$ ft
Step 5: Determine Dimensions of Cell 2	
5-1. Calculate the active volume of Cell 2, $V_2 = V_a - V_1$	$V_2 =$ ft^3
5-2. Determine minimum wetpool surface area, $A_{min2} = V_2 \cdot 0.3$	$A_{min2} =$ ft^2
5-3. Determine actual wetpool surface area, $A_2 = A_{av} - A_1$	$A_2 =$ ft^2
5-4. <ul style="list-style-type: none"> • If A_2 is greater than A_{min2} then move on to step 5-5. • If A_2 is less than A_{min2}, then modify input parameters to increase A_2 until it is greater than A_{min2}. If site constraints limit this criterion, then another site for the pond should be chosen. 	
5-5. Enter width of Cell 2, $W_2 = W_1 = W_{av-tot} = L_{berm}$	$W_2 =$ ft

5-6. Calculate top length of Cell 2, $L_2 = A_2 / W_2$	$L_2 =$ ft
5-7. Verify that the length-to-width ratio of Cell 2 is at least 1.5:1 with $\geq 2:1$ preferred. If the length-to-width ratio is less than 1.5:1, modify input parameters until a ratio of at least 1.5:1 is achieved. If the input parameters cannot be modified as a result of site constraints, another site for the pond should be chosen, $LW_2 = L_2 / W_2$	$LW_2 =$
5-8. Enter percent of surface area that will be planted with emergent vegetation (25-75%), $\%A_{ev}$	$\%A_{ev} =$ %
5-9. Calculate emergent vegetation surface area, $A_{ev} = (A_2 \cdot \%A_{ev}) / 100$	$A_{ev} =$ ft ²
5-10. Enter average depth of emergent vegetation shallow zone (1.5 – 3 ft), d_{ev}	$d_{ev} =$ ft
5-11. Calculate volume of emergent vegetation shallow zone (1.5 – 3 ft), $V_{ev} = A_{ev} \cdot d_{ev}$	$V_{ev} =$ ft ³
5-12. Enter width of emergent vegetation shallow zone, $W_{ev} = W_2$	$W_{ev} =$ ft
5-13. Calculate length of emergent vegetation shallow zone, $L_{ev} = A_{ev} / W_{ev}$	$L_{ev} =$ ft
5-14. Calculate volume of deep zone, $V_{deep} = V_2 - V_{ev}$	$V_{deep} =$ ft ³
5-15. Calculate surface area of deep (>3 ft) zone, $A_{deep} = A_2 - A_{ev}$	$A_{deep} =$ ft ²
5-16. Calculate average depth of deep zone (4 - 8 ft), $d_{deep} = V_{deep} / A_{deep}$	$d_{deep} =$ ft
5-17. Enter width of deep zone, $W_{deep} = W_2$	$W_{deep} =$ ft
5-18. Calculate length of deep zone, $L_{deep} = A_{deep} / W_{deep}$	$L_{deep} =$ ft

Step 6: Ensure Design Requirements and Site Constraints are Achieved

6-1. Check design requirements and site constraints. Modify design geometry until requirements are met. If the chosen site for the basin is inadequate to meet the design requirements, choose a new location for the BMP.

Step 7: Size Outlet Structure

7-1. The basin outlet pipe shall be sized, at a minimum, to pass flows greater than the stormwater quality design peak flow for off-line basins or flows greater than the peak runoff discharge rate for the 100-year, 24-hr design storm for on-line basins.

Step 8: Determine Emergency Spillway Requirements

8-1. For online basins, an emergency overflow spillway should be sized to pass flows greater than the design peak runoff discharge rate for the 100-yr, 24-hr storm to prevent overtopping of the walls or berms in the event that a blockage of the riser occurs. For offline basins, an emergency spillway or riser should be sized to pass the water quality design storm. For sites where the emergency spillway discharges to a steep slope, an emergency overflow riser, in addition to the spillway should be provided.

Design Example

Wet detention basin siting requires the following considerations prior to construction: (1) availability of base flow – wet detention basins require a regular source of water if water level is to be maintained, (2) surface space availability – large footprint area is required, and (3) compatibility with flood control – basins must not interfere with flood control functions of existing conveyance and detention structures.

The wet detention basin in this example does not have extended detention. An internal berm separates the forebay (Cell 1) and the main basin (Cell 2). The berm is at the elevation of the active volume design surface which is also the permanent wetpool elevation.

Step 1: Determine Water Quality Design Volume

For this design example, a 20-acre residential development with a 60% total impervious area is considered. The 85th percentile storm event for the project location is 0.75 inches.

Step 1: Determine water quality design volume	
1-1. Enter drainage area, A	A = 20 acres
1-2. Enter the maximum allowable percent of the Project area that may be effective impervious area (refer to permit), ranges from 5-30%, $\%_{allowable}$	$\%_{allowable} = 5$
1-3. Determine the maximum allowed effective impervious area, $EIA_{allowable} = (A_{project}) * (\%_{allowable})$	$EIA_{allowable} = 1.0$ acres
1-4. Enter Project impervious fraction, Imp (e.g. 60% = 0.60)	$Imp = 0.6$
1-5. Determine the Project Total Impervious area, $TIA = A_{project} * Imp$	$TIA = 12$ acres
1-6. Determine the total area from which runoff must be retained, $A_{retain} = TIA - EIA_{allowable}$	$A_{retain} = 11$ acres
1-7. Determine pervious runoff coefficient using Table E-1 , C_p	$C_p = 0.05$
1-8. Calculate runoff coefficient, $C = 0.95 * imp + C_p (1 - imp)$	$C = 0.59$
1-9. Enter design rainfall depth of the storm, P_i (in)	$P_i = 0.75$ in
1-10. Calculate rainfall depth, $P = P_i / 12$	$P = 0.06$ ft

1-11. Calculate water quality design volume, $SQDV = 43560 \cdot P \cdot A_{retain} \cdot C$	$SQDV = 17,000 \text{ ft}^3$
---	------------------------------

Step 2: Determine Active Design Volume for a Wet Detention Basin without Extended Detention

If there is no extended detention provided, wet detention basins shall be sized to provide a minimum wet pool volume equal to the water quality design volume plus an additional 5% for sediment accumulation.

Step 2: Determine Active Design Volume for a Wet Detention Basin without Extended Detention	
2-1. Calculate the active design volume (without extended detention), $V_a = 1.05 \cdot SQDV$	$V_a = 17,800 \text{ ft}^3$

Step 3: Determine Pond Location and Preliminary Geometry Based on Site Constraints

A total footprint area and total length available for the basin is provided. This step calculates the total active volume surface area which is equivalent to the permanent wetpool surface area. This step also calculates the dimensions of the internal berm.

Step 3: Determine Pond Location and Preliminary Geometry Based on Site Constraints	
3-1. Based on site constraints, determine the pond geometry and the storage available by developing an elevation-storage relationship for the pond. For this simple example, assume a trapezoidal geometry for cell 1 (forebay) and cell 2.	
3-2. Enter the total surface area of the pond footprint based on site constraints, A_{tot}	$A_{tot} = 7,500 \text{ ft}^2$
3-3. Enter the length of the pond footprint based on site constraints, L_{tot}	$L_{tot} = 150 \text{ ft}$
3-4. Calculate the width of the pond footprint, $W_{tot} = A_{tot} / L_{tot}$	$W_{tot} = 50 \text{ ft}$
3-5. Enter interior side slope as length per unit height (min = 3), Z	$Z = 3$

Step 3: Determine Pond Location and Preliminary Geometry Based on Site Constraints	
3-6. Enter desired freeboard depth, d_{fb} (1 ft min)	$d_{fb} = 2 \text{ ft}$
3-7. Calculate the length of the water quality volume surface area including the internal berm but excluding freeboard, $L_{av-tot} = L_{tot} - 2Zd_{fb}$	$L_{av-tot} = 138 \text{ ft}$
3-8. Calculate the width of the water quality volume surface area including the internal berm but excluding freeboard, $W_{av-tot} = W_{tot} - 2Zd_{fb}$	$W_{av-tot} = 38 \text{ ft}$
3-9. Calculate the total water quality volume surface area including the internal berm and excluding freeboard, $A_{av-tot} = L_{av-tot} \cdot W_{av-tot}$	$A_{av-tot} = 4,940 \text{ ft}^2$
3-10. Enter the width of the internal berm (6 ft min), W_{berm}	$W_{berm} = 6 \text{ ft}$
3-11. Enter the length of the internal berm, $L_{berm} = W_{av-tot}$	$L_{berm} = 38 \text{ ft}$
3-12. Calculate the area of the berm, $A_{berm} = W_{berm} \cdot L_{berm}$	$A_{berm} = 230 \text{ ft}^2$
3-13. Calculate the water quality volume surface area excluding the internal berm and freeboard, $A_{av} = A_{av-tot} - A_{berm}$	$A_{av} = 4,710 \text{ ft}^2$

Step 4: Determine Dimensions of forebay

It should be assumed that the forebay should be 5-10% of the total active design volume, V_a .

Step 4: Determine Dimensions of Cell 1	
4-1. Enter the percent of V_a in forebay (5-10% required), $\%V_1$	$\%V_1 = 20 \%$
4-2. Calculate the active volume of forebay (includes sediment storage volume), $V_1 = (V_a \cdot \%V_1) / 100$	$V_1 = 3,560 \text{ ft}^3$
4-3. Enter desired average depth of forebay (5-9 ft including sediment storage of 1 ft), d_1	$d_1 = 8 \text{ ft}$

4-4. Calculate the surface area for the active volume of forebay, $A_1 = V_1 / d_1$	$A_1 =$ 440 ft ²
4-5. Enter the width of forebay, $W_1 = W_{av-tot} = L_{berm}$	$W_1 =$ 38 ft
4-6. Calculate the length of forebay (<u>Note:</u> inlet and outlet should be configured to maximize the residence time), $L_1 = A_1 / W_1$	$L_1 =$ 12 ft

Step 5: Determine Dimensions of Cell 2

Verify that the surface area and length-to-width ratio of Cell 2 meet the design criteria. Calculate volumes, depths and surface areas for the emergent vegetation shallow zone and the deep zone.

Step 5: Determine Dimensions of Cell 2	
5-1. Calculate the active volume of Cell 2, $V_2 = V_a - V_1$	$V_2 =$ 14,200 ft ³
5-2. Determine minimum wetpool surface area, $A_{min2} = V_2 \cdot 0.3$	$A_{min2} =$ 4,270 ft ²
5-3. Determine actual wetpool surface area, $A_2 = A_{av} - A_1$	$A_2 =$ 4,270 ft ²
5-4. If A_2 is greater than A_{min2} then move on to step 5-5. If A_2 is less than A_{min2} , then modify input parameters to increase A_2 until it is greater than A_{min2} . If site constraints limit this criterion, then another site for the pond should be chosen.	
5-5. Enter width of Cell 2, $W_2 = W_1 = W_{av-tot} = L_{berm}$	$W_2 =$ 38 ft
5-6. Calculate top length of Cell 2, $L_2 = A_2 / W_2$	$L_2 =$ 110 ft
5-7. Verify that the length-to-width ratio of Cell 2 is at least 1.5:1 with $\geq 2:1$ preferred. If the length-to-width ratio is less than 1.5:1, modify input parameters until a ratio of at least 1.5:1 is achieved. If the input parameters cannot be modified as a result of site constraints, another site for the pond should be chosen, $LW_2 = L_2 / W_2$	$LW_2 =$ 2.9
5-8. Enter percent of surface area that will be planted with emergent vegetation (25-75%), $\%A_{ev}$	$\%A_{ev} =$ 25 %

Step 5: Determine Dimensions of Cell 2	
5-9. Calculate emergent vegetation surface area, $A_{ev} = (A_2 \cdot \%A_{ev})/100$	$A_{ev} = 1,070 \text{ ft}^2$
5-10. Enter average depth of emergent vegetation shallow zone (1.5 – 3 ft), d_{ev}	$d_{ev} = 2 \text{ ft}$
5-11. Calculate volume of emergent vegetation shallow zone (1.5 – 3 ft), $V_{ev} = A_{ev} \cdot d_{ev}$	$V_{ev} = 2,130 \text{ ft}^3$
5-12. Enter width of emergent vegetation shallow zone, $W_{ev} = W_2$	$W_{ev} = 38 \text{ ft}$
5-13. Calculate length of emergent vegetation shallow zone, $L_{ev} = A_{ev} / W_{ev}$	$L_{ev} = 56 \text{ ft}$
5-14. Calculate volume of deep zone, $V_{deep} = V_2 - V_{ev}$	$V_{deep} = 13,100 \text{ ft}^3$
5-15. Calculate surface area of deep (>3 ft) zone, $A_{deep} = A_2 - A_{ev}$	$A_{deep} = 3,200 \text{ ft}^2$
5-16. Calculate average depth of deep zone (4 - 8 ft), $d_{deep} = V_{deep} / A_{deep}$	$d_{deep} = 4.1 \text{ ft}$
5-17. Enter width of deep zone, $W_{deep} = W_2$	$W_{deep} = 28 \text{ ft}$
5-18. Calculate length of deep zone, $L_{deep} = A_{deep} / W_{deep}$	$L_{deep} = 114 \text{ ft}$

Step 6: Ensure Design Requirements and Site Conditions are Achieved

Check design requirements and site constraints. Modify design geometry until requirements are met. If the chosen site for the basin is inadequate to meet the design requirements, choose a new location for the BMP.

Step 7: Size Outlet Structure

The basin outlet pipe shall be sized, at a minimum, to pass flows greater than the stormwater quality design peak flow for off-line basins or flows greater than the peak runoff discharge rate for the 100-year, 24-hr design storm for on-line basins.

Step 8: Determine Emergency Spillway Requirements

For online basins, an emergency overflow spillway should be sized to pass flows greater than the design peak runoff discharge rate for the 100-yr, 24-hr storm to prevent overtopping of

the walls or berms in the event that a blockage of the riser occurs. For offline basins, an emergency spillway or riser should be sized to pass the water quality design storm. For sites where the emergency spillway discharges to a steep slope, an emergency overflow riser, in addition to the spillway should be provided.

E.10 TCM-3 Constructed Wetland

Sizing Methodology

In most cases, the constructed treatment wetland permanent pool shall be sized to be greater than or equal to the stormwater quality design volume. If extended detention is provided above the permanent pool and the wetland is designed for water quality treatment only, then the permanent pool volume shall be a minimum of 80 percent of the stormwater quality design volume and the surcharge volume (above the permanent pool) shall make up the remaining 20 percent and provide at least 12 hours of detention. If extended detention is provided and the basin is designed for water quality treatment and peak flow attenuation, then the permanent pool volume shall be equal to the water quality treatment volume and the surcharge volume shall be sized to attenuate peak flows to meet the peak runoff discharge requirements. The extended detention portion of the wetland above the permanent pool, if provided, functions like a dry extended detention (ED) basin (see [VEG-5: Dry Extended Detention Basin](#)).

Step 1: Calculate the design volume

Constructed wetlands shall be sized to be greater than or equal to the SQDV volume (see [Section 2](#) and Appendix E).

Step 2: Determine the Wetland Location, Wetland Type and Preliminary Geometry Based on Site Constraints

Based on site constraints, determine the wetland geometry and the storage available by developing an elevation-storage relationship for the wetland. The equations provided below assume a trapezoidal geometry for cell 1 (Forebay) and cell 2, and assumes that the wetland does not have extended detention.

- 1) Calculate the width of the wetland footprint, W_{tot} , as follows:

$$W_{tot} = \frac{A_{tot}}{L_{tot}} \quad \text{(Equation E-78)}$$

Where:

A_{tot} = total surface area of the wetland footprint (ft²)

L_{tot} = total length of the wetland footprint (ft)

- 12) Calculate the length of the water quality volume surface area including the internal berm but excluding the freeboard, L_{wq-tot} :

$$L_{wq-tot} = L_{tot} - 2Zd_{fb} \quad \text{(Equation E-79)}$$

Where:

Z = interior side slope as length per unit height

d_{fb} = freeboard depth

- 13) Calculate the width of the water quality volume surface area including the internal berm but excluding freeboard, W_{wq-tot} :

$$W_{wq-tot} = W_{tot} - 2Zd_{fb} \quad (\text{Equation E-80})$$

- 14) Calculate the total water quality volume surface area including the internal berm and excluding freeboard, A_{wq-tot} :

$$A_{wq-tot} = L_{wq-tot} \times W_{wq-tot} \quad (\text{Equation E-81})$$

- 15) Calculate the area of the berm, A_{berm} :

$$A_{berm} = W_{berm} \times L_{berm} \quad (\text{Equation E-82})$$

Where:

W_{berm} = width of the internal berm

L_{berm} = length of the internal berm

- 16) Calculate the water quality surface area excluding the internal berm and freeboard, A_{wq} :

$$A_{wq} = A_{wq-tot} - A_{berm} \quad (\text{Equation E-83})$$

Step 3: Determine Dimensions of Forebay

30-50% of the SQDV is required to be within the active volume of forebay.

- 1) Calculate the active volume of forebay, V_1 :

$$V_1 = \frac{SQDV \times \%V_1}{100} \quad (\text{Equation E-84})$$

Where:

$\%V_1$ = percent of SQDV in forebay (%)

- 2) Calculate the surface area for the active volume of forebay, A_1 :

$$A_1 = \frac{V_1}{d_1} \quad (\text{Equation E-85})$$

Where:

d_1 = average depth for the active volume of forebay (2 -4 ft) (ft)

- 3) Calculate the length of forebay, L_1 . Note, inlet and outlet should be configured to maximize the residence time.

$$L_1 = \frac{A_1}{W_1} \quad \text{(Equation E-86)}$$

Where:

$$W_1 = \text{width of forebay (ft), } W_1 = W_{av-tot} = L_{berm}$$

Step 4: Determine Dimensions of Cell 2

Cell 2 will consist of the remainder of the basin's active volume.

- 1) Calculate the active volume of Cell 2, V_2 :

$$V_2 = SQDV - V_1 \quad \text{(Equation E-87)}$$

- 2) Calculate the surface area of Cell 2, A_2 :

$$A_2 = A_{wq} - A_1 \quad \text{(Equation E-88)}$$

- 3) Calculate the top length of Cell 2, L_2 :

$$L_2 = \frac{A_2}{W_2} \quad \text{(Equation E-89)}$$

Where:

$$W_2 = \text{width of Cell 2 (ft), } W_2 = W_1 = W_{wq-tot} = L_{berm}$$

- 4) Verify that the length-to-width ratio of Cell 2, LW_2 , is at least 3:1 with $\geq 4:1$ preferred. If the length-to-width ratio is less than 3:1, modify input parameters until a ratio of at least 3:1 is achieved. If the input parameters cannot be modified as a result of site constraints, another site for the pond should be chosen.

$$LW_2 = \frac{L_2}{W_2} \quad \text{(Equation E-90)}$$

- 5) Calculate the very shallow zone surface area, A_{vs} :

$$A_{vs} = \frac{A_2 \cdot \%A_{vs}}{100} \quad \text{(Equation E-91)}$$

Where:

$$\%A_{vs} = \text{percent of surface area of very shallow zone}$$

- 6) Calculate the volume of the shallow zone, V_{vs} :

$$V_{vs} = A_{vs} \bullet d_{vs} \quad \text{(Equation E-92)}$$

Where:

d_{vs} = average depth of the very shallow zone (0.1 – 1 ft)

7) Calculate the length of the very shallow zone, L_{vs} :

$$L_{vs} = \frac{A_{vs}}{W_{vs}} \quad \text{(Equation E-93)}$$

Where:

W_{vs} = width of the very shallow zone (ft), $W_{vs} = W_2$

8) Calculate the surface area of the shallow zone, A_s :

$$A_s = \frac{A_2 \bullet \% A_s}{100} \quad \text{(Equation E-94)}$$

Where:

$\%A_s$ = percent of surface area of shallow zone

9) Calculate the volume of the shallow zone, V_s :

$$V_s = A_s \bullet d_s \quad \text{(Equation E-95)}$$

Where:

d_s = average depth of shallow zone (1 - 3 ft)

10) Calculate length of the shallow zone, L_s :

$$L_s = \frac{A_s}{W_s} \quad \text{(Equation E-96)}$$

Where:

W_s = width of the shallow zone (ft), $W_s = W_2$

11) Calculate the surface area of the deep zone, A_{deep} :

$$A_{deep} = A_2 - A_{vs} - A_s \quad \text{(Equation E-97)}$$

12) Calculate the volume of the deep zone, V_{deep} :

$$V_{deep} = V_2 - V_{vs} - V_s \quad \text{(Equation E-98)}$$

13) Calculate the average depth of the deep zone (3-5 ft), d_{deep} :

$$d_{deep} = \frac{V_{deep}}{A_{deep}} \quad \text{(Equation E-99)}$$

14) Calculate length of the deep zone, L_{deep} :

$$L_{deep} = \frac{A_{deep}}{W_{deep}} \quad \text{(Equation E-100)}$$

Where:

W_{deep} = width of the deep zone (ft), $W_{deep} = W_2$

Step 5: Ensure design requirements and site constraints are achieved

Check design requirements and site constraints. Modify design geometry until requirements are met. If the chosen site for the basin is inadequate to meet the design requirements, choose a new location or alternative treatment BMP.

Step 6: Size Outlet Structure

For wetlands with detention, the outlet structures shall be designed to provide 12 hours emptying time for the water quality volume or the required detention necessary for achieving the peak runoff discharge requirements if the extended detention is designed for flow attenuation.

The wetland outlet pipe shall be sized, at a minimum, to pass flows greater than the stormwater quality design peak flow for on-line basins or flows greater than the peak runoff discharge rate for the 100-year, 24-hr design storm for on-line basins.

Step 7: Determine Emergency Spillway Requirements

For online basins, an emergency overflow spillway should be sized to pass flows greater than the design peak runoff discharge rate for the 100-yr, 24-hr storm in order to prevent overtopping of the walls or berms in the event that a blockage of the riser occurs. For offline basins, an emergency spillway or riser should be sized to pass the 100-yr, 24-hr post-development peak storm water runoff discharge rate directly to the downstream conveyance system or another acceptable discharge point. For sites where the emergency spillway discharges to a steep slope, an emergency overflow riser, in addition to the spillway should be provided.

Sizing Worksheet

Step 1: Determine water quality design volume		
1-1. Enter drainage area, A	A =	acres
1-2. Enter the maximum allowable percent of the Project area that may be effective impervious area (refer to permit), ranges from 5-30%, $\%_{allowable}$	$\%_{allowable} =$	%
1-3. Determine the maximum allowed effective impervious area, $EIA_{allowable} = (A_{project}) * (\%_{allowable})$	$EIA_{allowable} =$	acres
1-4. Enter Project impervious fraction, Imp (e.g. 60% = 0.60)	Imp =	
1-5. Determine the Project Total Impervious area, $TIA = A_{project} * Imp$	TIA =	acres
1-6. Determine the total area from which runoff must be retained, $A_{retain} = TIA - EIA_{allowable}$	$A_{retain} =$	acres
1-7. Determine pervious runoff coefficient using Table E-1, C_p	$C_p =$	
1-8. Calculate runoff coefficient, $C = 0.95 * imp + C_p (1 - imp)$	C =	
1-9. Enter design rainfall depth of the storm, P_i (in)	$P_i =$	in
1-10. Calculate rainfall depth, $P = P_i / 12$	P =	ft
1-11. Calculate water quality design volume, $SQDV = 43560 * P * A_{retain} * C$	SQDV =	ft ³
Step 2: Determine Wetland Location, Wetland Type and Preliminary Geometry Based on Site Constraints		
2-1. Based on site constraints, determine the wetland geometry and the storage available by developing an elevation-storage relationship for the wetland. For this simple example, assume a trapezoidal geometry for cell 1 (forebay) and cell 2. The wetland does not have extended detention.		

2-2. Enter the total surface area of the wetland footprint based on site constraints, A_{tot}	$A_{tot} =$ ft ²
2-3. Enter the length of the wetland footprint based on site constraints, L_{tot}	$L_{tot} =$ ft
2-4. Calculate the width of the wetland footprint, $W_{tot} = A_{tot} / L_{tot}$	$W_{tot} =$ ft
2-5. Enter interior side slope as length per unit height (min = 3), Z	$Z =$
2-6. Enter desired freeboard depth, d_{fb}	$d_{fb} =$ ft
2-7. Calculate the length of the water quality volume surface area including the internal berm but excluding freeboard, $L_{wq-tot} = L_{tot} - 2Zd_{fb}$	$L_{wq-tot} =$ ft
2-8. Calculate the width of the water quality volume surface area including the internal berm but excluding freeboard, $W_{wq-tot} = W_{tot} - 2Zd_{fb}$	$W_{wq-tot} =$ ft
2-9. Calculate the total water quality volume surface area including the internal berm and excluding freeboard, $A_{wq-tot} = L_{wq-tot} \cdot W_{wq-tot}$	$A_{wq-tot} =$ ft ²
2-10. Enter the width of the internal berm (6 ft min), W_{berm}	$W_{berm} =$ ft
2-11. Enter the length of the internal berm, $L_{berm} = W_{wq-tot}$	$L_{berm} =$ ft
2-12. Calculate the area of the berm, $A_{berm} = W_{berm} \cdot L_{berm}$	$A_{berm} =$ ft ²
2-13. Calculate the water quality volume surface area excluding the internal berm and freeboard, $A_{wq} = A_{wq-tot} - A_{berm}$	$A_{wq} =$ ft ²
Step 3: Determine Dimensions of forebay	
3-1. Enter the percent of SQDV in forebay (30-50% required), $\%V_1$	$\%V_1 =$ %
3-2. Calculate the active volume of forebay (includes water quality volume + sediment storage volume),	$V_1 =$ ft ³

$V_1 = (\text{SQDV} \cdot \%V_1) / 100$	
3-3. Enter desired average depth of forebay ₁ (2-4 ft including sediment storage of 1 ft), d_1	$d_1 =$ ft
3-4. Calculate the surface area for the water quality volume of forebay, $A_1 = V_1 / d_1$	$A_1 =$ ft ²
3-5. Enter the width of forebay, $W_1 = W_{\text{av-tot}} = L_{\text{berm}}$	$W_1 =$ ft
3-6. Calculate the length of forebay (Note: inlet and outlet should be configured to maximize the residence time), $L_1 = A_1 / W_1$	$L_1 =$ ft
Step 4: Determine Dimensions of Cell 2	
4-1. Calculate the active volume of Cell 2, $V_2 = \text{SQDV} - V_1$	$V_2 =$ ft ³
4-2. Calculate surface area of Cell 2, $A_2 = A_{\text{wq}} - A_1$	$A_2 =$ ft ²
4-3. Enter width of Cell 2, $W_2 = W_1 = W_{\text{wq-tot}} = L_{\text{berm}}$	$W_2 =$ ft
4-4. Calculate top length of Cell 2, $L_2 = A_2 / W_2$	$L_2 =$ ft
4-5. Verify that the length-to-width ratio of Cell 2 is at least 3:1 with $\geq 4:1$ preferred. If the length-to-width ratio is less than 3:1, modify input parameters until a ratio of at least 3:1 is achieved. If the input parameters cannot be modified as a result of site constraints, another site for the pond should be chosen, $LW_2 = L_2 / W_2$	$LW_2 =$
4-6. Enter percent of surface area of very shallow zone, $\%A_{\text{vs}}$	$\%A_{\text{vs}} =$ %
4-7. Calculate very shallow zone surface area, $A_{\text{vs}} = (A_2 \cdot \%A_{\text{vs}}) / 100$	$A_{\text{vs}} =$ ft ²
4-8. Enter average depth of very shallow zone (0.1 - 1 ft), d_{vs}	$d_{\text{vs}} =$ ft
4-9. Calculate volume of very shallow zone, $V_{\text{vs}} = A_{\text{vs}} \cdot d_{\text{vs}}$	$V_{\text{vs}} =$ ft ³
4-10. Enter width of very shallow zone, $W_{\text{vs}} = W_2$	$W_{\text{vs}} =$ ft

4-11. Calculate length of very shallow zone, $L_{vs} = A_{vs} / W_{vs}$	$L_{vs} =$ ft
4-12. Enter percent of surface area of shallow zone, $\%A_s$	$\%A_s =$ %
4-13. Calculate surface area of shallow zone, $A_s = (A_2 \cdot \%A_s)/100$	$A_s =$ ft ²
4-14. Enter average depth of shallow zone (1 - 3 ft), d_s	$d_s =$ ft
4-15. Calculate volume of shallow zone, $V_s = A_s \cdot d_s$	$V_s =$ ft ³
4-16. Enter width of shallow zone, $W_s = W_2$	$W_s =$ ft
4-17. Calculate length of shallow zone, $L_s = A_s / W_s$	$L_s =$ ft
4-18. Calculate surface area of deep zone, $A_{deep} = A_2 - A_{vs} - A_s$	$A_{deep} =$ ft ²
4-19. Calculate volume of deep zone, $V_{deep} = V_2 - V_{vs} - V_s$	$V_{deep} =$ ft ³
4-20. Calculate average depth of deep zone (3 - 5 ft), $d_{deep} = V_{deep} / A_{deep}$	$d_{deep} =$ ft
4-21. Enter width of deep zone, $W_{deep} = W_2$	$W_{deep} =$ ft
4-22. Calculate length of deep zone, $L_{deep} = A_{deep} / W_{deep}$	$L_{deep} =$ ft
Step 5: Ensure Design Requirements and Site Constraints are Achieved	
5-1. Check design requirements and site constraints. Modify design geometry until requirements are met. If the chosen site for the wetland is inadequate to meet the design requirements, choose a new location for the wetland or select an alternative treatment BMP.	

Step 6: Size Outlet Structure

6-1. The wetland outlet pipe shall be sized, at a minimum, to pass flows greater than the stormwater quality design peak flow for off-line basins or flow from the capital storm for on-line basins.

Step 7: Determine Emergency Spillway Requirements

7-1. For online basins, an emergency overflow spillway should be sized to pass flows greater than the design peak runoff discharge rate for the 100-yr, 24-hr storm in order to prevent overtopping of the walls or berms in the event that a blockage of the riser occurs. For offline basins, an emergency spillway or riser should be sized to pass the 100-yr, 24-hr post-development peak storm water runoff discharge rate directly to the downstream conveyance system or another acceptable discharge point.

Design Example

Wetland siting requires the following considerations prior to construction: (1) availability of base flow – stormwater wetlands require a regular source of water to support wetland biota, (2) slope stability – stormwater wetlands are not permitted near steep slope hazard areas, (3) surface space availability – large footprint area is required, and (4) compatibility with flood control – basins must not interfere with flood control functions of existing conveyance and detention structures.

The wetland in this example does not have extended detention. An internal berm separates the forebay (Cell 1) and the main basin (Cell 2). The berm is at the elevation of the active volume (SQDV plus sediment storage volume) design surface which is also the permanent wetpool elevation.

Step 1: Determine Water Quality Design Volume

For this design example, a 20-acre residential development with a 60% total impervious area is considered. The 85th percentile storm event for the project location is 0.75 inches.

Step 1: Determine water quality design volume	
1-1. Enter drainage area, A	A = 20 acres
1-2. Enter the maximum allowable percent of the Project area that may be effective impervious area (refer to permit), ranges from 5-30%, % <i>allowable</i>	% <i>allowable</i> = 5
1-3. Determine the maximum allowed effective impervious area, $EIA_{allowable} = (A_{project}) * (\%allowable)$	$EIA_{allowable} = 1.0$ acres
1-4. Enter Project impervious fraction, <i>Imp</i> (e.g. 60% = 0.60)	<i>Imp</i> = 0.6
1-5. Determine the Project Total Impervious area, $TIA = A_{project} * Imp$	TIA = 12 acres
1-6. Determine the total area from which runoff must be retained, $A_{retain} = TIA - EIA_{allowable}$	$A_{retain} = 11$ acres
1-7. Determine pervious runoff coefficient using Table E-1 , <i>C_p</i>	<i>C_p</i> = 0.05
1-8. Calculate runoff coefficient, $C = 0.95 * imp + C_p (1 - imp)$	C = 0.59
1-9. Enter design rainfall depth of the storm, <i>P_i</i> (in)	<i>P_i</i> = 0.75 in

1-10. Calculate rainfall depth, $P = P_i/12$	P = 0.06 ft
1-11. Calculate water quality design volume, $SQDV = 43560 \cdot P \cdot A_{retain} \cdot C$	SQDV = 17,000 ft ³

Step 2: Determine Pond Location and Preliminary Geometry Based on Site Constraints

A total footprint area and total length available for the wetland is provided. This step calculates the total active volume surface area which is equivalent to the permanent wetpool surface area. This step also calculates the dimensions of the internal berm.

Step 2: Determine Wetland Location, Wetland Type and Preliminary Geometry Based on Site Constraints	
2-1. Based on site constraints, determine the wetland geometry and the storage available by developing an elevation-storage relationship for the wetland. For this simple example, assume a trapezoidal geometry for cell 1 (forebay) and cell 2. The wetland does not have extended detention.	
2-2. Enter the total surface area of the wetland footprint based on site constraints, A_{tot}	$A_{tot} = 7,500$ ft ²
2-3. Enter the length of the wetland footprint based on site constraints, L_{tot}	$L_{tot} = 200$ ft
2-4. Calculate the width of the wetland footprint, $W_{tot} = A_{tot} / L_{tot}$	$W_{tot} = 38$ ft
2-5. Enter interior side slope as length per unit height (min = 3), Z	$Z = 3$
2-6. Enter desired freeboard depth, d_{fb}	$d_{fb} = 2$ ft
2-7. Calculate the length of the water quality volume surface area including the internal berm but excluding freeboard, $L_{wq-tot} = L_{tot} - 2Zd_{fb}$	$L_{wq-tot} = 188$ ft
2-8. Calculate the width of the water quality volume surface area including the internal berm but excluding freeboard, $W_{wq-tot} = W_{tot} - 2Zd_{fb}$	$W_{wq-tot} = 26$ ft

Step 2: Determine Wetland Location, Wetland Type and Preliminary Geometry Based on Site Constraints	
2-9. Calculate the total water quality volume surface area including the internal berm and excluding freeboard, $A_{wq-tot} = L_{wq-tot} \cdot W_{wq-tot}$	$A_{wq-tot} = 4,900 \text{ ft}^2$
2-10. Enter the width of the internal berm (6 ft min), W_{berm}	$W_{berm} = 6 \text{ ft}$
2-11. Enter the length of the internal berm, $L_{berm} = W_{wq-tot}$	$L_{berm} = 26 \text{ ft}$
2-12. Calculate the area of the berm, $A_{berm} = W_{berm} \cdot L_{berm}$	$A_{berm} = 160 \text{ ft}^2$
2-13. Calculate the active volume surface area excluding the internal berm and freeboard, $A_{wq} = A_{wq-tot} - A_{berm}$	$A_{wq} = 4,740 \text{ ft}^2$

Step 3: Determine Dimensions of Forebay

It should be assumed that the forebay should be 30-50% of the SQDV.

Step 3: Determine Dimensions of forebay	
3-1. Enter the percent of SQDV in forebay (30-50% required), $\%V_1$	$\%V_1 = 30 \%$
3-2. Calculate the active volume of forebay (including sediment storage), $V_1 = (\text{SQDV} \cdot \%V_1)/100$	$V_1 = 5,100 \text{ ft}^3$
3-3. Enter desired average depth of forebay (2-4 ft including sediment storage of 1 ft), d_1	$d_1 = 4 \text{ ft}$
3-4. Calculate the surface area for the water quality volume of forebay, $A_1 = V_1 / d_1$	$A_1 = 1,275 \text{ ft}^2$
3-5. Enter the width of forebay, $W_1 = W_{av-tot} = L_{berm}$	$W_1 = 38 \text{ ft}$
3-6. Calculate the length of forebay (Note: inlet and outlet should be configured to maximize the residence time), $L_1 = A_1 / W_1$	$L_1 = 34 \text{ ft}$

Step 4: Determine Dimensions of Cell 2

Verify that the surface area and length-to-width ratio of Cell 2 meet the design criteria. Calculate volumes, depths and surface areas for the very shallow, shallow and deep zones.

Step 4: Determine Dimensions of Cell 2	
4-1. Calculate the active volume of Cell 2, $V_2 = \text{SQDV} - V_1$	$V_2 = 11,900 \text{ ft}^3$
4-2. Calculate surface area of Cell 2, $A_2 = A_{\text{wq}} - A_1$	$A_2 = 3,460 \text{ ft}^2$
4-3. Enter width of Cell 2, $W_2 = W_1 = W_{\text{wq-tot}} = L_{\text{berm}}$	$W_2 = 26 \text{ ft}$
4-4. Calculate top length of Cell 2, $L_2 = A_2 / W_2$	$L_2 = 130 \text{ ft}$
4-5. Verify that the length-to-width ratio of Cell 2 is at least 3:1 with $\geq 4:1$ preferred. If the length-to-width ratio is less than 3:1, modify input parameters until a ratio of at least 3:1 is achieved. If the input parameters cannot be modified as a result of site constraints, another site for the pond should be chosen, $LW_2 = L_2 / W_2$	$LW_2 = 5$
4-6. Enter percent of surface area of very shallow zone, $\%A_{\text{vs}}$	$\%A_{\text{vs}} = 15 \text{ ft}^2$
4-7. Calculate very shallow zone surface area, $A_{\text{vs}} = (A_2 \cdot \%A_{\text{vs}}) / 100$	$A_{\text{vs}} = 520 \text{ ft}^2$
4-8. Enter average depth of very shallow zone (0.1 - 1 ft), d_{vs}	$d_{\text{vs}} = 1 \text{ ft}$
4-9. Calculate volume of very shallow zone, $V_{\text{vs}} = A_{\text{vs}} \cdot d_{\text{vs}}$	$V_{\text{vs}} = 520 \text{ ft}^3$
4-10. Enter width of very shallow zone, $W_{\text{vs}} = W_2$	$W_{\text{vs}} = 26 \text{ ft}$
4-11. Calculate length of very shallow zone, $L_{\text{vs}} = A_{\text{vs}} / W_{\text{vs}}$	$L_{\text{vs}} = 20 \text{ ft}$
4-12. Enter percent of surface area of shallow zone, $\%A_{\text{s}}$	$\%A_{\text{s}} = 55$
4-13. Calculate surface area of shallow zone, $A_{\text{s}} = (A_2 \cdot \%A_{\text{s}}) / 100$	$A_{\text{s}} = 1,900 \text{ ft}^2$
4-14. Enter average depth of shallow zone (1 - 3 ft), d_{s}	$d_{\text{s}} = 3 \text{ ft}$
4-15. Calculate volume of shallow zone, $V_{\text{s}} = A_{\text{s}} \cdot d_{\text{s}}$	$V_{\text{s}} = 5,700 \text{ ft}^3$
4-16. Enter width of shallow zone, $W_{\text{s}} = W_2$	$W_{\text{s}} = 26 \text{ ft}$
4-17. Calculate length of shallow zone, $L_{\text{s}} = A_{\text{s}} / W_{\text{s}}$	$L_{\text{s}} = 220 \text{ ft}$

Step 4: Determine Dimensions of Cell 2	
4-18. Calculate surface area of deep zone, $A_{\text{deep}} = A_2 - A_{\text{vs}} - A_s$	$A_{\text{deep}} = 1,040 \text{ ft}^2$
4-19. Calculate volume of deep zone, $V_{\text{deep}} = V_2 - V_{\text{vs}} - V_s$	$V_{\text{deep}} = 5,680 \text{ ft}^3$
4-20. Calculate average depth of deep zone (3 - 5 ft), $d_{\text{deep}} = V_{\text{deep}} / A_{\text{deep}}$	$d_{\text{deep}} = 5 \text{ ft}$
4-21. Enter width of deep zone, $W_{\text{deep}} = W_2$	$W_{\text{deep}} = 26 \text{ ft}$
4-22. Calculate length of deep zone, $L_{\text{deep}} = A_{\text{deep}} / W_{\text{deep}}$	$L_{\text{deep}} = 40 \text{ ft}$

Step 5: Ensure Design Requirements and Site Conditions are Achieved

Check design requirements and site constraints. Modify design geometry until requirements are met. If the chosen site for the wetland is inadequate to meet the design requirements, choose a new location for the wetland or select an alternative treatment BMP.

Step 6: Size Outlet Structure

6-1. The wetland outlet pipe shall be sized, at a minimum, to pass flows greater than the stormwater quality design peak flow for off-line basins or flow from the capital storm for on-line basins.

Step 7: Determine Emergency Spillway Requirements

For online basins, an emergency overflow spillway should be sized to pass flows greater than the design peak runoff discharge rate for the 100-yr, 24-hr storm in order to prevent overtopping of the walls or berms in the event that a blockage of the riser occurs. For offline basins, an emergency spillway or riser should be sized to pass the 100-yr, 24-hr post-development peak storm water runoff discharge rate directly to the downstream conveyance system or another acceptable discharge point.

E.11 TCM-4 Sand Filters

Sizing Methodology

A sand filter is designed with two parts: (1) a temporary storage reservoir to store runoff, and (2) a sand filter bed through which the stored runoff must percolate. Usually the storage reservoir is simply placed directly above the filter, and the floor of the reservoir pond is the top of the sand bed. For this case, the storage volume also determines the hydraulic head over the filter surface, which increases the rate of flow through the sand.

Two methods are available for sizing sand filters: a simple method and a routing modeling method. The simple method uses standard values to define filter hydraulic characteristics for determining the sand surface area. This method is useful for planning purposes, for a first approximation to begin iterations in the detailed method, or when use of the detailed computer model is not desired or not available. The simple method very often results in a larger filter than the routing method.

Background

Sand filter design is based on Darcy's law:

$$Q = KiA \quad \text{(Equation E-101)}$$

Where:

- Q = water quality design flow (cfs)
- K = hydraulic conductivity (fps)
- A = surface area perpendicular to the direction of flow (ft²)
- i = hydraulic gradient (ft/ft) for a constant head and constant media depth, computed as follows:

$$i = \frac{h+l}{l} \quad \text{(Equation E-102)}$$

Where:

- h = average depth of water above the filter (ft), defined for this design as $d/2$
- d = maximum storage depth above the filter (ft)
- l = thickness of sand media (ft)

Darcy's law underlies both the simple and the routing methods of design. The filtration rate V , or more correctly, $1/V$, is the direct input in the sand filter design. The relationship between the filtration rate V and hydraulic conductivity K is revealed by equating Darcy's law and the equation of continuity, $Q = VA$. Specifically:

$$Q = KiA \quad \text{and} \quad Q = VA$$

$$\text{So,} \quad VA = KiA$$

$$\text{Or:} \quad V = Ki \quad \text{(Equation E-103)}$$

Where,

$$V = \text{filtration rate (ft/s)}$$

Note that $V \neq K$. That is, the filtration rate is not the same as the hydraulic conductivity, but they do have the same units (distance per time). K can be equated to V by dividing V by the hydraulic gradient i , which is defined above.

The hydraulic conductivity K does not change with head nor is it dependent on the thickness of the media, only on the characteristics of the media and the fluid. A design hydraulic conductivity of 1 inch per hour (2 feet per day) used in this simple sizing method is based on bench-scale tests of conditioned rather than clean sand (KCSWDM, 2005) and represents the average sand bed condition as silt is captured and held in the sand bed.

Unlike the hydraulic conductivity, the filtration rate V changes with head and media thickness, although the media thickness is constant in the sand filter design.

Simple Sizing Method

The simple sizing method does not route flows through the filter. It determines the size of the filter based on the simple assumption that inflow is immediately discharged through the filter as if there were no storage volume. An adjustment factor (0.7) is applied to compensate for the greater filter size resulting from this method. Even with the adjustment factor, the simple method generally produces a larger filter size than the routing method.

Step 1: Determine the water quality design volume

Sand filters should be sized to capture and treat the stormwater quality design volume (see [Section E.1](#)).

Step 2: Determine maximum storage depth of water

Determine the maximum water storage depth (d) above the sand filter. This depth is defined as the depth at which water begins to overflow the reservoir pond, and it

depends on the site topography and hydraulic constraints. The depth is chosen by the designer, but shall be 6 feet or less.

Step 3: Calculate the sand filter area

Determine the sand filter area using the following equation:

$$A_{sf} = \frac{V_{wq}RL}{Kt(h+L)} \quad \text{(Equation E-104)}$$

Where,

A_{sf}	=	surface area of the sand filter bed (ft ²)
V_{wq}	=	water quality design volume (ft ³)
R	=	routing adjustment factor (use $R = 0.7$)
L	=	sand bed depth (ft)
K	=	design hydraulic conductivity (use 2 ft/day)
t	=	drawdown time (use 1 day)
h	=	average depth of water above the filter (ft), (use $d/2$ with d from Step 1)

Routing Method

A continuous runoff model, such as US EPA's Storm Water Management Model (SWMM) Model, can be used to optimally size a sand filter. A continuous simulation model consists of three components: a representative long term period of rainfall data (≈ 20 years or greater) as the primary model input; a model component representing the tributary area to the sand filter that takes into account the amount of impervious area, soil types of the pervious area, vegetation, evapotranspiration, etc.; and a component that simulates the sand filter. Using this method, the filter should be sized to capture and treat the WQ design volume from the post-development tributary area.

The continuous simulation model routes predicted tributary runoff to the sand filter, where treatment is simulated as a function of the infiltrative (flow) capacity of the sand filter and the available storage volume above the sand filter. In a continuous runoff model such as SWMM, the physical parameters of the sand filter are represented with stage-storage-discharge relationships. Due to the computational power of ordinary desktop computers, long-term continuous simulations generally take only minutes to run. This allows the modeler to run several simulations for a range of sand filter sizes, varying either the surface area of the filter (and resulting flow capacity) or the storage capacity above the sand filter, or both. Sufficient

continuous model simulations should be completed so that results encompass the WQ design volume capture goal.

Model results should be plotted for both varying storage depths above the filter and for varying filter surface area (and resulting flow capacity) while keeping all other parameters constant. The resulting relationship of percent capture as a function of sand filter flow and storage capacity can be used to optimally size a sand filter based on site conditions and restraints.

In addition to continuous simulation modeling, routing spreadsheets and/or other forms of routing modeling that incorporate rainfall-runoff relationships and infiltrative (flow) capacities of sand filters may be used to size facilities. Alternative sizing methodologies should be prepared with good engineering practices.

Sizing Worksheet

Step 1: Determine water quality design volume	
1-1. Enter Project area (acres), $A_{project}$	$A_{project} =$ acres
1-2. Enter the maximum allowable percent of the Project area that may be effective impervious area (refer to permit), ranges from 5-30%, $\%_{allowable}$	$\%_{allowable} =$ %
1-3. Determine the maximum allowed effective impervious area (ac), $EIA_{allowable} = (A_{project}) * (\%_{allowable})$	$EIA_{allowable} =$ acres
1-4. Enter Project impervious fraction, Imp (e.g. 60% = 0.60)	$Imp =$
1-5. Determine the Project Total Impervious area (acres), $TIA = A_{project} * Imp$	$TIA =$ acres
1-6. Determine the total area from which runoff must be retained (acres), $A_{retain} = TIA - EIA_{allowable}$	$A_{retain} =$ acres
1-7. Determine pervious runoff coefficient using <u>Table E-1</u> , C_p	$C_p =$
1-8. Calculate runoff coefficient, $C = 0.95 * imp + C_p (1 - imp)$	$C =$
1-9. Enter design rainfall depth of the storm (in), P_i	$P_i =$ in
1-10. Calculate rainfall depth (ft), $P = P_i / 12$	$P =$ ft
1-11. Calculate water quality design volume (ft ³), $SQDV = 43560 \cdot C \cdot P \cdot A_{retain}$	$SQDV =$ ac-ft
Step 2: Determine maximum storage depth of water	
2-1. Determine the maximum storage depth (max 6 ft) of water above the sand filter, d (ft)	$d =$ ft

Step 3: Calculate sand filter area	
3-1. Enter water quality design volume, $SQDV$	$SQDV =$ ft ³
3-2. Enter routing adjustment factor (use $R = 0.7$), R	$R =$
3-3. Enter thickness of sand filter (min. 2 ft, 3 ft preferred), L	$L =$ ft
3-4. Enter design hydraulic conductivity of media (use 2 ft/day), K_{des}	$K =$ ft/day
3-5. Enter drawdown time, t	$t =$ day
3-6. Calculate average depth of water above the filter, $h = d/2$	$h =$ ft
3-7. Calculate sand filter area, $A_{sf} = (SQDV * RL) / (Kt (h + L))$	$A_{sf} =$ ft ²
Step 4: Determine filter dimensions	
4-1. Sand filter area, A_{sf}	$A_{sf} =$ ft ²
4-2. Enter geometric configuration, LR:W ratio (2:1 or greater), L_R	$L_R =$
4-3. Select the width of the sand filter, W	$W =$ ft
4-4. Calculate the length of the sand filter, $L = WL_R$	$L =$ ft
4-5. Calculate rate of filtration, $r_{wq} = K_i$; where $i = \frac{h + l}{l}$	$r_{wq} =$ ft/d
Step 5: Calculate filter longitudinal underdrain collection pipe	
5-1. Calculated filtered flow rate, $Q_f = r_{wq} A_{sf} / 86400$	$Q_f =$ cfs
5-2. Enter minimum slope for energy gradient, S_e	$S_e =$

5-3. Enter Hazen-Williams coefficient for plastic, C	$C =$
5-4. Enter pipe diameter (6" min.), D	$D =$ in
5-5. Calculate pipe hydraulic radius, $R_h = D/48$	$R_h =$ ft
5-6. Calculate velocity at the outlet of the pipe, $V_p = 1.318CR_h^{0.63}S_e^{0.54}$	$V_p =$ ft/s
5-7. Calculate pipe capacity, $Q_{cap} = 0.25\pi(D/12)^2V_p$	$Q_{cap} =$ cfs
Step 7: Provide conveyance capacity for filter clogging	
7-1. The sand filters should be placed off-line, but an emergency overflow must still be provided in the event the filter becomes clogged.	

Design Example

Step 1: Determine water quality design volume

For this design example, a 10-acre site with soil type 4 and 60% total impervious area is considered. The 85th percentile storm event for the project location is 0.75 inches.

Step 1: Determine water quality design volume	
1-1. Enter Project area (acres), $A_{project}$	$A_{project} = 10$ acres
1-2. Enter the maximum allowable percent of the Project area that may be effective impervious area (refer to permit), ranges from 5-30%, $\%_{allowable}$	$\%_{allowable} = 5$
1-3. Determine the maximum allowed effective impervious area (ac), $EIA_{allowable} = (A_{project}) * (\%_{allowable})$	$EIA_{allowable} = 0.5$ acres
1-4. Enter Project impervious fraction, Imp (e.g. 60% = 0.60)	$Imp = 0.6$
1-5. Determine the Project Total Impervious area (acres), $TIA = A_{project} * Imp$	$TIA = 6$ acres
1-6. Determine the total area from which runoff must be retained (acres), $A_{retain} = TIA - EIA_{allowable}$	$A_{retain} = 5.5$ acres
1-7. Determine pervious runoff coefficient using Table E-1 , C_p	$C_p = 0.05$
1-8. Calculate runoff coefficient, $C = 0.95 * imp + C_p (1 - imp)$	$C = 0.59$
1-9. Enter design rainfall depth of the storm (in), P_i	$P_i = 0.75$ in
1-10. Calculate rainfall depth (ft), $P = P_i / 12$	$P = 0.06$ ft
1-11. Calculate water quality design volume (ft ³), $SQDV = 43560 * C * P * A_{retain}$	$SQDV = 0.20$ ac-ft

Step 1a: Determine maximum storage depth of water

Determine the maximum storage depth of water above the sand filter.

Step 1a: Determine maximum storage depth of water	
1a-1. Determine the maximum storage depth (max 6 ft) of water above the sand filter, d (ft)	$d = 6 \text{ ft}$

Step 2: Calculate Sand Filter Area

A sand filter is designed with two components: (1) temporary storage reservoir to store runoff, and (2) a sand filter bed through which the stored runoff must percolate getting treatment.

The simple sizing method does not route flows through the filter. The size of the filter is determined based on the simple assumption that inflow is immediately discharged through the filter. The adjustment factor, R , is applied to compensate for the greater filter size resulting from this method.

Step 2: Calculate sand filter area	
2-1. Enter water quality design volume, $SQDV$	$SQDV = 0.20 \text{ ac-ft}$
2-2. Enter routing adjustment factor (use $R = 0.7$), R	$R = 0.7$
2-3. Enter thickness of sand filter (min. 2 ft, 3 ft preferred), L	$L = 2 \text{ ft}$
2-4. Enter design hydraulic conductivity (use 2 ft/day), K	$K = 2 \text{ ft/day}$
2-5. Enter drawdown time (use 1 day), t	$t = 2 \text{ day}$
2-6. Calculate average depth of water above the filter, $h = d/2$	$h = 3 \text{ ft}$
2-7. Calculate sand filter area, $A_{sf} = (SQDV * RL) / (Kt (h + L))$	$A_{sf} = 0.014 \text{ acre}$

Step 3: Determine Filter Dimensions

Step 3: Determine filter dimensions	
3-1. Sand filter area in ft^2 , $A_{sf(\text{feet})} = A_{sf(\text{acre})} * 43,560$	$A_{sf} = 610 \text{ ft}^2$
3-2. Enter geometric configuration, LR:W ratio (2:1 min.), L_R	$L_R = 2$
3-3. Calculate the width of the sand filter, W	$W = 18 \text{ ft}$

Step 3: Determine filter dimensions	
3-4. Calculate the length of the sand filter, L	$L = 36$ ft
3-5. Calculate rate of filtration, $r_{wq} = Ki$, where $i = \frac{h+l}{l}$	$r_{wq} = 2.3$ ft/d

Step 4: Calculate Filter Longitudinal Underdrain Collection Pipe

All underdrain pipes must be 6 inches or greater to facilitate cleaning.

Step 5: Calculate filter longitudinal underdrain collection pipe	
5-1. Calculated filtered flow rate, $Q_f = r_{wq}A_{sf}/86400$	$Q_f = 0.01$ cfs
5-2. Enter minimum slope for energy gradient, Se	$Se = 0.005$
5-3. Enter Hazen-Williams coefficient for plastic, C	$C = 140$
5-4. Enter pipe diameter (6" min), D	$D = 6$ in
5-5. Calculate pipe hydraulic radius, $R_h = D/48$	$R_h = 0.13$
5-6. Calculate velocity at the outlet of the pipe, $V_p = 1.318CR_h^{0.63}S_e^{0.54}$	$V_p = 2.9$ ft/s
5-7. Calculate pipe capacity, $Q_{cap} = 0.25\pi(D/12)^2V_p$	$Q_{cap} = 0.57$ cfs

Step 5: Provide Conveyance Capacity for Filter Clogging

The sand filters should be placed off-line, but an emergency overflow must still be provided in the event the filter becomes clogged.

APPENDIX F : FLOW SPLITTER DESIGN SPECIFICATIONS

F.1 Flow Splitter Introduction

Flow splitters must be provided for off-line facilities to divert the water quality design flow to the BMP and bypass higher flows. In most cases, it is a designer's choice whether storm water treatment BMPs described in this manual are designed as on-line or off-line; exceptions are vegetated strip filters, permeable pavement, and building BMPs which are designed on-line.

A crucial factor in designing flow splitters is to ensure that low flows are delivered to the treatment facility up to the water quality design flow rate. Above this rate, additional flows remain in the storm drain or are diverted to a bypass drain with minimal increase in head at the flow splitter structure to avoid surcharging the water quality facility under high flow conditions.

Flow splitters are typically manholes or vaults with baffles. In place of baffles, the splitter mechanism may be a half tee section with a solid top and an orifice in the bottom of the tee section. A full tee option may also be used (see "Design Criteria" below). Two possible design options for flow splitters are shown in the figures in this Appendix. Other equivalent designs that achieve the result of splitting low flows, up to the WQ design flow, into the WQ treatment facility and divert higher flows around the facility are also acceptable.

Flow splitters may be modeled using standard level pool routing techniques, as described in the Handbook of Applied Hydrology (Ven te Chow; 1964) and elsewhere. The stage/discharge relationship of the outflow pipes shall be determined using backwater analysis techniques. Weirs shall be analyzed as sharp-crested weirs.

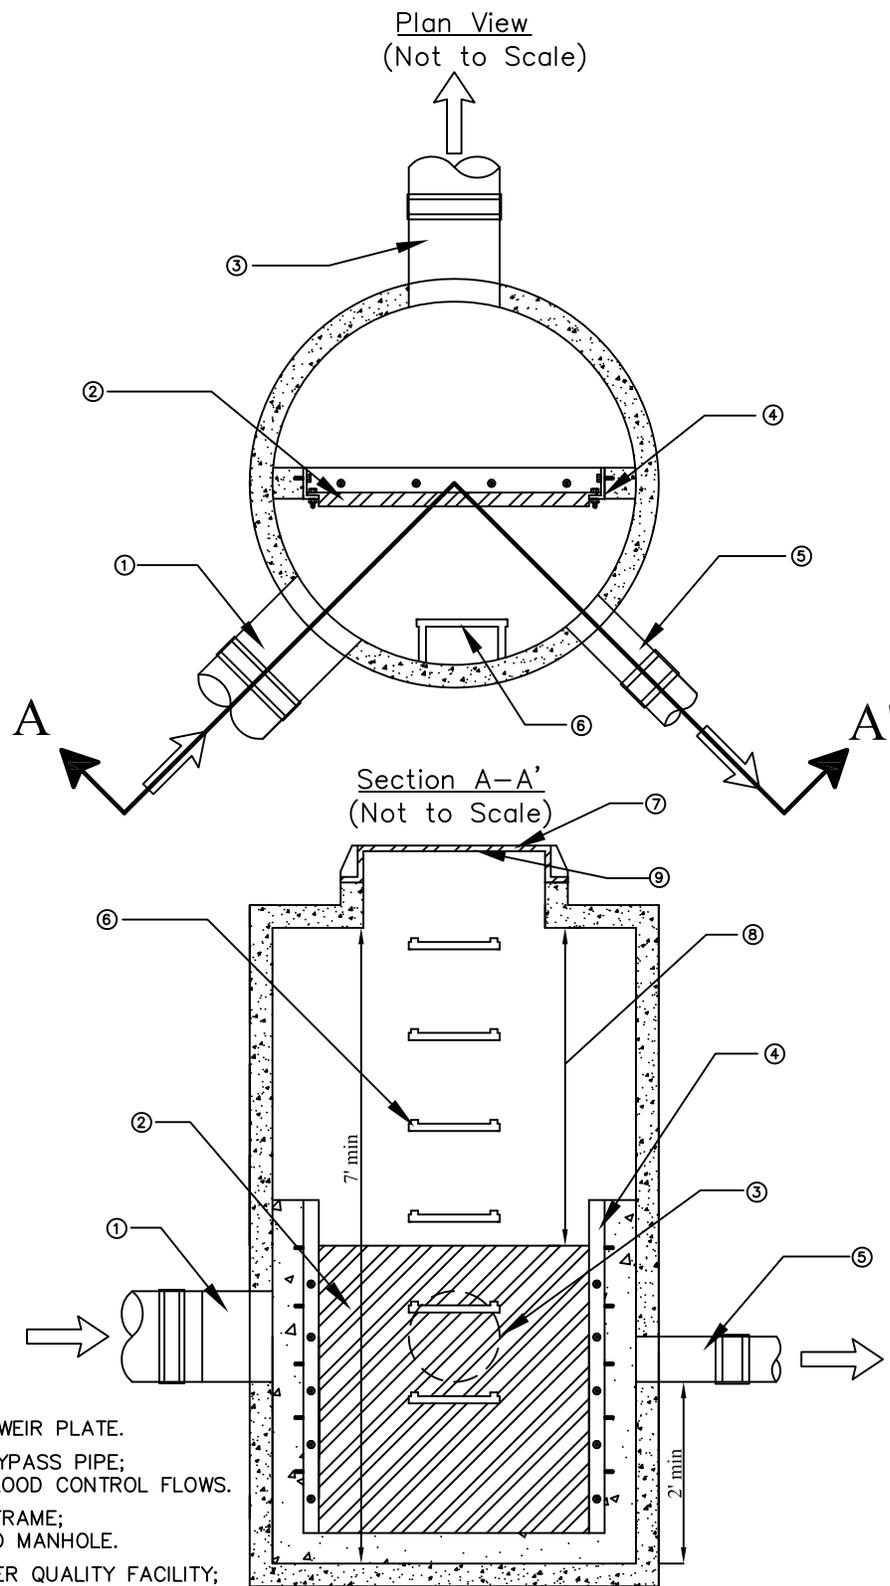

Design Criteria

- 1) A flow splitter shall be designed to deliver the required water quality design flow rate to the storm water treatment facility.
- 17) The top of the weir shall be located at the water surface for the design flow. Remaining flows enter the bypass line.
- 18) The maximum head shall be minimized for flow in excess of the water quality design flow. Specifically, flow to the treatment facility at the flood control design storm water surface shall not increase the design water quality design flow by more than 10%.
- 19) Example designs are shown in the figures in this Appendix. Equivalent designs are also acceptable.
- 20) Special applications, such as roads, may require the use of a modified flow splitter. The baffle wall may be fitted with a notch and adjustable weir plate to proportion runoff volumes other than high flows.

- 21) For ponding facilities, backwater effects must be included in designing the height of the standpipe in the manhole.
- 22) Ladder or step and handhold access shall be provided. If the weir wall is higher than 36 inches, two ladders, on the either side of the wall, are required.

F.2 Material Requirements

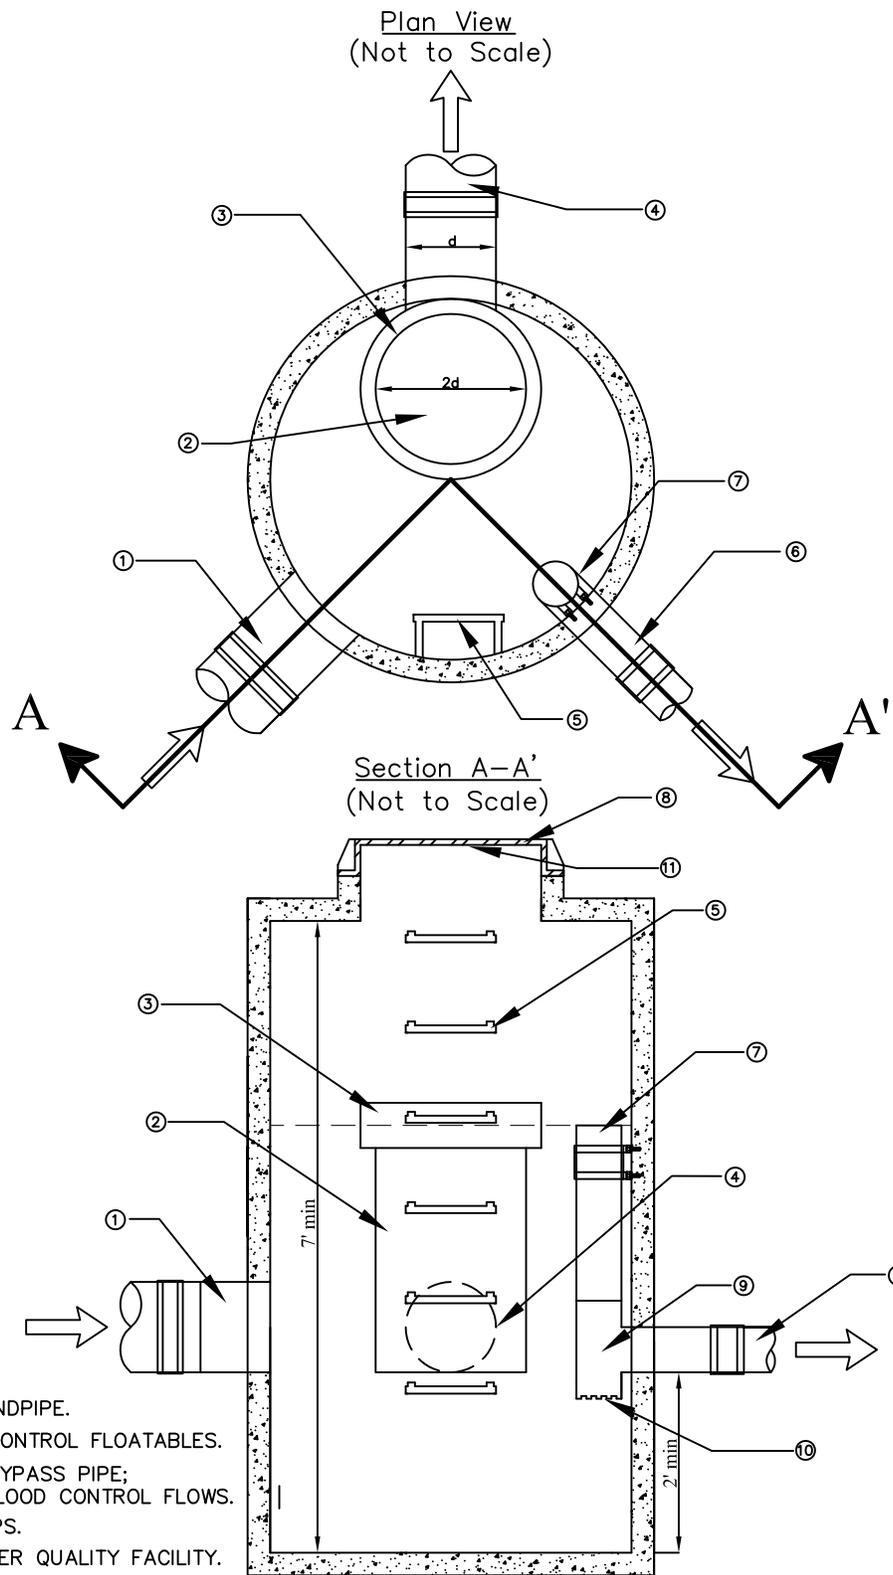

- 1) The splitter baffle shall be installed in a standard manhole or vault. The baffle wall shall be made of material resistant to corrosion (minimum 4-inch thick reinforced concrete, Type 302 or Type 316 stainless steel plate, or equivalent).
- 23) The minimum clearance between the top of the baffle wall and the bottom of the manhole or vault cover shall be 4 feet; otherwise, dual access points shall be provided.
- 24) All metal parts shall be corrosion resistant. Examples of preferred materials include aluminum, stainless steel, and plastic. Zinc and galvanized materials are not permitted because of aquatic toxicity. Painting metal parts shall not be allowed because of poor longevity.

NOTES:

- ① INLET PIPE.
- ② ADJUSTABLE WEIR PLATE.
- ③ HIGH FLOW BYPASS PIPE; SIZED FOR FLOOD CONTROL FLOWS.
- ④ WEIR PLATE FRAME; ANCHORED TO MANHOLE.
- ⑤ PIPE TO WATER QUALITY FACILITY; SIZED FOR WATER QUALITY FLOWS.
- ⑥ ACCESS STEPS.
- ⑦ 24" ROUND FRAME AND SOLID LID.
- ⑧ 4' MIN DISTANCE OR PROVIDE SEPARATE ACCESS ON BOTH SIDES OF WEIR.
- ⑨ AFFIX PERMANENT IDENTIFICATION TAG.

<p>Figure F-1: Flow Splitter Option A</p>

NOTES:

- ① INLET PIPE.
- ② BYPASS STANDPIPE.
- ③ BAFFLE TO CONTROL FLOATABLES.
- ④ HIGH FLOW BYPASS PIPE; SIZED FOR FLOOD CONTROL FLOWS.
- ⑤ ACCESS STEPS.
- ⑥ PIPE TO WATER QUALITY FACILITY.
- ⑦ RISER PIPE; TOP OF PIPE AT DESIGN ELEVATION FOR WATER QUALITY FLOWS.
- ⑧ 24" ROUND FRAME AND SOLID LID.
- ⑨ REMOVABLE "TEE" SECTION FOR CLEANOUT.
- ⑩ RISER PIPE ORIFICE SIZED FOR WATER QUALITY FLOWS.
- ⑪ AFFIX PERMANENT IDENTIFICATION TAG.

<p>Figure F-2: Flow Splitter Option B</p>

APPENDIX G: DESIGN CRITERIA CHECKLISTS FOR STORMWATER RUNOFF BMPS

BIO-1 Bioretention Checklist

- Has the bioretention facility been sized to treat the water quality design volume, SQDV (see worksheet)?
- Does the bioretention have a maximum ponding depth of 18 in.?
- Is the planting soil depth at least 2 feet?
- Has an underdrain been provided if native soil permeability is less than 0.5 in/hr and infiltration is not possible/allowed?
- Has a gravel drainage layer been provided if native soil permeability is greater than 0.5 in/hr and infiltration is possible/allowed?
- Does the bioretention ponding depth drain below the planting soil in less than 48 hours?
- Is the gravel drainage layer sized to adequately meet the maximum drawdown time of 96 hours?
- Has the bioretention facility been properly sized as recommended in the manual?
- Does the flow entrance meet specifications (dispersed, low velocity flow; dispersed flow across pavement; flow spreading trench; cuts or wheel slots for parking lots)?
- Does the pipe flow entrance include erosion protection material to dissipate flow energy?
- Is the flow path unblocked by trees and shrubs?
- Is the underdrain at least 6 inches in diameter?
- Is the underdrain pipe made of accepted material (slotted PVC pipe conforming to ASTM C 3034 or equivalent HDPE pipe conforming to AASHTO 252M)?
- Does the slotted pipe have correct sizing and spacing of slots?
- Is the underdrain sloped at 0.5% or more?
- Are rigid observation pipes connected to underdrain every 250 to 300 feet of installed pipe?
- Do the observation pipe wells/clean outs extend 6 inches above top elevation of bioretention facility mulch and are they capped as required?

- Does the gravel underdrain bedding consist of the correct aggregate?
- If geotextile fabric is placed between the planting media and gravel layer, does it meet the specifications outlined in the manual?
- Does the gravel underdrain bedding extend at least 6 inches below the underdrain pipe (if needed) and does it provide 1 foot depth around top and sides of pipe?
- Does the underdrain drain freely to the accepted discharge point?
- Is an overflow device consisting of vertical PVC pipe included in design?
- Has the overflow device been installed at the 18-inch ponding depth?
- Is the overflow riser at least 6 inches in diameter?
- Has the inlet to the riser been positioned at least 6 inches above the planting media and capped with a spider cap?
- If bioretention is close to roads or infrastructure, have infiltration pathways been restricted with geomembrane (at least 30 mm) or clay liners?
- Is planting soil composed of correct aggregate (60-70% sand; 30-40% compost) and free of stones, stumps and roots?
- Does compost have acceptable characteristics?
- Is constructed bioretention facility covered with well-aged mulch, free of seeds, weeds, soil and roots, and at least 2-3 inches thick?
- Is all bioretention vegetation tolerant of summer drought, ponding fluctuations, and saturated soil conditions for 48 to 72 hours?
- Have an adequate number of different plant species been incorporated into the bioretention (It is recommended that 3 tree, 3 shrub, and 3 herbaceous groundcover species be included)?
- Have native plants been used to the maximum extent practicable?

BIO- 2 Planter Box Checklist

- Is the planter box tributary area less than 15,000 ft²?
- Is the groundwater level at least 2 feet below the bottom of the planter box?
- Is there adequate relief between land surface and stormwater conveyance system to permit vertical percolation?
- Is the planter box located in an area with adequate sunlight to support selected vegetation?
- Is the planter box sized to treat the water quality design volume, V_{wq} (see worksheet)?
- Does the planter box have a maximum ponding depth of 12 inches?
- Is the planting soil depth at least 2 feet (3 feet preferred)?
- Does the ponded water drain below the planting soil in less than 48 hours?
- Has the distance between the downspouts and the overflow outlet been maximized?
- Has the planter box been sized the same as a Bioretention facility with planter box parameters?
- Has the planter box been constructed with an appropriate non-leaching permanent material?
- Has the planter box structure been adequately sealed to ensure that water exits only via the underdrain?
- Has an underdrain been provided?
- If the entrance to the planter box is piped, has erosion protection been included in the design (erosion protection includes rock, splash blocks, etc.)?
- Is the entrance flow path unimpeded by woody plants (trees, shrubs)?
- Is the underdrain at least 6 inches in diameter?
- Is the underdrain pipe made of accepted material (slotted PVC pipe conforming to ASTM C 3034 or equivalent HDPE pipe conforming to AASHTO 252M)?
- Does the slotted pipe have correct sizing and spacing of slots?
- Is the underdrain sloped at 0.5% or more?

- Are rigid observation pipes connected to underdrain every 250 to 300 feet of installed pipe?
- Do the observation pipe wells/clean outs extend 6 inches above top elevation of the planter box mulch and are they capped as required?
- Does the gravel underdrain bedding consist of the correct aggregate?
- Does the gravel underdrain bedding extend at least 6 inches below the underdrain and does it provide 1 foot depth around top and sides of pipe?
- If geotextile fabric is used in the underdrain design, does it meet minimum materials requirements?
- Is the underdrain elevated from the bottom of the planter box by 6 inches?
- Does the underdrain drain freely to the intended discharge point?
- Is an overflow device consisting of vertical PVC pipe included in design?
- Is the overflow riser at least 6 inches in diameter?
- Is the inlet to the riser 6 inches above planting soil and capped with a spider cap?
- Has a waterproof barrier consisting of a 30 mil geomembrane or equivalent been provided to protect foundations from moisture?
- Is planting soil composed of correct aggregate (60-70% sand; 30-40% compost) and gradation, and free of stones, stumps and roots?
- Does compost have acceptable characteristics (see planting/storage media)?
- Is planter box covered with well-aged mulch, free of seeds, weeds, grass clippings, bark, soil and roots, and at least 2-3 inches thick?
- Do all soil minerals meet requirements?
- Is all planter box vegetation tolerant of summer drought, ponding fluctuations, and saturated soil conditions for 48 to 72 hours?
- Have an adequate number of different plant species been incorporated into the planter box design (It is recommended that 3 tree, 3 shrub, and 3 herbaceous groundcover species be included)?
- Have native plants been used to the maximum extent practicable?
- Have only slow-release fertilizers been included in the design?
- Have arrangements been made to replace planter box mulch layer annually?

- Have low-maintenance plants been selected for design?
- Has an effort been made to ensure that no treated wood or galvanized metal is used anywhere within the planter box design?

BIO-3 Proprietary Biotreatment Device Checklist

- Has the proprietary biotreatment device been selected from the list provided in the manual or from another Ventura County- approved list?
- Has the vendor been contacted for the latest design guidance on cartridge selection?
- Has the proprietary biotreatment device been installed as directed by the vendor?
- Have appropriate maintenance and operation arrangements been made to ensure upkeep of the device?
- Has the biotreatment device been sized to capture and treat the water quality design flow?

BIO-4 Vegetated Swale Checklist

- Does the climate provide adequate conditions for maintaining a vegetative cover? Has adequate vegetation been chosen given the climate?
- Is the grade in the area shallow so as to not allow ponding?
- Is the swale compatible with existing flood control functions?
- Has the swale been designed with a depth of one foot or less?
- Is the overall depth from the top of the side walls to the bottom of the swale at least 12 inches?
- Is the swale bottom width at least 2 feet?
- Is the swale bottom width no greater than 10 feet, or 16 feet with a dividing berm?
- If the swale is required to convey flood flows in addition to the water quality design flow, has the swale been designed for the flood control design storm and does it include 2 feet of freeboard?
- Have gradual meandering bends been incorporated into the design?
- Is the longitudinal slope (in direction of flow) between 1% and 6%?
- Has an underdrain been provided if soils are poorly drained and longitudinal slope is less than 1.5%? Has a soils report been provided if this is the case?
- If the longitudinal slope is greater than 6%, have appropriate check dams with vertical drops of 12 inches or less been provided in the design to reduce the slope?
- Is the horizontal slope at the bottom of the swale flat to discourage channeling?
- Has the swale been designed so that the water depth does not exceed 4 inches or $\frac{2}{3}$ the height of vegetation (2 inches in frequently mowed turf swales)?
- Does the swale length provide a minimum hydraulic residence time of 7 minutes?
- If soil and slope conditions require it, has an acceptable low flow drain been installed?
- Has the swale been designed to convey the SQDF?

- Has the swale been sized as recommended in Chapter 6 (also see worksheet, Appendix E)?
- Has the swale been designed as a flow-through channel or has a high-flow bypass been incorporated into the design for flows higher than the water quality design flow?
- Has inflow been directed towards the upstream end of the swale or, at a minimum, evenly over the length of the swale?
- If the swale is online, has it been designed to convey flows up to the post-development 100 year 24 hour storm, with freeboard, and velocities below 3 ft/s?
- If the swale is off-line, has it been designed to convey the water quality design flow rate using a flow splitter with velocities below 1 ft/s?
- If check dams are incorporated in the design, have flow spreaders been added at the toe of each vertical drop?
- If curb cuts are used, has pavement been placed 1 – 2 inches above the elevation of the vegetated area?
- Is the swale inflow designed to function long term with minimal maintenance?
- Has flow spreading at the inlet of the swale been achieved by a leveled anchored flow spreader or similar method?
- Does the flow spreader project a minimum of 2 inches above the ground surface with appropriately spaced notches and extend horizontally beyond facility to prevent erosion
- If an underdrain is required, does it meet appropriate criteria (PVC or equivalent, correct slot spacing and sizing, 6 inches minimum in diameter, sloped at 0.5%)?
- Is there gravel bedding at least 6 inches below and 1 foot to the top and sides of the underdrain?
- If a geotextile is included in the design, does it meet requirements?
- Does gravel drainage layer meet recommended criteria?
- Does swale divider, if included, meet criteria (minimum height of 1 inch above flow, slopes no steeper than 2H:1V, stable foundation)?

APPENDIX G: DESIGN CRITERIA CHECKLISTS

- Has swale soil been amended with compost if organic content is less than 10%?
- Have appropriate, hardy and native plants been used to the maximum extent practical?
- Is vegetative cover at least 4 inches in height (ideally 6 inches)?
- Has the swale been located away from trees that may drop leaves or provide insufficient sunlight?

BIO-5 Vegetated Filter Strip Checklist

- Is the slope of the filter strip designed to avoid both erosive flows and ponding?
- Has the strip been designed to evenly distribute flow across width and promote sheet flow?
- Does the width of the filter strip extend across the full width of the tributary area?
- Is the upstream boundary of the filter located contiguous to developed area?
- If filter strip is used for water quality purposes, is the length between 15 and 150 feet (25 feet preferred)? If the strip is used for pretreatment, is it at least 4 feet in length?
- Is the slope of the strip parallel to the direction of flow between 2% and 6%?
- Is the lateral slope (perpendicular to flow) of the strip 4% or less?
- Is grading across strip even?
- Has the top of the strip been installed 2 to 5 inches below any adjacent pavement (a beveled transition is also acceptable)?
- Are the top and toe of the slope as flat as possible (graded flat for engineered filter strips) to encourage sheet flow and prevent erosion?
- Has the design flow been calculated using the SQDF (see worksheet)?
- Has the design flow depth been calculated using a modified Manning's equation (see worksheet)?
- Have the design velocity and length been calculated using the design flow and design flow depth as recommended (see worksheet)?
- Has a flow spreader been implemented to uniformly distribute contributing flow along width of filter strip?
- If a gravel flow spreader is used, is it at least 6 inches deep, 12 inches wide and a minimum of 1 inch below the paved surface?
- Has the gravel flow spreader been leveled even where ground is not level?
- If the gravel flow spreader is placed along a roadway, have LA county design specifications been consulted and implemented?

APPENDIX G: DESIGN CRITERIA CHECKLISTS

- If a notched curb spreader and through-curb spreader are used, have they been used in conjunction with a gravel spreader?
- Have curb port/interrupted curb openings been spaced at intervals of at least every 6 feet?
- Do the curb port/interrupted curb openings have a width of at least 11 inches?
- Does 15% or more of the curb length consist of open ports and does each port discharge no more than 10% of the flow?
- Have energy dissipaters (such as a riprap pad) been used if a sudden slope drop occurs?
- Has access been provided at the upper edge of filter strip for mowing equipment and to enable maintenance of spreader?
- Is the design water depth 1 inch or less?
- Does the design velocity not exceed 1 foot per second?
- If the organic content of the filter strip soil does not exceed 10%, has the soil been amended with at least 2 inches of well-rotted acceptable compost at a depth of 6 inches?
- Is filter strip uniformly graded and densely vegetated with erosion-resistant grasses (preferably native or adapted species)?
- Has irrigation been provided to establish grasses?
- Have maintenance arrangements been made to maintain grass at a height of 2 to 4 inches?
- Have trees and shrubs been limited along the filter strip?
- Has an effort been made to ensure that no treated wood or galvanized metal is used anywhere within the design?

BIO-6 Green Roof Checklist

- Is the roof shallow enough to support a green roof (<25% slope)?
- Are the roof supports sufficient to support additional weight of soil, water, vegetation, and a drainage layer (if needed) [a licensed structural engineer should be consulted]?
- Has an appropriate waterproof membrane been placed below the green roof?
- Has an appropriate drainage layer been incorporated in the design (if required)?
- Has an appropriate soil mix been used in the design to allow for drainage, support vegetative growth, and that is not excessively heavy when wet?
- Has vegetation been carefully selected to improve aesthetics, resist erosion, withstand extreme environments, and tolerate drought without the need for fertilizers and pesticides and without a lot of maintenance requirements (see Appendix H for a recommended plant list)?
- Have native plants been chosen to the maximum extent practical?
- If trees or shrubs are incorporated, has an adequate soil depth been provided and is the additional soil depth supported by the roof structure?
- Has irrigation been provided to establish vegetation?
- Does vegetation cover 90% of the total area?
- Is the green roof located in an area without excessive shade to avoid poor vegetative growth?
- Is there an appropriate drain pipe or gutter to convey any runoff from roof to a stormwater BMP or stormwater conveyance system?

FILT-1 Sand Filter Checklist

- Has sand filter been located away from trees and areas that could contribute eroded sediment?
- If there is a chance for sediment to be present in flow to be treated, has pretreatment been provided?
- Does site have adequate relief to permit vertical percolation through sand filter and into conveyance system?
- Has pretreatment (vegetated swale or filter strip, hydrodynamic separator) been adequately provided to reduce the sediment load entering the filter?
- Has the sand filter been sized to capture the SQDV?
- Has the sand filter been designed with a 1.5:1 length to width ratio or greater?
- Is the filter bed depth at least 2 feet (3 feet preferred)?
- Is the depth of water storage over the filter bed 6 feet or less?
- Is the overflow structure designed to pass the water quality design storm?
- Has the sizing of the filter been determined using the adapted Darcy's Law equation recommended in the sizing methodology section in Chapter 6 (also see worksheet, Appendix E)?
- Does the sand meet the recommended specifications (0.2-0.35 mm diameter, $C_u < 3$, ASTM C 33 size gradation, etc.)?
- Has an underdrain been employed in the design? [Examples: central underdrain w/lateral pipes, longitudinal pipes, single pipe for small filters]
- Is the underdrain placed in an 8 inch minimum gravel backfill or drain rock bed?
- Are all underdrain pipes and connectors 6 inches or greater with clean-out risers of equal diameter?
- Have clean-out risers been placed at the terminal ends of all pipes and extend to the surface of the filter?
- Has a valve box been provided for access to the clean-outs and is it water tight?
- Are underdrain pipes laid with perforations downward, and are perforations at least 1/2 inch in diameter?

- Are all lateral collection pipes within 9 feet or less of each other (perpendicular distance)?
- Have all pipes been placed with a minimum slope of 0.5%?
- Is the invert of the underdrain outlet above the seasonal high groundwater level?
- Is gravel backfill present around the underdrain pipe at least 6 inches below and to the sides of the pipe and 8 inches above the pipe?
- Does the bottom gravel have a diameter of at least 2 times the size of the perforated openings to the drainage system and meet other specifications (specific gravity of 2.5 or more, rounded, free of debris)?
- Has an appropriate geotextile layer (see underdrain section) or 2-inch transition layer been placed between the sand layer and the drain rock/gravel backfill layer?
- Has a flow spreader been installed at the inlet along one side of the filter (long side of the filter if L: W is 2:1 or greater; 20% of perimeter for curved or irregular shape)?
- Has erosion protection been provided along the first foot of the sand bed adjacent to the flow spreader (i.e. geotextile weighted with sand bags; quarry spalls)?
- Has no topsoil, clay, or sod (except sod grown in sand) has been added to the sand filter bed?
- Has vegetation been selected properly (i.e. must withstand drought, heavy saturation, etc.)?
- Are no permanent structures built on top of the sand filter bed?
- No large shrubs or trees should be planted in sand filter bed or within 15 feet of inlet or outlet pipes
- Have native plants been used to the maximum extent practicable?
- Has an emergency overflow structure been provided?
- Are interior side slopes above water quality design depth no steeper than 3:1 H:V?
- Are exterior side slopes no steeper than 2:1 H:V?
- If pond walls are vertical retaining walls, do they meet recommended specifications (see side slopes section)?

APPENDIX G: DESIGN CRITERIA CHECKLISTS

- Do embankments meet appropriate criteria [top width or 20 feet, constructed on native consolidated soil, in accordance with standard specifications, proper excavation, constructed of appropriate compacted soil]?
- Are maintenance access roads/ramps to filter provided?
- Have trees and shrubs been planted further than 10 feet away from inlet and outlet pipes (50 feet for 'water-seeking' plants such as willows and poplars)?
- Have prohibited non-native plants been removed from the site?
- Has an effort been made to ensure that no treated wood or galvanized metal is used anywhere within the planter box design?

FILT-2 Cartridge Media Filter

- Has the vendor been contacted for the latest design guidance on cartridge selection?
- Has the cartridge media filter been provided with a system to completely drain the system and prevent vector annoyances?
- Has the cartridge media filter been sized to capture and treat the SQDF?
- Have site considerations been taken into account when sizing the cartridge media filter and selecting features (often vendor websites offer assistance with this)?

INF-1 Infiltration Trench Checklist

- Has the infiltration trench been located away from steep slopes (>25%)?
- Is the infiltration trench set back from structures and leach fields?
- Is there at least 10 feet or vertical separation between the bottom of the infiltration trench and the shallow groundwater table?
- Is the depth to bedrock adequate to provide proper infiltration?
- Has the site been checked to ensure that no preexisting contamination is present?
- Does the site have low sediment loading rates to prevent infiltration trench clogging?
- Has a soil assessment report been completed, which determines the suitability of the site for an infiltration trench, recommends a design infiltration rate, identifies the high depth to groundwater table surface elevation, and examines how the stormwater runoff will move in the soil?
- Has a geotechnical investigation and report been provided if needed?
- Has the infiltration trench been located at a site that does not receive run off from sites that store or use chemicals or hazardous waste outside?
- Has the infiltration trench been set back from existing septic system drain fields and drinking water wells?
- Has pretreatment been provided with a vegetated swale, filter strip, sand filter or proprietary device?
- Is the trench at least 2 feet wide and 3 to 5 feet deep?
- Is the longitudinal slope of the trench 3% or less?
- Is the top layer of the media filter gravel/choking stone/geotextile fabric if flow is sheet flow and 12 inches of surface soil if flow enters through an underground pipe?
- Is middle layer of media filter 3-5 feet of washed 1.5 to 3 in. gravel with void space of 30 to 40%?
- Is bottom layer of media filter 6" of clean, washed sand?
- Have one or more observation wells been installed?

- Do observation wells consist of recommended slotted 4-6 inch diameter PVC well screen capped with lockable, above-ground lid?
- Has the infiltration trench been sized to capture and infiltrate the SUSMP defined water quality design volume?
- Has the infiltration trench been designed to infiltrate all runoff within 72 hours?
- Has the maximum depth of runoff, ponding depth/trench depth and infiltrating surface area been calculated using recommended design equations (see sizing methodology section/worksheet)?
- Is the bottom of the infiltration bed native soil, over-excavated to at least one foot in depth and replaced uniformly (with 2-4 inches of coarse sand amendments) without compaction?
- Has all vertical piping been classified correctly (see drainage section in manual)?
- Has an observation well been incorporated into the design to ensure that the 72 hour maximum drawdown time is met?
- Has an overflow route been provided to safely convey flows that overtop the facility or in the case that the facility becomes clogged?
- Has the overflow channel been designed to safely convey flows from peak design storm to a downstream conveyance system or acceptable discharge point?
- Has the infiltration trench been kept free of vegetation, and is all existing vegetation surrounding the trench been planted away from trench to avoid drip lines overhanging the facility?
- Is there safe maintenance access provided to the site for both wet and dry conditions?
- Has an access road along the length of the trench been provided if there is no existing road or parking lot that can be used for maintenance access?
- Has access to “operate a backhoe at ‘arms length’” been provided?
- Was the entire area draining to the facility stabilized before construction began?
- Have you ensured that the infiltration trench is not hydraulically connected to the storm water conveyance system?

- If heavy construction material was used to compact subgrade (not recommended), has the infiltrative capacity of the soil been restored via tilling or aerating prior to placing the infiltration bed?

- Were the exposed subgrade soils inspected by a civil engineer prior to construction to confirm suitable soil conditions for the infiltration facility?

INF-2 Drywell Checklist

- Has the drywell been located away from steep slopes (>25%)?
- Is the drywell set back from structures and leach fields?
- Is there at least 10 feet or vertical separation between the bottom of the drywell and the shallow groundwater table?
- Is the depth to bedrock adequate to provide proper infiltration?
- Has the site been checked to ensure that no preexisting contamination is present?
- Does the site have low sediment loading rates to prevent drywell from clogging?
- Has pretreatment been provided for all non-rooftop runoff flowing to the drywell?
- Has a geotechnical investigation and report been provided to ensure site meets specifications for an infiltration facility (including soil infiltration rate, groundwater separation, and no steep slopes)?
- Has a soil assessment report been completed, which determines the suitability of the site for an drywell, recommends a design infiltration rate, identifies the high depth to groundwater table surface elevation, and examines how the stormwater runoff will move in the soil?
- Has the drywell been located at a site that does not receive run off from sites that store or use chemicals or hazardous waste outside?
- Has the drywell been set back from existing septic system drain fields and drinking water wells?
- Has pretreatment been provided to prevent sediment and other large particulates?
- Is the surface area of the drywell large enough to infiltrate the storage volume in 72 hours based on maximum allowable depth?
- Is the top layer of the media filter gravel/choking stone/geotextile fabric if flow is sheet flow and 12 inches of surface soil if flow enters through an underground pipe (pipe should be fitted with a screen)?
- Is middle layer of media filter 3-5 feet of washed 1.5 to 3 in. gravel with void space of 30 to 40%?
- Is bottom layer of media filter 6" of clean, washed sand?

APPENDIX G: DESIGN CRITERIA CHECKLISTS

- Have one or more observation wells been installed?
- Do observation wells consist of recommended slotted 4-6 inch diameter PVC well screen capped with lockable, above-ground lid?
- Has the drywell been sized to capture and infiltrate the SUSMP defined water quality design volume?
- Has the drywell been designed to infiltrate all runoff within 72 hours?
- Has a long term percolation rate of 10% of the measured percolation rate been used in design (due to occlusion and particulate accumulation)?
- Has the maximum depth of runoff, ponding depth/trench depth and infiltrating surface area been calculated using recommended design equations (see sizing methodology section/worksheet)?
- Is the bottom of the infiltration bed native soil, over-excavated to at least one foot in depth and replaced uniformly (with 2-4 inches of coarse sand amendments) without compaction?
- Has all vertical piping been classified correctly (see drainage section in manual)?
- Has an observation well been incorporated to ensure that the 72 hour maximum drawdown time is met?
- Has an overflow route been provided to safely convey flows that overtop the facility or in the case that the facility becomes clogged?
- Has the overflow channel been designed to safely convey flows from peak design storm to a downstream conveyance system or acceptable discharge point?
- Has the drywell been kept free of vegetation, and is all existing vegetation surrounding the trench been planted away from trench to avoid drip lines overhanging the facility?
- Is there safe maintenance access provided to the site for both wet and dry conditions?
- Has maintenance access been provided?
- Was the entire area draining to the facility stabilized before construction began?
- Have you ensured that the infiltration trench is not hydraulically connected to the storm water system?

- If heavy construction material was used to compact subgrade (not recommended), has the infiltrative capacity of the soil been restored via tilling or aerating prior to placing the infiltration bed?

- Were the exposed subgrade soils inspected by a civil engineer prior to construction to confirm suitable soil conditions for the infiltration facility?

INF-3 Proprietary Infiltration BMPs Checklist

- Has the infiltration facility been located away from steep slopes (>25%)?
- Is the infiltration facility set back from structures and leach fields?
- Is there at least 10 feet or vertical separation between the bottom of the infiltration facility and the shallow groundwater table?
- Is the depth to bedrock adequate to provide proper infiltration?
- Has the site been checked to ensure that no preexisting contamination is present?
- Does the site have low sediment loading rates to prevent infiltration facility clogging?
- Has pretreatment been provided to prevent premature failure (If infiltration facility fails, complete construction is required)?
- Has infiltration facility been designed to receive runoff only from sections of the site that have been stabilized?
- If infiltration facility fails, complete construction is required
- Has a geotechnical investigation and report been provided to ensure site meets specifications for an infiltration facility (including soil infiltration rate, groundwater separation, and no steep slopes)?
- Has a soil assessment report been completed, which determines the suitability of the site for an infiltration trench, recommends a design infiltration rate, identifies the high depth to groundwater table surface elevation, and examines how the stormwater runoff will move in the soil?
- Has the infiltration trench been located at a site that does not receive run off from sites that store or use chemicals or hazardous waste outside?
- Has the infiltration BMP been sized to capture and treat the water quality design volume?
- Has a long term percolation rate of 10% of the measured percolation rate been used in design (due to occlusion and particulate accumulation)?
- Have the recommended sizing guidelines set by the vendor been referenced and used for selection and use of infiltration facility?

INF-4 Permeable Pavement Checklist

- Has the permeable pavement been located away from steep slopes (>25%)?
- Is the permeable pavement set back from structures and leach fields?
- Is there at least 10 feet or vertical separation between the bottom of the permeable pavement and the shallow groundwater table?
- Is the depth to bedrock adequate to provide proper infiltration?
- Has the site been checked to ensure that no preexisting contamination is present?
- Does the site have low sediment loading rates to prevent infiltration trench clogging?
- Has the permeable pavement been designed to receive runoff only from sections of the site that have been stabilized?
- Has a geotechnical investigation and report been provided to ensure site meets specifications for an infiltration facility (including soil infiltration rate, groundwater separation, and no steep slopes)?
- Has a soil assessment report been completed, which determines the suitability of the site for an infiltration trench, recommends a design infiltration rate, identifies the high depth to groundwater table surface elevation, and examines how the stormwater runoff will move in the soil?
- Has the permeable pavement been located at a site that does not receive run off from sites that store or use chemicals or hazardous waste outside?
- Has the run off been assessed for necessity of pretreatment?
- If pretreatment is required, has it been provided to treat run on before it reaches permeable pavement?
- Has the infiltration BMP been sized to capture and treat the water quality design volume?
- Have the infiltration capabilities of the site been assessed (i.e. full, partial, or no infiltration allowed)?
- If no infiltration is allowed, has an underdrain been prohibited?

- If permeable pavement is located on a site with a slope greater than 2%, has the area been terraced to prevent lateral flow through subsurface?
- Has the permeable pavement been designed to infiltrate flows through four different layers (incl. top wearing layer, stone reservoir, and transition layers) of material (or through a similar system)?
- Has the depth of each layer (and void space), along with the hydrology, hydraulics, and structural requirements of the site been determined and approved by a licensed civil engineer?
- If proprietary permeable pavement is used (i.e. concrete or other pavers), have the design requirements and installation steps been obtained from the vendor and referenced in the selection and construction of the permeable pavement?
- Has the permeable pavement been designed to drain in less than 72 hours and allowed to dry out periodically?
- Has a long term percolation rate of 10% of the measured percolation rate been used in design (due to occlusion and particulate accumulation)?
- Has an overflow mechanism been included in the pavement design?
- If the overflow mechanism employed is perimeter control, have controls such as a perimeter vegetated swale, perimeter Bioretention, storm drain inlets, or other acceptable control been implemented?
- If the overflow mechanism employed are overflow pipes, have the pipes been connected to the underdrain, are they located away from vehicular traffic, and is the top of the pipe fitted with a screen?
- Has the pavement been laid close to level with bottom of base layers level to ensure uniform infiltration?
- Are site materials stored away from permeable pavement?
- Has landscaping and stabilization of adjacent areas been completed before installation of pavement?

GS-1 Hydrodynamic Separation Device Checklist

- Has the vendor been contacted for the latest model and design guidance prior to selection of device?
- Has the device been sized to capture and treat the water quality design flow rate?
- Has the vendor been contacted for sizing and installation guidance?
- Has periodic maintenance been scheduled and budgeted for?

GS-2 Catch Basin Insert Checklist

- Has the vendor been contacted for the latest model and design guidance prior to selection of device?
- Has the insert been sized to capture and treat the water quality design flow rate?
- Has the vendor been contacted for sizing and installation guidance?
- Has periodic maintenance been scheduled and budgeted for?

APPENDIX H: STORMWATER CONTROL MEASURE ACCESS AND MAINTENANCE AGREEMENTS

(Long Form)

Recorded at the request of:

City of _____

After recording, return to:

City of _____

City Clerk

Stormwater Treatment Device Access and Maintenance Agreement

OWNER:

PROPERTY ADDRESS: _____

APN:

THIS AGREEMENT is made and entered into in _____,
California, this ___ day of _____, by and between _____
_____, hereinafter referred to as "Owner" and the CITY OF _____
_____, a municipal corporation, located in the County of Ventura,
State of California hereinafter referred to as "CITY";

WHEREAS, the Owner owns real property ("Property") in the City of _____,
County of Ventura, State of California, more specifically described in Exhibit "A" and
depicted in Exhibit "B", each of which exhibits is attached hereto and incorporated
herein by this reference;

WHEREAS, at the time of initial approval of development project known as _____
_____ within the Property described
herein, the City required the project to employ on-site control measures to minimize
pollutants in urban runoff;

WHEREAS, the Owner has chosen to install a _____
_____, hereinafter
referred to as "Device", as the on-site control measure to minimize pollutants in
urban runoff;

WHEREAS, said Device has been installed in accordance with plans and
specifications accepted by the City;

WHEREAS, said Device, with installation on private property and draining only private property, is a private facility with all maintenance or replacement, therefore, the sole responsibility of the Owner in accordance with the terms of this Agreement;

WHEREAS, the Owner is aware that periodic and continuous maintenance, including, but not necessarily limited to, filter material replacement and sediment removal, is required to assure peak performance of Device and that, furthermore, such maintenance activity will require compliance with all Local, State, or Federal laws and regulations, including those pertaining to confined space and waste disposal methods, in effect at the time such maintenance occurs;

NOW THEREFORE, it is mutually stipulated and agreed as follows:

- 1) Owner hereby provides the City of City's designee complete access, of any duration, to the Device and its immediate vicinity at any time, upon reasonable notice, or in the event of emergency, as determined by City's Director of Public Works no advance notice, for the purpose of inspection, sampling, testing of the Device, and in case of emergency, to undertake all necessary repairs or other preventative measures at owner's expense as provided in paragraph 3 below. City shall make every effort at all times to minimize or avoid interference with Owner's use of the Property.
- 2) Owner shall use its best efforts diligently to maintain the Device in a manner assuring peak performance at all times. All reasonable precautions shall be exercised by Owner and Owner's representative or contractor in the removal and extraction of material(s) from the Device and the ultimate disposal of the material(s) in a manner consistent with all relevant laws and regulations in effect at the time. As may be requested from time to time by the City, the Owner shall provide the City with documentation identifying the material(s) removed, the quantity, and disposal destination.
- 3) In the event Owner, or its successors or assigns, fails to accomplish the necessary maintenance contemplated by this Agreement, within five (5) days of being given written notice by the City, the City is hereby authorized to cause any maintenance necessary to be done and charge the entire cost and expense to the Owner or Owner's successors or assigns, including administrative costs, attorneys fees and interest thereon at the maximum rate authorized by the Civil Code from the date of the notice of expense until paid in full.
- 4) The City may require the owner to post security in form and for a time period satisfactory to the city of guarantee of the performance of the obligations stated herein. Should the Owner fail to perform the obligations under the Agreement, the City may, in the case of a cash bond, act for the Owner using the proceeds from it, or in the case of a surety bond, require the sureties to perform the obligations of the Agreement. As an additional remedy, the Director may withdraw any previous stormwater related approval with respect to the

APPENDIX H: STORMWATER CONTROL MEASURES ACCESS AND MAINTENANCE AGREEMENTS

property on which a Device has been installed until such time as Owner repays to City it's reasonable costs incurred in accordance with paragraph 3 above.

- 5) This agreement shall be recorded in the Office of the Recorder of Ventura County, California, at the expense of the Owner and shall constitute notice to all successors and assigns of the title to said Property of the obligation herein set forth, and also a lien in such amount as will fully reimburse the City, including interest as herein above set forth, subject to foreclosure in event of default in payment.
- 6) In event of legal action occasioned by any default or action of the Owner, or its successors or assigns, then the Owner and its successors or assigns agree(s) to pay all costs incurred by the City in enforcing the terms of this Agreement, including reasonable attorney's fees and costs, and that the same shall become a part of the lien against said Property.
- 7) It is the intent of the parties hereto that burdens and benefits herein undertaken shall constitute covenants that run with said Property and constitute a lien there against.
- 8) The obligations herein undertaken shall be binding upon the heirs, successors, executors, administrators and assigns of the parties hereto. The term "Owner" shall include not only the present Owner, but also its heirs, successors, executors, administrators, and assigns. Owner shall notify any successor to title of all or part of the Property about the existence of this Agreement. Owner shall provide such notice prior to such successor obtaining an interest in all or part of the Property. Owner shall provide a copy of such notice to the City at the same time such notice is provided to the successor.
- 9) Time is of the essence in the performance of this Agreement.
- 10) Any notice to a party required or called for in this Agreement shall be served in person, or by deposit in the U.S. Mail, first class postage prepaid, to the address set forth below. Notice(s) shall be deemed effective upon receipt, or seventy-two (72) hours after deposit in the U.S. Mail, whichever is earlier. A party may change a notice address only by providing written notice thereof to the other party.

(Short Form)

Recorded at the request of and mail to:

Covenant and Agreement Regarding

Stormwater Treatment Device Maintenance

The undersigned hereby certify that we are the owners of hereinafter legally described real property located in the City of _____, County of Ventura, State of California.

Legal Description: _____

as recorded in Book _____, Page _____, Records of Ventura County,

which property is located and known as **(Address):** _____

And in consideration of the City of _____ allowing _____

on said property, we do hereby covenant and agree to and with said City to maintain according to the Maintenance Plan (Attachment 1), all structural stormwater treatment devices including the following:

This Covenant and Agreement shall run all of the above described land and shall be binding upon ourselves, and future owners, encumbrances, their successors, heirs, or assignees and shall continue in effect until released by the authority of the City upon submittal of request, applicable fees, and evidence that this Covenant and Agreement is no longer required by law.

NOTARIES ON FOLLOWING PAGE

APPENDIX I : STORMWATER CONTROL MEASURE MAINTENANCE PLAN GUIDELINES AND CHECKLISTS

Included in this appendix are a series of checklists that can be used by both inspectors and maintenance personnel to ensure that observed deficiencies in BMPs are maintained appropriately. The BMP Inspection/Maintenance Checklists are presented in the following order:

- 1) [Bioretention/Planter Box](#)
- 25) [Vegetated Swale Filter](#)
- 26) [Vegetated Filter Strip](#)
- 27) [Sand Filter](#)
- 28) [Infiltration BMPs](#)
- 29) [Permeable Pavement](#)
- 30) [Constructed Treatment Wetland](#)
- 31) [Wet Retention Basin](#)
- 32) [Dry Extended Detention Basin](#)
- 33) [Proprietary Devices](#)

I.1 Bioretention/Planter Box Inspection and Maintenance Checklist

Date: _____ Work Order # _____

Type of Inspection: post-storm annual routine post-wet season pre-wet season

Facility: _____ Inspector(s): _____

Defect	Conditions When Maintenance Is Needed	Inspection Result (0, 1, or 2) [†]	Date Maintenance Performed	Comments or Action(s) Taken to Resolve Issue
Appearance	Untidy			
Trash and Debris Accumulation	Trash, plant litter and dead leaves accumulated on surface.			
Vegetation	Unhealthy plants and appearance.			
Irrigation	Functioning incorrectly (if applicable).			
Inlet	Inlet pipe blocked or impeded.			
Splash Blocks	Blocks or pads correctly positioned to prevent erosion.			
Overflow	Overflow pipe blocked or broken.			
Filter media	Infiltration design rate is met (e.g., drains 36-48 hours after moderate - large storm event).			

[†]Maintenance: Enter 0 if satisfactory, 1 if maintenance is needed and include WO#. Enter 2 if maintenance was performed same day.

I.2 Vegetated Swale Filter Inspection and Maintenance Checklist

Date: _____ Work Order # _____

Type of Inspection: post-storm annual routine post-wet season pre-wet season

Facility: _____ Inspector(s): _____

Defect	Conditions When Maintenance Is Needed	Inspection Result (0, 1, or 2)†	Date Maintenance Performed	Comments or Action(s) Taken to Resolve Issue
Appearance	Untidy			
Trash and Debris Accumulation	Trash and debris accumulated in the swale.			
Vegetation	When the grass becomes excessively tall (greater than 10-inches); when nuisance weeds and other vegetation start to take over.			
Excessive Shading	Vegetation growth is poor because sunlight does not reach swale. Evaluate vegetation suitability.			
Poor Vegetation Coverage	When vegetation is sparse or bare or eroded patches occur in more than 10% of the swale bottom. Evaluate vegetation suitability.			
Sediment Accumulation	Sediment depth exceeds 2 inches or covers more than 10% of design area.			
Standing Water	When water stands in the swale between storms and does not drain freely.			
Flow spreader or Check Dams	Flow spreader or check dams uneven or clogged so that flows are not uniformly distributed through entire swale width.			

APPENDIX I: STORMWATER BMP MAINTENANCE PLAN GUIDANCE AND CHECKLISTS

Defect	Conditions When Maintenance Is Needed	Inspection Result (0, 1, or 2)†	Date Maintenance Performed	Comments or Action(s) Taken to Resolve Issue
Constant Baseflow	When small quantities of water continually flow through the swale, even when it has been dry for weeks and an eroded, muddy channel has formed in the swale bottom.			
Inlet/Outlet	Inlet/outlet areas clogged with sediment and/or debris.			
Erosion/ Scouring	Eroded or scoured swale bottom due to flow channelization, or higher flows. Eroded or rilled side slopes.			
	Eroded or undercut inlet/outlet structures			

†Maintenance: Enter 0 if satisfactory, 1 if maintenance is needed and include WO#. Enter 2 if maintenance was performed same day.

I.3 Vegetated Filter Strip Inspection and Maintenance Checklist

Date: _____ Work Order # _____

Type of Inspection: post-storm annual routine post-wet season pre-wet season

Facility: _____ Inspector(s): _____

Defect	Conditions When Maintenance Is Needed	Inspection Result (0, 1 or 2) [†]	Date Maintenance Performed	Comments or Action(s) Taken to Resolve Issue
Appearance	Untidy			
Trash and Debris Accumulation	Trash and debris accumulated on the filter strip.			
Vegetation	When the grass becomes excessively tall (greater than 10-inches); when nuisance weeds and other vegetation starts to take over.			
Excessive Shading	Grass growth is poor because sunlight does not reach swale. Evaluate grass species suitability.			
Poor Vegetation Coverage	When grass is sparse or bare or eroded patches occur in more than 10% of the swale bottom. Evaluate grass species suitability.			
Erosion/Scouring	Eroded or scoured areas due to flow channelization, or higher flows.			
Sediment Accumulation on Grass	Sediment depth exceeds 2 inches.			
Flow spreader	Flow spreader uneven or clogged so that flows are not uniformly distributed through entire filter width.			

[†]Maintenance: Enter 0 if satisfactory, 1 if maintenance is needed and include WO#. Enter 2 if maintenance was performed same day.

I.4 Sand Filter Inspection and Maintenance Checklist

Date: _____ Work Order # _____

Type of Inspection: post-storm annual routine post-wet season pre-wet season

Facility: _____ Inspector(s): _____

Defect	Conditions When Maintenance Is Needed	Inspection Result (0,1, or 2) [†]	Date Maintenance Performed	Comments or Action(s) taken to resolve issue
Trash & Debris	Any trash and debris which exceed 5 cubic feet per 1,000 square feet of filter bed area (one standard garbage can). In general, there shall be no visual evidence of dumping. If less than threshold all trash and debris will be removed as part of next scheduled maintenance.			
Inlet erosion	Visible evident of erosion occurring near flow spreader outlets.			
Slow drain time	Standing water long after storm has passed (after 24 to 48 hours) and/or flow through the overflow pipes occurs frequently.			
Concentrated Flow	Flow spreader uneven or clogged so that flows are not uniformly distributed across the sand filter.			
Appearance of poisonous, noxious or nuisance vegetation	Excessive grass and weed growth. Noxious weeds, woody vegetation establishing, Turf growing over rock filter			
Standing Water	Standing water long after storm has passed (after 24 to 48 hours), and/or flow through the overflow pipes occurs frequently.			

APPENDIX I: STORMWATER BMP MAINTENANCE PLAN GUIDANCE AND CHECKLISTS

Defect	Conditions When Maintenance Is Needed	Inspection Result (0,1, or 2) [†]	Date Maintenance Performed	Comments or Action(s) taken to resolve issue
Tear in Filter Fabric	When there is a visible tear or rip in the filter fabric allowing water to bypass the fabric.			
Pipe Settlement	If piping has visibly settled more than 1 inch.			
Filter Media	Drawdown of water through the media takes longer than 1 hour and/or overflow occurs frequently.			
Short Circuiting	Flows do not properly enter filter cartridges.			

[†]Maintenance: Enter 0 if satisfactory, 1 if maintenance is needed and include WO#. Enter 2 if maintenance was performed same day.

I.5 Infiltration BMP Inspection and Maintenance Checklist

Date: _____ Work Order # _____

Type of Inspection: post-storm annual routine post-wet season pre-wet season

Facility: _____ Inspector(s): _____

Defect	Conditions When Maintenance Is Needed	Inspection Result (0,1, or 2) [†]	Date Maintenance Performed	Comments or Action(s) Taken to Resolve Issue
Appearance, vegetative health	Mowing and trimming vegetation is needed to prevent establishment of woody vegetation, and for aesthetic and vector reasons.			
Vegetation	Poisonous or nuisance vegetation or noxious weeds.			
	Excessive loss of turf or ground cover (if applicable).			
Trash & Debris	Trash and debris > 5 cf/1,000 sf (one standard size garbage can).			
Contaminants and Pollution	Any evidence of oil, gasoline, contaminants or other pollutants.			
Erosion	Undercut or eroded areas at inlet or outlet structures.			
Sediment and Debris	Accumulation of sediment, debris, and oil/grease on surface, inflow, outlet or overflow structures.			
Sediment and Debris	Accumulation of sediment and debris, in sediment forebay and pretreatment devices.			
Water drainage rate	Standing water, or by visual inspection of wells (if available), indicates design drain times are not being achieved (i.e., within 72 hours).			

APPENDIX I: STORMWATER BMP MAINTENANCE PLAN GUIDANCE AND CHECKLISTS

Defect	Conditions When Maintenance Is Needed	Inspection Result (0,1, or 2) †	Date Maintenance Performed	Comments or Action(s) Taken to Resolve Issue
Media clogging surface layer	Lift surface layer (and filter fabric if installed) and check for media clogging with sediment (function may be able to be restored by replacing surface aggregate/filter cloth).			
Media clogging	Lift surface layer (and filter fabric if installed) and check for media clogging with sediment (partial or complete clogging which may require full replacement).			

†Maintenance: Enter 0 if satisfactory, 1 if maintenance is needed and include WO#. Enter 2 if maintenance was performed same day.

I.6 Permeable Pavement Inspection and Maintenance Checklist

Date: _____ Work Order # _____

Type of Inspection: post-storm annual routine post-wet season pre-wet season

Facility: _____ Inspector(s): _____

Defect	Conditions When Maintenance Is Needed	Inspection Result (0,1, or 2) †	Date Maintenance Performed	Comments or Action(s) taken to resolve issue
Sediment Accumulation	Sediment is visible			
Missing gravel/sand fill	There are noticeable gaps in between pavers			
Weeds/mosses filling voids	Vegetation is growing in/on permeable pavement			
Trash and Debris Accumulation	Trash and debris accumulated on the permeable pavement.			
Dead or dying vegetation in adjacent landscaping	Vegetation is dead or dying leaving bare soil prone to erosion			
Surface clog	Clogging is evidenced by ponding on the surface			
Overflow clog	Excessive build up of water accompanied by observation of low flow in observation well (connected to underdrain system) If a surface overflow system is used, observation of an obvious clog			
Visual contaminants and pollution	Any visual evidence of oil, gasoline, contaminants or other pollutants.			
Erosion	Tributary area Exhibits signs of erosion Noticeably not completely stabilized			

APPENDIX I: STORMWATER BMP MAINTENANCE PLAN GUIDANCE AND CHECKLISTS

Defect	Conditions When Maintenance Is Needed	Inspection Result (0,1, or 2) [†]	Date Maintenance Performed	Comments or Action(s) taken to resolve issue
Deterioration/ Roughening	Integrity of pavement is compromised (i.e., cracks, depressions, crumbling, etc.)			
Subsurface Clog	Clogging is evidenced by ponding on the surface and is not remedied by addressing surface clogging.			
[†] Maintenance: Enter 0 if satisfactory, 1 if maintenance is needed and include WO#. Enter 2 if maintenance was performed same day.				

I.7 Constructed Treatment Wetland Inspection and Maintenance Checklist

Date: _____ Work Order # _____

Type of Inspection: post-storm annual routine post-wet season pre-wet season

Facility: _____ Inspector(s): _____

Defect	Conditions When Maintenance Is Needed	Inspection Result (0,1, or 2) [†]	Date Maintenance Performed	Comments or Action(s) taken to resolve issue
Trash & Debris	Any trash and debris which exceed 5 cubic feet per 1,000 sf of basin area (one standard garbage can). In general, there shall be no visual evidence of dumping. If less than threshold all trash and debris will be removed as part of next scheduled maintenance. If trash and debris is observed blocking or partially blocking an outlet structure or inhibiting flows between cells, it shall be removed quickly			
Sediment Accumulation	Sediment accumulation in basin bottom that exceeds the depth of sediment zone plus 6 inches in the sediment forebay. If sediment is blocking an inlet or outlet, it shall be removed.			
Erosion	Erosion of basin's side slopes and/or scouring of basin bottom.			
Oil Sheen on Water	Prevalent and visible oil sheen.			

APPENDIX I: STORMWATER BMP MAINTENANCE PLAN GUIDANCE AND CHECKLISTS

Defect	Conditions When Maintenance Is Needed	Inspection Result (0,1, or 2) [†]	Date Maintenance Performed	Comments or Action(s) taken to resolve issue
Noxious Pests	Visual observations or receipt of complaints of numbers of pests that would not be naturally occurring and could pose a threat to human or aquatic health.			
Water Level	First cell empty, doesn't hold water.			
Aesthetics	Minor vegetation removal and thinning. Mowing berms and surroundings			
Noxious Weeds	Any evidence of noxious weeds.			
Tree Growth	Tree growth does not allow maintenance access or interferes with maintenance activity (i.e., slope mowing, silt removal, vactoring, or equipment movements). If trees are not interfering, do not remove. Dead, diseased, or dying trees shall be removed.			
Settling of Berm	If settlement is apparent. Settling can be an indication of more severe problems with the berm or outlet works. A geotechnical engineer shall be consulted to determine the source of the settlement if the dike/berm is serving as a dam.			
Piping through Berm	Discernable water flow through basin berm. Ongoing erosion with potential for erosion to continue. A licensed geotechnical engineer shall be called in to inspect and evaluate condition and recommend repair of condition.			

APPENDIX I: STORMWATER BMP MAINTENANCE PLAN GUIDANCE AND CHECKLISTS

Defect	Conditions When Maintenance Is Needed	Inspection Result (0,1, or 2) [†]	Date Maintenance Performed	Comments or Action(s) taken to resolve issue
Tree and Large Shrub Growth on Downstream Slope of Embankments	Tree and large shrub growth on downstream slopes of embankments may prevent inspection and provide habitat for burrowing rodents.			
Erosion on Spillway	Rock is missing and soil is exposed at top of spillway or outside slope.			
Gate/Fence Damage	Damage to gate/fence, including missing locks and hinges			
[†] Maintenance: Enter 0 if satisfactory, 1 if maintenance is needed and include WO#. Enter 2 if maintenance was performed same day.				

I.8 Wet Retention Basin Inspection and Maintenance Checklist

Date: _____ Work Order # _____

Type of Inspection: post-storm annual routine post-wet season pre-wet season

Facility: _____ Inspector(s): _____

Defect	Conditions When Maintenance Is Needed	Inspection Result (0,1, or 2) [†]	Date Maintenance Performed	Comments or Action(s) taken to resolve issue
Trash & Debris	Any trash and debris which exceed 5 cubic feet per 1,000 sf of basin area (one standard garbage can) or if trash and debris is excessively clogging the outlet structure. If less than threshold all trash and debris will be removed as part of next scheduled maintenance.			
Sediment Accumulation	Sediment accumulation in basin bottom that exceeds the depth of the design sediment zone plus 6 inches, usually in the first cell.			
Erosion	Erosion of basin's side slopes and/or scouring of basin bottom.			
Oil Sheen on Water	Prevalent and visible oil sheen.			
Noxious Pests	Visual observations or receipt of complaints of numbers of pests that would not be naturally occurring and could pose a threat to human or aquatic health.			
Water Level	First cell empty, doesn't hold water.			
Algae Mats	Algae mats over more than 20% of the water surface.			
Aesthetics	Minor vegetation removal and thinning. Mowing berms and surroundings			

APPENDIX I: STORMWATER BMP MAINTENANCE PLAN GUIDANCE AND CHECKLISTS

Defect	Conditions When Maintenance Is Needed	Inspection Result (0,1, or 2) [†]	Date Maintenance Performed	Comments or Action(s) taken to resolve issue
Noxious Weeds	Any evidence of noxious weeds.			
Tree Growth	Tree growth does not allow maintenance access or interferes with maintenance activity (i.e., slope mowing, silt removal, vactoring, or equipment movements). If trees are not interfering, do not remove. Dead, diseased, or dying trees shall be removed.			
Settling of Berm	If settlement is apparent. Settling can be an indication of more severe problems with the berm or outlet works. A geotechnical engineer shall be consulted to determine the source of the settlement if the dike/berm is serving as a dam.			
Piping through Berm	Discernable water flow through basin berm. Ongoing erosion with potential for erosion to continue. A licensed geotechnical engineer shall be called in to inspect and evaluate condition and recommend repair of condition.			
Tree and Large Shrub Growth on Downstream Slope of Embankments	Tree and large shrub growth on downstream slopes of embankments may prevent inspection and provide habitat for burrowing rodents.			
Erosion on Spillway	Rock is missing and soil is exposed at top of spillway or outside slope.			
Gate/Fence Damage	Damage to gate/fence, including missing locks and hinges			

[†]Maintenance: Enter 0 if satisfactory, 1 if maintenance is needed and include WO#. Enter 2 if maintenance was performed same day.

I.9 Dry Extended Detention Basin Inspection and Maintenance Checklist

Date: _____ Work Order # _____

Type of Inspection: post-storm annual routine post-wet season pre-wet season

Facility: _____ Inspector(s): _____

Defect	Conditions When Maintenance Is Needed	Inspection Result (0, 1 or 2)†	Date Maintenance Performed	Comments or Action(s) Taken to Resolve Issue
General				
Appearance	Untidy, un-mown (if applicable)			
Vegetation	Access problems or hazards; dead or dying trees			
	Poisonous or nuisance vegetation or noxious weeds			
Insects	Insects such as wasps and hornets interfere with maintenance activities.			
Rodent Holes	Any evidence of rodent holes if facility is acting as a dam or berm, or any evidence of water piping through dam or berm via rodent holes			
Trash and Debris	Trash and debris > 5 cf/1,000 sf (one standard size garbage can).			
Pollutants	Any evidence of oil, gasoline, contaminants or other pollutants			
Inlet/Outlet Pipe	Inlet/Outlet pipe clogged with sediment and/or debris. Basin not draining.			
Erosion	Erosion of the basin's side slopes and/or scouring of the basin bottom that exceeds 2-inches, or where continued erosion is prevalent.			

APPENDIX I: STORMWATER BMP MAINTENANCE PLAN GUIDANCE AND CHECKLISTS

Defect	Conditions When Maintenance Is Needed	Inspection Result (0, 1 or 2)†	Date Maintenance Performed	Comments or Action(s) Taken to Resolve Issue
Piping	Evidence of or visible water flow through basin berm.			
Settlement of Basin Dike/Berm	Any part of these components that has settled 4-inches or lower than the design elevation, or inspector determines dike/berm is unsound.			
Overflow Spillway	Rock is missing and/or soil is exposed at top of spillway or outside slope.			
Sediment Accumulation in Basin Bottom	Sediment accumulations in basin bottom that exceeds the depth of sediment zone plus 6-inches.			
Tree or shrub growth	Trees > 4 ft in height with potential blockage of inlet, outlet or spillway; or potential future bank stability problems			
Debris Barriers (e.g., Trash Racks)				
Trash and Debris	Trash or debris that is plugging more than 20% of the openings in the barrier.			
Damaged/ Missing Bars	Bars are bent out of shape more than 3 inches.			
	Bars are missing or entire barrier missing.			
	Bars are loose and rust is causing 50% deterioration to any part of barrier.			
Inlet/Outlet Pipe	Debris barrier missing or not attached to pipe.			
Fencing				
Missing or broken parts	Any defect in the fence that permits easy entry to a facility.			

APPENDIX I: STORMWATER BMP MAINTENANCE PLAN GUIDANCE AND CHECKLISTS

Defect	Conditions When Maintenance Is Needed	Inspection Result (0, 1 or 2)†	Date Maintenance Performed	Comments or Action(s) Taken to Resolve Issue
Erosion	Erosion more than 4 inches high and 12-18 inches wide, creating an opening under the fence.			
Damaged Parts	Damage to gate/fence, posts out of plumb, or rails bent more than 6 inches.			
Deteriorating Paint or Protective Coating	Part or parts that have a rusting or scaling condition that has affected structural adequacy.			
Gates				
Damaged or missing member	Missing gate or locking devices, broken or missing hinges, out of plum more than 6 inches and more than 1 foot out of design alignment, or missing stretcher bar, stretcher bands, and ties.			

†Maintenance: Enter 0 if satisfactory, 1 if maintenance is needed and include WO#. Enter 2 if maintenance was performed same day.

I.10 Proprietary Device Inspection and Maintenance Checklist

Date: _____ Work Order # _____

Type of Inspection: post-storm annual routine post-wet season pre-wet season

Facility: _____ Inspector(s): _____

Defect	Conditions When Maintenance Is Needed	Inspection Result (0,1, or 2) †	Date Maintenance Performed	Comments or Action(s) taken to resolve issue
Refer to the manufacturer's instructions for maintenance/inspection requirements, below are generic guidelines to supplement manufacturer's recommendations.				
Underground Vault				
Sediment Accumulation on Media	Sediment depth exceeds 0.25-inches.			
Sediment Accumulation in Vault	Sediment depth exceeds 6-inches in first chamber.			
Trash/Debris Accumulation	Trash and debris accumulated on compost filter bed.			
Sediment in Drain Pipes or Cleanouts	When drain pipes, clean-outs, become full with sediment and/or debris.			
Damaged Pipes	Any part of the pipes that are crushed or damaged due to corrosion and/or settlement.			
Access Cover Damaged/Not Working	Cover cannot be opened; one person cannot open the cover using normal lifting pressure, corrosion/deformation of cover.			
Vault Structure Includes Cracks in Wall, Bottom, Damage to	Cracks wider than 1/2-inch or evidence of soil particles entering the structure through the cracks, or maintenance/inspection personnel determine that the vault is not structurally sound.			

APPENDIX I: STORMWATER BMP MAINTENANCE PLAN GUIDANCE AND CHECKLISTS

Defect	Conditions When Maintenance Is Needed	Inspection Result (0,1, or 2) †	Date Maintenance Performed	Comments or Action(s) taken to resolve issue
Frame and/or Top Slab	Cracks wider than 1/2-inch at the joint of any inlet/outlet pipe or evidence of soil particles entering through the cracks.			
Baffles	Baffles corroding, cracking warping, and/or showing signs of failure as determined by maintenance/inspection person.			
Access Ladder Damaged	Ladder is corroded or deteriorated, not functioning properly, not securely attached to structure wall, missing rungs, cracks, or misaligned.			
Below Ground Cartridge Type				
Filter Media	Drawdown of water through the media takes longer than 1 hour and/or overflow occurs frequently.			
Short Circuiting	Flows do not properly enter filter cartridges.			

†Maintenance: Enter 0 if satisfactory, 1 if maintenance is needed and include WO#. Enter 2 if maintenance was performed same day.

Executive Summary

This Annual Report discusses the Permittees' Permit compliance activities for the period of July 1, 2011 to June 30, 2012, the second year of the Permit. It includes a description of all activities conducted during the reporting period and the efforts made to improve water quality throughout Ventura County by the Permittees. The purpose of this report is to both show compliance with NPDES Permit No. CAS004002/Order No. 10-108 (Permit), and meet the reporting requirement which requires an Annual Stormwater Report submitted by December 15th of each year. Since the Permit did not require a Stormwater Management Plan this report also serves as a way to clarify the Permit's requirements and the effort necessary to meet them. Finally, program effectiveness assessment of the implementation of the permit requirements are examined with potential areas for improvement identified.

The cooperation and effort of the Ventura Countywide Permittees, who contributed the information and data regarding their various programs, was instrumental in the preparation of this report. The Permittees cooperate through the Program to ensure information and workloads are shared, economies of scale achieved and a better Countywide Stormwater Quality Management Program is created. The Permittees through implementation of various comprehensive program elements have strived for improved water quality through compliance with all requirements of the Permit.

Notable accomplishments made by the Permittees and the Program over this reporting period include:

- Began a comprehensive data analysis effort, aiming to identify historical trends in water quality and pollutants of concern to receiving waters.
- Implemented the first phase of a pyrethroid study that showed no significant sediment toxicity or concentrations approaching levels of pyrethroids known to be toxic;
- Initiated development of a long term strategic plan for addressing water quality issues in the County including identifying the goals and objectives that will ensure success when accomplished;
- Responded to elevated levels of pentachlorophenol at an urban outfall with a special investigation that conclusively found the source, and initiated a partnership in a multi-agency effort to eliminate the discharge.
- Implementation of a revised Technical Guidance Manual for new and significant re-development including providing an electronic application tool for projects to determine applicability and calculate retention volumes;
- In-school outreach rallies done at 26 schools to over 23,000 students with the cooperation of local radio station Q104.7;
- Participation in the statewide Coastal Cleanup Day Event at 24 different beaches and inland waterways;
- Offsite compliance program options for developments that prove technical infeasibilities to onsite LID;
- The Stormwater Monitoring Program was able to achieve a 91.8% success rate in meeting program data quality objectives;

- Continued program improvement through implementation of the recommendations of a detailed program efficiency audit of the Principal Permittee;
- Participation in Stormwater Monitoring Coalition of Southern California, Southern California Coastal Water Research Project (SCCWRP), and CASQA;
- Cooperation and commitment to SCCWRP to aid in a hydromodification effects study.

This year the Stormwater Monitoring Program modified its application of the California Toxics Rule (CTR) Numeric Criteria for Priority Toxic Pollutants to determine water quality exceedances in receiving waters. The driver for this change was the inconsistent application of acute and chronic criteria in the past. The new approach is more consistent with other stormwater agencies in southern California, and provides more consistent protection of beneficial uses.

The Stormwater Monitoring Program detected Aluminum, *E. coli*, and fecal coliforms at elevated levels at most sites during wet-weather events, but with the exception of *E. coli*, rarely during dry-weather events. Other constituents that were found at elevated levels during the 2011/12 monitoring season include chloride and total dissolved solids (predominantly during the dry-weather event); dissolved oxygen; dissolved copper; and pH (dry weather). Constituents that were seen at elevated levels at Major Outfalls only once during the season include total chromium, bis(2-ethylhexyl)phthalate, benzo(a)pyrene, and pentachlorophenol; and at Mass Emission stations only once during the year the metals (total) barium, cadmium, chromium, and nickel. In the Water Quality Monitoring Section of this year's report is an analysis of the historical mass emission data done to identify statistically significant trends. This analysis shows improvement in water quality identified through the Program's monitoring program, helps identify Pollutants of Concern, and will be used to direct the Program's efforts.

Continued in this Annual Report are the Performance Standards for specific Permit requirements identified in each section along with the Permittees' status on achieving that standard. Permit compliance cannot be directly inferred solely by these Performance Standards as the complete effort of the Permittees cannot be reflected through these discrete metrics. Rather, the information is more suitable for use by for the Permittees to gage their efforts and identify areas of needed improvement.

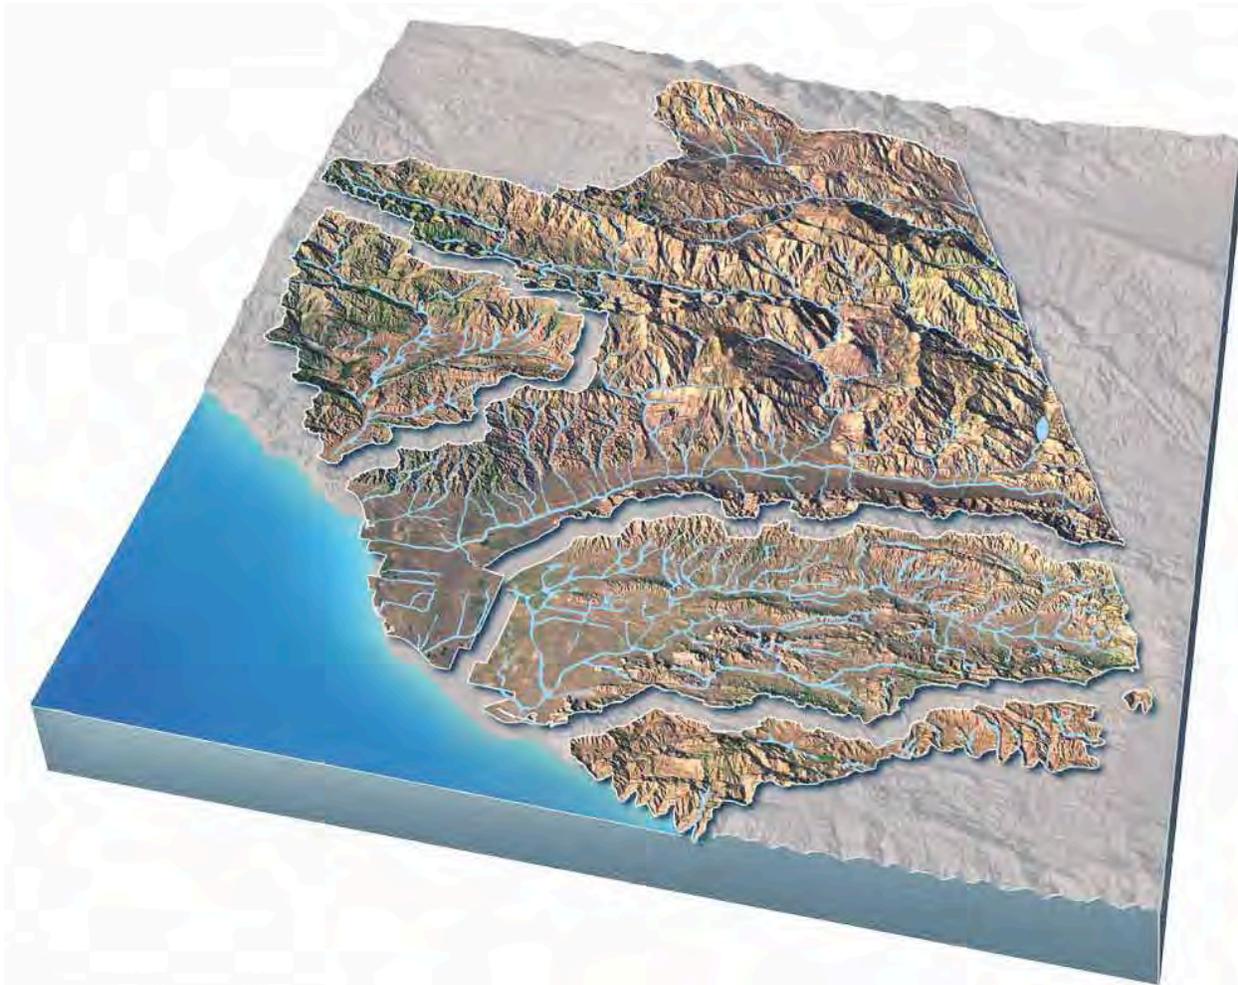

The Program has adopted a method for assessing program effectiveness based on California Stormwater Quality Association's (CASQA) six progressive outcome levels for the effectiveness assessment which range from documenting efforts to measurably protecting receiving water quality. Current program effectiveness measurements show the Program is continually effective in the first two outcome levels of documenting efforts and raising awareness. As implementation of the Program continues, improvements in the ability to measure the other outcome levels of changing behavior and reducing pollutant loads will be accurately measured and documented. The trends identified in the Water Quality Monitoring Section show real progress towards the Program's effectiveness at the ultimate goal - Outcome Level 6 protecting receiving water quality.

In summary, the Permittees continue aggressively moving forward to improve stormwater quality and eliminate dry weather flows. Each program element has a subcommittee working to develop needed forms, protocols, and procedures to ensure future permit compliance. The programs, methods and this report are continually being refined to improve effectiveness, apply lessons learned, identify and address additional sources of stormwater pollutants, and therefore water quality. Future program activities will include initiating an offsite compliance program for developments that prove technical infeasibilities and incorporating hydromodification control plans into the Technical Guidance Manual, increased analysis of the urban outfall monitoring data generated for each Permittee, and development of a long term strategic plan for addressing water quality issues in the County, including identifying the goals and objectives that will ensure success when accomplished.

1 Introduction

The Watershed Protection District (Principal Permittee), the County of Ventura, and the incorporated cities of Camarillo, Fillmore, Moorpark, Ojai, Oxnard, Port Hueneme, Ventura, Santa Paula, Simi Valley, and Thousand Oaks, (each a Permittee, and collectively known as Permittees) operate municipal storm drain systems and discharge stormwater and urban runoff pursuant to the countywide NPDES permit (Board Order No. 10-0108 or Permit). This Permit, administered by the Los Angeles Regional Water Quality Control Board (RWQCB), requires an Annual Stormwater Report and Assessment (Annual Report) be submitted by December 15th of each year.

The first stormwater permit for Ventura County was adopted in 1994 and included all ten cities, the County, and the Watershed Protection District. On July 27, 2000 a second permit was adopted that included logical and incremental increases in the requirements. That five-year permit was on administrative extension until May 7, 2009, when Board Order 09-0057 was adopted. Shortly after adoption of that permit the Regional Board rescinded it to hold a new adoption hearing. On July 8, 2010 Order No. R4 2010-0108 was adopted with minor changes. The 2010 Permit had a new set of implementation deadlines associated with it and replaced the order adopted in 2009 in its entirety.

***The Watersheds of Ventura County:
Ventura River, Santa Clara River, Calleguas Creek, and Malibu Creek***

1.1 PURPOSE AND ORGANIZATION OF REPORT

The primary purpose of this report is to document the Permittees' continued efforts to improve water quality and comply with the Permit. Since the Permit did not require a Stormwater Management Plan this report also serves as a way to clarify the Permit's requirements and the effort required to meet them. Finally, program effectiveness assessment of the implementation of the permit requirements are examined with potential areas for improvement identified.

The organization of the report reflects the organization of the Permit. Each section contains a description of the permit requirements and their purpose, the Permittee's program activities in that area with detailed descriptions of the efforts put forth in the 2011/12 permit year. The sections are as follows:

- **Program Management - Section 2.0** – Roles and responsibilities of the Permittees committee structure, and a program budget report for 2012/13.
- **Public Information and Public Participation Program – Section 3.0** - The efforts and effectiveness of pollution prevention education and outreach programs.
- **Industrial Commercial Business Program - Section 4.0** – The activities directed at effectively prohibiting non-stormwater discharges from businesses and industrial sites in order to reduce stormwater pollution to the maximum extent practicable.
- **Planning and Land Development Program - Section 5.0** – The minimization of the impact of new development and significant redevelopment on stormwater quality through use of Low Impact Development site design and water quality treatment BMPs.
- **Development Construction Program - Section 6.0** – Activities before and during construction through stormwater pollution prevention plans and inspections to ensure the protection of stormwater quality to the maximum extent practicable.
- **Public agencies Activities Program - Section 7.0** – Both the efforts to remove pollutants from MS4s, and to eliminate the adverse effects that municipal activities may have on water quality.
- **Illicit Discharge and Illegal Connections Elimination Program - Section 8.0** – Status of the tools, control measures and responses established to eliminate non-permit authorized discharges and connections to the storm drain system.
- **Water Quality Monitoring Program - Section 9.0** – A summary and analysis of the monitoring results from the Permit year. Includes a report describing efforts that are currently being implemented and additional BMPs that will be implemented to prevent or reduce any pollutants that are causing or contributing to the exceedance of Water Quality Objectives.

1.1.1 Major Program Accomplishments

Notable accomplishments that occurred during the reporting period include:

- Trends analysis of historic data mass emission data to success in reduction of pollutants of concern and identify potential emerging concerns;
- Pyrethroid study showing no significant toxicity or elevated levels of pyrethroids downstream of urban areas;
- Initiated development of a long term strategic plan for addressing water quality issues in the County including identifying the goals and objectives that will ensure success when accomplished;
- Response to elevated levels of pentachlorophenol at an urban outfall with a special investigation that conclusively found the source, and initiated a partnership in a multi-agency effort to eliminate the discharge;
- Implementation of a revised Technical Guidance Manual for new and significant re-development including providing an electronic application tool for projects to determine applicability and calculate retention volumes;
- In-school outreach rallies done at 26 schools to 23000 students with the cooperation of local radio station Q104.7;
- Participation in the statewide Coastal Cleanup Day Event at 24 different beaches and inland waterways;
- Offsite compliance program options for developments that prove technical infeasibilities to onsite LID;
- Continued program improvement through implementation of the recommendations of a detailed program efficiency audit of the Principal Permittee;
- Regional TMDL participation;
- Participation in the Stormwater Monitoring Coalition of Southern California, Southern California Coastal Water Research Project (SCCWRP), and CASQA;
- Cooperation and commitment to SCCWRP to aid in a hydromodification effects study;
- Integrated Regional Water Management Plan (IRWMP) Participation.

1.2 PROGRAM EFFECTIVENESS ASSESSMENT

The 2011/12 Annual Report documents the Program's comprehensive stormwater quality efforts that address a wide range of activities. Various Departments in each Permittee's agency cooperate in implementing the different elements or activities of the Program under their control. All of these efforts are examined for program effectiveness.

Each of the six Program Elements contains various Control Measures. Each Control Measure consists of a series of Performance Measures. Performance Measures are identified to document the progress of implementation and to measure the effectiveness of implemented BMPs.

The Program has adopted a method for assessing program effectiveness based on an approach developed by the California Stormwater Quality Association (CASQA). The effectiveness assessment is more comprehensive than assessments under past permits and addresses the major stormwater program areas and activities. The outcome levels represent ways in which the effectiveness of the program can be determined, even if it is intermediate¹.

Outcome levels help to categorize and describe the desired results of the Program Elements and related Control Measures. Pursuant to the 2007 CASQA guidance, outcomes for stormwater programs have been categorized into six levels, as shown in Figure 1-1. As illustrated, there are six outcome levels for the effectiveness assessment. The outcome levels help to categorize and describe the desired results or goals of the program.

Figure 1-1 Effectiveness Assessment Outcome Levels

Implementation Assessment	Target Audience & Source Assessment			Urban Runoff & Receiving Water Assessment	
	Outcome Level 2	Outcome Level 3	Outcome Level 4	Outcome Level 5	Outcome Level 6

4. Integrated Assessment					

Within each individual program section (starting with Chapter 3), the effectiveness assessment identifies the outcome level(s) achieved, as well as any program modifications that have been identified because of the assessment. The assessment section is at the end of each chapter.

Some important points to remember about these effectiveness assessments include:

¹ California Stormwater Quality Association, *Municipal Program Effectiveness Assessment Guidance*, May 2007.

- The ability of a stormwater program to assess an outcome level tends to become progressively more difficult as you assess higher outcome levels (levels 4-6). This is because the higher outcome levels assess the impact that the Permittees have on water quality, which requires a much more robust dataset over an extended period of time.
- Outcome levels 1-3 (and sometimes 4) are typically assessed using program management data, whereas outcome levels 4-6 are assessed using physical and/or water quality monitoring data.
- Each program element may be assessed at one or more outcome levels based on the data and information available.

Through the annual reports the effectiveness assessment will be expanded and modified as necessary in order to report out on key items.

To assess our ultimate effectiveness of improvement in receiving water conditions, the Program started a comprehensive data analysis effort, aiming to identify historical trends in water quality, priority pollutants and their sources to receiving waters. As part of this year's report in Section 9 Water Quality Monitoring, the trend analysis methods and results are presented.

The findings of the Mass Emission trend analysis reveals since 2001 twenty-six constituents, including metals, bacteria, nutrients, salts and one pesticide, have shown decreased concentrations at one or more stations. Only five constituents exhibited increasing trends, each time at only one of the stations. None of these constituents with increasing trends are causing water quality exceedances based on Basin Plan and CTR numeric water quality criteria. There has been a decreased in the average number of dry weather exceedances since 2001 at ME-SCR and ME-VR/VR2. The number of wet event exceedances has also decreased since 2004 at ME-CC and ME-VR, however this could be mostly explained by the smaller storm sizes and therefore fewer exceedances for metals in recent years.

These decreasing trends are good news for the environment and the Program, but still leave some questions. By following up to identify what causal agents are behind the trends then success can be repeated, problems avoided and a truly effective stormwater program created.

**Outcome Level 6 has
already been observed in
receiving waters.**

**Concentrations of nine
metals, E. coli, nutrients,
salts, and one pesticide
have significantly
trended downward since
2001.**

2 Program Management

2.1 PROGRAM IMPLEMENTATION

2.1.1 Mission Statement

To improve the focus and guide the actions of the program a mission statement was adopted by the Management Committee. Its purpose is to identify the overall goal, provide a sense of direction, and guide decision-making. It provides the framework or context within which the Program's strategies are guided. The Program's mission statement is below:

The Ventura Countywide Stormwater Quality Management Program, established in 1992 between the ten Cities, the County and District, works cooperatively on a regional basis to ensure compliance with the countywide Stormwater Permit through the development and implementation of an integrated, effective and fiscally responsible stormwater quality management program with the objective of protecting, maintaining and improving water quality in Ventura County for the common benefit of its residents and the environment.

2.1.2 Program Implementation

In 1992 the concept of a single countywide NPDES MS4 Stormwater Permit (Permit) was implemented in Ventura County. This began with the initial Report of Waste Discharge and the authorization to use the Watershed Protection District's Benefit Assessment to finance the activities and program efforts. Subsequently, on June 30, 1992, the District (as the Permit's Principal Permittee) entered into four separate District-zone-based implementation agreements with the ten Ventura County cities and the unincorporated areas of the county (the Permittees). Collectively, these four agreements are known as the Implementation Agreement for the Ventura Countywide Stormwater Quality Management Program. The Implementation Agreement identified the responsibilities of the Permittees and set forth the methodology for using the District's Benefit Assessment financing to fund the NPDES Stormwater Programs.

With the adoption of the second NPDES Permit, the Principal Permittee Program activities, responsibilities, and associated costs increased significantly. The District could no longer solely shoulder these fiscal obligations without assistance from the Permittees. In response, the Permittees' Public Works Directors created a committee to research the historical documentation from the District's Benefit Assessment Reports and draft a new implementation agreement.

In FY 2007/08, the first amendment to the agreement was approved to address this needed cost-sharing by amending the original agreement. In FY 2008/09 and 2009/10, the second and third amendments to the original agreement were approved to continue this needed cost-sharing.

The additional program costs for the Principal Permittee and Permittees associated with the 2010 NPDES Permit prompted further effort among the Public Works Directors to equitably share the increased costs. The result of that effort was a new NPDES Implementation Agreement to supersede the original agreement and amendments.

The Implementation Agreement defines the fiscal responsibilities (expenditures and contributions) of all collective parties with respect to the current Permit. It formalizes the Permittees' commitment to cooperate and to mutually fund an integrated Program for protecting and improving water quality in Ventura County.

2.2 PERMITTEE RESPONSIBILITIES

The responsibilities of the Principal Permittee and Permittees are defined within the Permit and the Implementation Agreement. These roles and responsibilities are outlined below.

2.2.1 Permittees

Each Permittee is responsible for implementing the NPDES Stormwater Program and Permit compliance within their jurisdiction. The main responsibility of each Permittee can be identified as follows:

- Comply with the requirements of the Permit through implementation within its jurisdiction of the various stormwater management programs outlined in the Permit;
- Coordinate among its internal departments and agencies, as necessary, to facilitate the implementation of the requirements of this Permit applicable to such Permittees in an efficient and cost-effective manner;
- Participate in intra-agency coordination (e.g., Planning Department, Fire Department, Building and Safety, Code Enforcement, Public Health, Parks and Recreation, and others) necessary to effectively implement the provisions of the Permit;
- Prepare and submit all reports or requests of information to the Principal Permittee in a timely fashion;
- Review, provide comments, and approve Program budgets, plans, strategies, management programs, and monitoring programs developed by the Principal Permittee or any subcommittee;
- Establish and maintain adequate legal authority;
- Apply appropriate enforcement actions as necessary within its jurisdictions to ensure compliance with applicable ordinances;
- Respond to, or arrange for, response to emergency situations, such as accidental spills, leaks, illicit discharges/illegal connections, etc., to prevent or reduce the discharge of pollutants to the storm drain systems and waters of the U.S. within its jurisdiction
- Conduct inspections of, and perform maintenance on, municipal infrastructure within its jurisdiction;
- Conduct and coordinate any surveys and source identification studies necessary to identify pollutant sources and drainage areas; and
- Participate in the Management Committee.

2.2.2 Principal Permittee

The role of the Principal Permittee is similar to the other Permittees with the addition of certain overall programmatic and facilitation responsibilities. These responsibilities do not include ensuring the compliance of the Permittees, as the Principal Permittee has no regulatory authority over the Permittees. The responsibilities outlined in the Permit include the following:

- Coordinate and facilitate activities necessary to comply with the requirements of the Permit;
- Act as liaison between the Permittees and the Regional Water Board on permitting issues;
- Provide for countywide consistency and program coordination;
- Provide technical and administrative support for subcommittees organized to implement this Order and its requirements;

- Convene the Committee Meetings constituted pursuant to Permit, upon designation of representatives;
- Implement a Public Information and Participation Program (PIPP) including developing a strategy to educate ethnic communities through culturally effective methods, and a plan to provide outreach in lieu of the school curriculum;
- Implement the monitoring program required in Attachment F of the Permit;
- Participate in the County Environmental Crimes Task Force;
- Provide resources for the collection, processing and submittal to the Regional Water Board of monitoring and annual reports, and summaries of other reports required under this Order. Establish uniform data submittal format and develop an Electronic Reporting Program;
- Participate in water quality meetings for watershed management and planning;
- Participate in the Southern California Storm Water Monitoring Coalition (SMC) Southern California Regional Bioassessment Monitoring Program
- Compile and make available on the internet a list of the general public reporting contacts; and
- Convene all Management Committee meetings.

In addition to responsibilities identified in the Permit, the Principal Permittee also performs the following for the benefit of the Program:

- Prepare communications, regulatory reports and submissions to the Regional Board;
- Provide Regional Representation for the Program and communicate information to the Permittees;
- Arrange for public access and review of Program plans and documents;
- Secure services of consultants as necessary;
- Implement activities of common interest to the Program;
- Develop/prepare/generate all materials and data common to all Permittees; and
- Update Permittees on RWQCB and US Environmental Protection Agency (USEPA) regulations.

2.3 MANAGEMENT ACTIVITIES

2.3.1 Management Committee

The NPDES Management Committee is the principal forum for directing the Program's development and implementation. This Committee is attended by senior staff from all Permittee agencies and meets monthly to assure Program continuity. Committee members have been authorized by their Director of Public Works as Management Committee Voting Representatives with the authority to approve Principal Permittee's budget and/or modifications. If no Representative is authorized, it is the Directors of Public Works responsibility to voice their opinion at meetings when these items are on the agenda. In addition to budgeting and program direction, this committee also periodically evaluates the need to create ad hoc committees or workgroups to develop tools and accomplish the objectives of the NPDES Stormwater Program. Although it is no longer

mandated that Permittees attend the meetings, participation in the Management Committee as necessary is a specific requirement of the Permit.

Performance Standard 2-1

<i>Participate in intra-agency coordination including Committee and Subcommittee Meetings to facilitate the implementation of the Permit</i>			
	<i>Yes</i>	<i>No</i>	<i>N/A</i>
<i>Camarillo</i>	<input checked="" type="checkbox"/>		
<i>Ventura County</i>	<input checked="" type="checkbox"/>		
<i>Fillmore</i>	<input checked="" type="checkbox"/>		
<i>Moorpark</i>	<input checked="" type="checkbox"/>		
<i>Ojai</i>	<input checked="" type="checkbox"/>		
<i>Oxnard</i>	<input checked="" type="checkbox"/>		
<i>Port Hueneme</i>	<input checked="" type="checkbox"/>		
<i>Ventura</i>	<input checked="" type="checkbox"/>		
<i>Santa Paula</i>	<input checked="" type="checkbox"/>		
<i>Simi Valley</i>	<input checked="" type="checkbox"/>		
<i>Thousand Oaks</i>	<input checked="" type="checkbox"/>		
<i>Watershed Protection</i>	<input checked="" type="checkbox"/>		

Subcommittees

The Subcommittees provide a forum for discussion of particular program elements and are attended by the staff with the appropriate expertise from each Permittee. These meetings allow for a more uniform approach and regional consistency to program management countywide. This helps provide a level playing field for businesses and residents countywide. More importantly it allows the Permittees to learn from each other and have access to tools that have already been developed. This is very beneficial for the smaller agencies which do not have at their disposal the resources available to the true Phase 1 cities (population over 100,000).

The subcommittees were created at the beginning of the program and have continued to meet and have evolved over the years as requirements and pollutant sources have changed. Subcommittee activities over this Permit Year have been devoted to identifying new Permit requirements and developing programs for compliance. Each subcommittee focuses on specific permit requirements and implementation programs. These generally follow the program sections of the permit, but the subcommittees also incorporate the whole permit in their analysis and integrated program development. The subcommittees and their program responsibilities are listed below. This list does not include any ad hoc, special project, or working groups that may have been formed by the Management Committee or from a logical outgrowth of the subcommittees. One such working group is the Capital Improvement Projects (CIP) Working Group set up to assist Permittees own capital improvement program engineers and staff to understand and implement the new post-construction requirements as well as the new General Construction Permit requirements in our public projects.

Residential/Public Outreach Subcommittee

The Principal Permittee’s countywide outreach program is guided by this subcommittee. Using information on pollutants identified through the monitoring program and 303(d) lists, this committee selects specific Pollutants of Concern to target each year and decides on the best methods of outreach and public education to influence a change in behavior, and regional message consistency.

Business and Illicit Discharge Control Subcommittee

Oversees the development of the model industrial/commercial and illicit discharge/illegal connections programs. Countywide consistency is created by developing inspection forms and sharing techniques and methods of identifying and educating businesses and industries targeted for inspections. Outreach materials focused on specific industries and businesses are also developed for countywide use by all Permittees. Illicit discharge identification and responses are included at every meeting and discussed. Enforcement experiences are shared to further the education of inspectors countywide.

Planning and Land Development Subcommittee

Planners and development engineers work together to provide regional tools for design, review, and conditioning of new development and redevelopment projects, and to promote regional consistency in

their application. Guidance and training are developed for the development community for the implementation of stormwater management control measures countywide. The guidelines developed are intended to improve water quality and mitigate potential water quality impacts from new development and significant redevelopment.

Construction Subcommittee

Regional consistency for inspections and enforcement are provided by developing model inspection checklists and identifying solutions to common problems. Information on the State General Construction Permit issues, training requirements and opportunities are shared and disseminated to the construction community.

Public Infrastructure

This subcommittee assists municipalities in the protection of their storm drain infrastructure from pollutants through best management practices and the development of model municipal activities programs, corporate yard inspections, and integrated pesticide management programs. It also works to identify solutions to infrastructure mapping and other permit requirements.

The Permit requires Permittee participation in the subcommittees as necessary. The Permittees have been very involved in subcommittees this permit year, including stepping up to the chair position on four of the five subcommittees. The value of the subcommittees to improve staff knowledge and abilities, achieve economies of scale, and provide regional program consistency is understood by all members. It is recognized that increased effort in the subcommittees will be rewarded by improvement in staff, resources, and the overall program.

2.3.2 Other Regional Committees/Work Groups

Many of the Permittees additionally participate in various watershed management advisory groups. These groups include: the Ventura County Integrated Resources Water Management Plan (IRWMP), Ventura River Watershed Planning Committee, Santa Clara River Watershed Committee, Wetlands Recovery Project, Calleguas Creek Watershed Management Committee, Matilija Dam Ecosystem Restoration Study, Channel Islands Beach Park Action Plan for Improving Water Quality, Malibu Creek Watershed Management Committee and Technical Advisory Committee, Steelhead Restoration and Recovery Plan, Beach Erosion Authority for Clean Oceans and Nourishment (BEACON), Southern California Coastal Water Research Project (SCCWRP), Stormwater Monitoring Coalition of Southern California (SMC), and the Ormond Beach Task Force. These watershed and regional groups focus their activities and discussions on specific concerns such as water quality, habitat restoration and flood control, as well as short, medium, and long-term solutions to improve water quality.

2.3.3 Management Framework – Program Implementation

Program development occurs through the Permittee, Countywide Program, and watershed management frameworks. At a jurisdictional level the Permittees have formally identified which departments and staff have responsibility for implementation of each program element within their jurisdictions. It may be necessary for the responsibility to be formally documented through Memorandums of Understanding or other tools. Smaller agencies tend not to require such formal agreements between departments, and in some cases there may be only a few people who are involved in the implementation of all aspects of the stormwater program.

2.3.4 Legal Authority

Although adequate legal authority existed for most pollutant discharges at the inception of the stormwater program in 1994, the Permittees determined that a Model Stormwater Quality Ordinance should be developed

to provide a more uniform countywide approach and to provide a legal underpinning to the entire Ventura Countywide NPDES Stormwater Program.

Performance Standard 2-2

<i>Ensure that its Stormwater Quality and LID Ordinances authorize enforcement of all requirements of the Permit? (by July 8, 2012)</i>			
	<i>Yes</i>	<i>No</i>	<i>In Progress</i>
<i>Camarillo</i>	<input checked="" type="checkbox"/>		
<i>Ventura County</i>	<input checked="" type="checkbox"/>		
<i>Fillmore</i>			<input checked="" type="checkbox"/>
<i>Moorpark</i>	<input checked="" type="checkbox"/>		
<i>Ojai</i>	<input checked="" type="checkbox"/>		
<i>Oxnard</i>	<input checked="" type="checkbox"/>		
<i>Port Hueneme</i>	<input checked="" type="checkbox"/>		
<i>Ventura</i>	<input checked="" type="checkbox"/>		
<i>Santa Paula</i>	<input checked="" type="checkbox"/>		
<i>Simi Valley</i>	<input checked="" type="checkbox"/>		
<i>Thousand Oaks</i>	<input checked="" type="checkbox"/>		
<i>Watershed Protection</i>			<input checked="" type="checkbox"/>

Subsequently, all of the Permittees adopted largely similar versions of the initial Model Stormwater Quality Ordinance. With the adoption of the Order No. 10-0108 the municipal ordinances must be updated by July 8, 2012, outside of this reporting period. The Permittees, led by the City of Moorpark, have already begun the process of drafting a model ordinance which can serve as the basis for each Permittee to adopt and authorize them to enforce all requirements of the Permit. Preliminary review by Counsel for the Permittees have determined the existing ordinances are capable of enforcing the Permit, however will be made stronger through the adopting of an improved ordinance.

Enforcement of the current ordinance and the detection, investigation and elimination of discharges undertaken by the Permittees during 2011/12 are described further in Section 8 Illicit connections and Illicit Discharge Elimination. In addition to prohibiting un-permitted discharges, the Stormwater Quality Ordinance, in conjunction with the conditions of land development, provides for requiring BMPs on new development and significant redevelopment. Stormwater quality ordinances have been adopted in each Permittees' jurisdictions as indicated in

Table 2-1 Ordinance Adoption Dates. As stated above, the requirement to update these ordinances to be able to enforce the new permit is required by July 8, 2012, outside of this reporting period.

Table 2-1 Ordinance Adoption Dates

Ordinance Adoption Dates		
Co-permittee	Adopted Date	Amendment Date
Camarillo	3/11/1998	In Progress
County of Ventura	10/2/2001	7/17/2012

Simi Valley	7/2/2012	
Thousand Oaks	10/14/1999	

2.3.5 **Watershed Protection District Stormwater Program Representation**

To stay informed of new science and regulations and gain economies of scale through regional efforts the Principal Permittee represents the Permittees by participating in the following organizations and associations:

California Association for Stormwater Agencies (CASQA)

The California Association of Stormwater Quality Agencies originally formed as an advisory body to the State Water Resources Control Board (SWRCB) on stormwater quality program issues is now a 501 (c)(3) non-profit organization. CASQA membership is composed of a diverse range of stormwater quality management organizations and individuals, including cities, counties, special districts, industries, and consulting firms throughout the state. A large part of its mission is to assist stormwater quality programs in California to learn collectively from the individual experiences of its members, learn from their mistakes, and provide awareness of regional and state issues. Since its inception in 1989, CASQA has evolved into the leading organization in California dealing with stormwater quality issues.

Southern California Coastal Water Research Project (SCCWRP)

The Southern California Coastal Water Research Project (SCCWRP) is a joint powers agency formed by fourteen agencies through a unique partnership between municipalities that discharge treated wastewater to the ocean, stormwater agencies, and regulators that oversee dischargers. Members work together to develop a solid scientific foundation for coastal environment management in southern California. SCCWRP's mission is to gather the necessary scientific information so that member agencies can effectively and cost-efficiently protect the Southern California coastal and marine environment. In addition, SCCWRP's mission is to ensure that the data it collects and synthesizes effectively reaches decision-makers, scientists, and the public.

Stormwater Monitoring Coalition of Southern California (SMC)

The SMC participants are the Ventura County Watershed Protection District, the County of Orange, the County of San Diego, the Los Angeles County Flood Control District, the San Bernardino County Flood Control District, the Riverside County Flood Control and Water Conservation District, the City of Long Beach, the City of Los Angeles, the Regional Water Quality Control Boards of Los Angeles Region, Santa Ana Region, and San Diego Region, the Southern California Coastal Water Research Project (SCCWRP), and the California Department of Transportation. They have decided to work together in a cooperative effort to develop scientific and technical tools needed in southern California to improve stormwater program implementation, assessment, and monitoring.

California Coalition for Clean Water (CCCW)

The California Coalition for Clean Water (CCCW) is an alliance of local governments and public agencies, labor, agriculture, business, housing, and development interests working together towards the development and implementation of water quality standards that protect water quality while balancing economic and social needs of local communities and the state. CCCW's mission is to assist the California Regional Water Quality Control Boards and SWRCB to adopt and implement sound water quality standards that reflect the intent and spirit of state and federal clean water laws.

National and Global Organizations

As Principal Permittee, the Watershed Protection District (District) participated jointly with SCCWRP and various other federal and international organizations such as the Society of Environmental Toxicology and Chemistry (SETAC). SETAC is a nonprofit, worldwide professional society comprised of individuals and institutions engaged in the study, analysis, and solution of environmental problems. SETAC's mission is to support the development of principles and practices for protection, enhancement, and management of sustainable environmental quality and ecosystem integrity.

SETAC promotes the advancement and application of scientific research related to contaminants and other stressors in the environment, education in the environmental sciences, and the use of science in environmental policy and decision-making.

2.4 FISCAL ANALYSIS

The Permittees have committed significant resources to permit compliance, reducing stormwater pollution, and improving the water quality in Ventura County. This Section presents a summary of the costs anticipated for the coming permit year by the Permittees in developing, implementing, and maintaining programs in order to comply with permit requirements. Also included is information on the different funding sources used by the Permittees to ensure that resources are available for permit compliance. Since each permittee shares in the cost of the Principal program the total cost shown for each Permittee is the sum of those *shared* costs and their *individual* costs. However, in the grand total of all costs, including the Principal Permittee, these costs are not included to avoid the error of counting them twice.

2.4.1 Program Costs for Permit

With the new permit, costs of the Principal Program have increased significantly. The majority of this was due to the large increase in monitoring, but also the first year of the permit required new materials for businesses and land development communities. Cost for the Permittees' implementation also increased significantly but have tapered off from the first year. In 2010/11 the projected cost of the activities undertaken by the Permittees implementing the stormwater program within their jurisdictions were estimated to be \$31,910,727. This is a large increase over the budgets under the previous permit due to new programs, monitoring equipment and studies required. For FY 2011/12 the estimated costs for all permittees' expenses were still challenging at approximately \$19.5 million. For 2012/13 the estimated costs are about half of what they were a few years earlier, though still significant at \$16 million.

Performance Standard 2-3

<i>Watershed Protection</i>	<input checked="" type="checkbox"/>		

2.4.1 Fiscal Resources

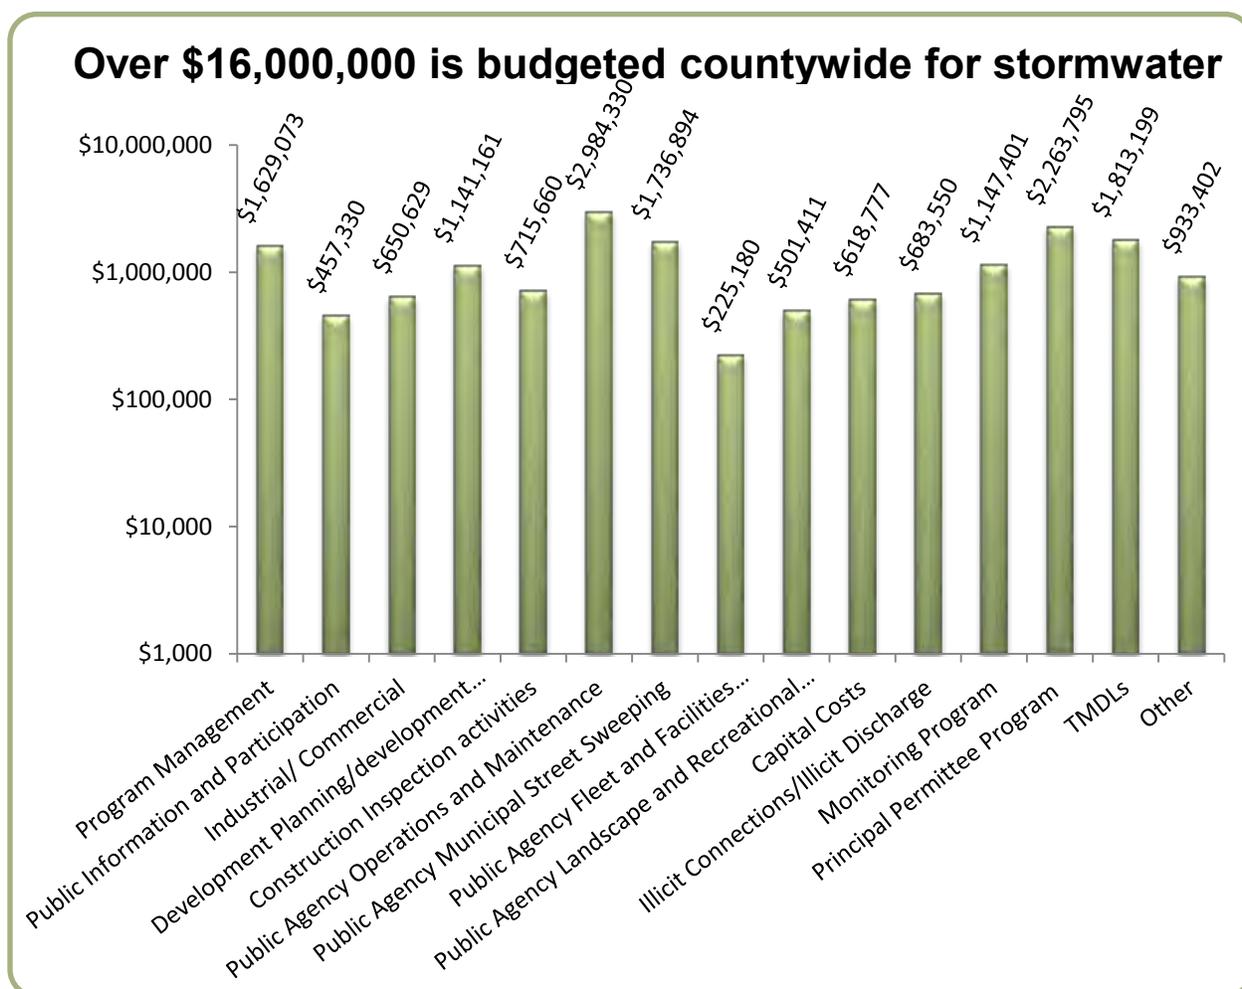

Each Permittee prepares a stormwater budget annually and allocates resources to be applied to the stormwater program. An effective stormwater program must be integrated within the entire management structure of a permittee, which means it transcends divisions and departments, therefore stormwater programs are not always uniquely identified in budgets, but more often integrated into the ongoing programs. Table 2-2 presents the projected stormwater budget for each Permittee for Fiscal Year 2012/13 and Figure 2-2 shows how the countywide budget is divided among the various programs. As expected, there is some variability between the stormwater program budgets reported

by the Permittees, even if normalized by population or geographic size. This variability is due in part to the accounting practices utilized by each Permittee and the allocation of activity costs amongst programs implemented by each Permittee. Variability is most significant when capital improvements are undertaken, these are usually very large and costly projects that may be TMDL driven or assisted by grant funding. These projects do not represent ongoing program costs, but rather investments in infrastructure to help reduce stormwater pollution into the future.

Table 2-2 Agency Annual Budget Update for Stormwater Management Program - Fiscal Year 2012-2013

Program Element	Camarillo	County of Ventura	Fillmore	Moorpark	Ojai	Oxnard	Port Hueneme	Ventura	Santa Paula	Simi Valley	Thousand Oaks	VCWPD	Principal Permittee
II. Program Management	\$ 280,928	\$ 348,820	\$ 10,000	\$ 54,224	\$ 12,000	\$ 132,095	\$ 25,000	\$ 225,000		\$ 198,881	\$ 120,000		\$ 222,125

Other								\$ 10,000	\$ 475	\$ 141,748	\$ 180,000	\$ 210,000	\$ 391,179
Total	\$ 1,211,597	\$ 2,270,500	\$ 100,000	\$ 447,824	\$ 135,500	\$ 2,472,958	\$ 513,450	\$ 1,434,576	\$ 97,535	\$ 2,143,814	\$ 1,460,500	\$ 2,710,000	\$ 2,263,795

Figure 2-1 Countywide Budget FY 2012-13

The Permittees vary significantly in their jurisdictional area and population which can explain some differences in resources dedicated to various program areas. Another example of differences is that some Permittees have privatized streets sweeping and the annual costs are being born by the solid waste rate payers. Yet, a review of the annual budgets produces some nominal findings. As expected, total stormwater budgets trend upwards as population and service area increases. However, increased population doesn't always directly translate into increased revenue available for the program. Seeking new revenue sources to provide the needed resources to comply with the legal requirements of the Permit is an ongoing effort of the permittees.

2.4.2 Funding Sources

Funding sources to implement the stormwater program, including the programs that have been in place long before the permit requirements but are now relied upon to ensure permittees meet permit objectives, are both general and specific funds, taxes, maintenance and user fees, and grants. Other efforts in the county to monitor, cleanup, or otherwise improve stormwater quality by volunteer groups like Ventura Coastkeeper who's efforts can be considered to help implement some stormwater program elements are not included, however, permittee efforts to support volunteer groups in their endeavors are included.

The funding sources used by the Permittees include: Watershed Protection District Benefit Assessment Program, General Fund, Utility Tax, Separate Tax, Gas Tax, Special District Fund, and others (Developer Fees, Business Inspection Fees, Sanitation Fees, Fleet Maintenance, Community Services District, Water Fund, Grants and Used Oil Recycling Grants).

All Permittees except the City of Moorpark gave authorization to use the Watershed Protection District’s Benefit Assessment to finance the activities and requirements. This was done through watershed based Implementation Agreements for the Ventura Countywide Stormwater Quality Management Program. The Implementation Agreements identified the responsibilities of the parties to the Permit and set forth the methodology for using the District’s Benefit Assessment financing to fund the NPDES Stormwater Program in their respective jurisdictions.

The Agreements have been amended over the years and with the new permit a new effort to secure a long term agreement was initiated. The result was a five year Implementation Agreement with all Permittees to replace the original agreement. The Agreement defines the fiscal responsibilities (expenditures and contributions) of all collective parties with respect to the current Permit. It formalizes the Permittees’ commitment to cooperate and to mutually fund an integrated Program of protecting and improving water quality in Ventura County. The five year time frame was designed to mirror the term of the permit. As new permits are written and adopted for Ventura County these agreements will be reviewed, revised, and renewed as appropriate.

Table 2-3 Permittee Population and Area

Ventura County Statistics		
Co-permittee	Population	Area (Sq. Mi.)
Camarillo	65,201	20.0
County of Ventura	92,063	24
Fillmore	15,000	3.2
Moorpark	34,421	12
Ojai	8,156	4.4
Oxnard	200,004	26.9
Port Hueneme	21,887	4.5
Ventura	109,000	32.7
Santa Paula	30,000	4.6
Simi Valley	126,414	42.0
Thousand Oaks	128,000	55.0

3 Public Information and Public Participation

3.1 OVERVIEW

The purpose of the Public Outreach Program Element is to increase knowledge and change behavior of the public to reduce stormwater pollution. By informing the public regarding the impacts of urban stormwater runoff and introducing steps they can take to reduce pollutants from everyday activities runoff quality should improve in both wet and dry weather. In addition to improving water quality, helping the public understand the problems associated with urban stormwater runoff can help build support for the stormwater program.

The Public Outreach Program Element is designed to implement and evaluate a comprehensive short- and long-term public education campaign that will inform the community about how our actions may adversely impact urban stormwater discharges and, subsequently, the local water bodies.

Public education is an essential part of a municipal stormwater program because changing public behavior can create a real reduction in pollutants. When a community has a clear understanding of where the pollution comes from, how it can affect them, and what they can do to stop it, they will be more likely to support the program, change their own practices, and help educate others.

The Permittees are building upon the many successes of the current program. Early in the program, the Permittees identified key elements crucial to establishing a successful outreach campaign. These elements include:

- Watershed Awareness;
- Identification of general and specific goals of the program;
- Identification of target audiences and key messages for those audiences;
- Development of program strategies and plan overview;
- Consistent messaging using a unified “brand name”;
- Development of a watershed based outreach program;
- Development of a model public education/public participation strategy for localization at the Permittee level;
- Development and implementation of a school-aged children education outreach program;
- Development and implementation of food facilities outreach program materials;
- Development and implementation of automotive facilities outreach program materials;
- Development and implementation of industrial facilities outreach program materials; and
- Public Awareness Surveys to measure success and determine needs;

3.2 CONTROL MEASURES

The Permittees have developed several Control Measures and accompanying performance standards to ensure that the Public Outreach Program requirements found in the Permit are met and provide information for optimizing the Program.

The Public Outreach Program Control Measures are organized to be parallel to the organization of the Permit and consist of the following:

Table 3-1 Control Measures for the Public Outreach Program Element

PO	Control Measure
PO1	Public Reporting
PO2	Public Outreach Implementation
PO3	Youth Outreach and Education
PO4	Business Outreach
PO5	Effectiveness Assessment

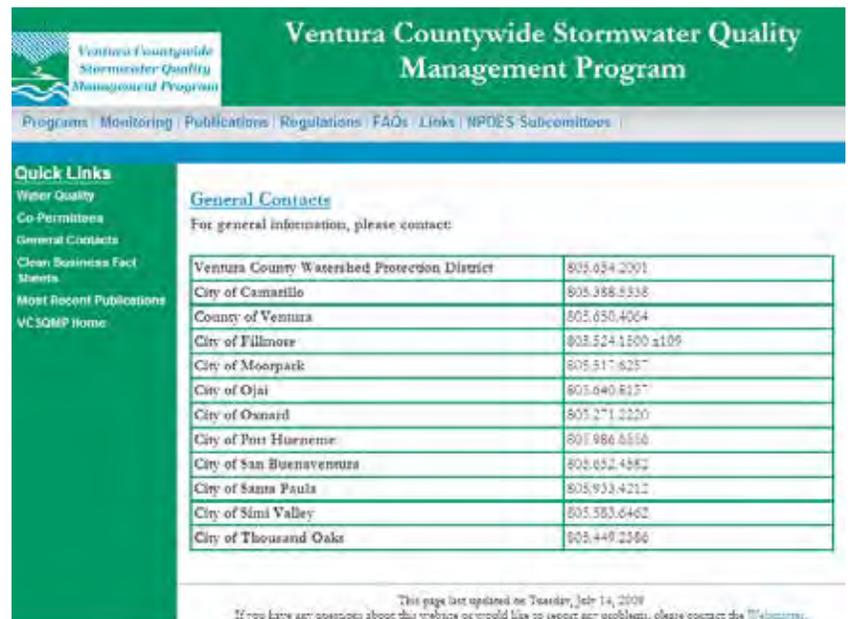

At the end of this chapter these control measures are evaluated to determine the effectiveness of this program element.

3.3 PUBLIC REPORTING - PO1

The purpose of this Control Measure is to identify staff to serve as contact persons and to operate and advertise public hotline numbers to facilitate public reporting of observed water pollution problems. This Control Measure also ensures that through the hotlines, complaint information is forwarded to the appropriate contacts for follow-up and/or investigation.

3.3.1 Identify Staff to Serve as Contact Persons for Public Reporting

Permittees have identified staff to serve as the contact person for public reporting, in many cases more than one staff member will serve in this capacity to ensure that someone is always available to respond. Designated staff members are provided with relevant stormwater quality information, including program activities and preventative stormwater pollution control information.

3.3.2 Maintain Public Reporting Hotline Numbers

The Permittees have two types of phone numbers for the public: one for general stormwater information and one for reporting water pollution problems. The latter number is used by the public to report illicit discharges or illegal dumping into the storm drain system, faded or missing catch basin markers, and other observed water pollution problems. In some cases this number is also used to report clogged catch basin inlets, but

there may be another number for that as well. Staff is also available to provide general stormwater information.

Once a water pollution complaint is received, staff initiates a response within 24 hours to the reported illicit discharges, and within 21 days to illicit connections. For additional summary information regarding use of the hotlines for reporting illicit discharges or illegal connections see the process outlined in Section 8 Illicit Connections and Illicit Discharges Elimination. During the Permit term, the Permittees will consider a web-based reporting form for reporting illegal discharges and illicit connections (see Control Measure ID1), however the timely response needed to stop illicit discharges necessitate the public report to a live person as quickly as possible, so it is considered more appropriate for a website to refer to a phone number.

Performance Standard 3-2

Public reporting information has been listed in the government white pages of the local phone book

3.3.3 Promote/Publicize Public Reporting Hotline Numbers/Contact Information

Contact information for reporting water pollution complaints for all Permittees is updated as necessary and published in the government pages of the local phone book and other appropriate locations. In addition, this contact information is available at several Permittee web sites.

3.4 Public Outreach Implementation - PO2

The Public Outreach Implementation Control Measure provides that outreach be conducted with the residential community and general public to inform these audiences of the impacts of urban stormwater runoff and introduce steps they can take to reduce pollutants in stormwater runoff. Such outreach communicates to the Permittees’ residents and visitors the importance of stormwater quality protection and pollution prevention as it relates to the protection of the local water bodies.

3.3.4 Work with Existing Local Watershed Groups

There are four watersheds in urbanized Ventura County: Malibu Creek, Calleguas Creek, Santa Clara River, and the Ventura River. Each of these watersheds has a watershed organization developed to get stakeholders to work together to identify problems and reach consensus on solutions. The Program's members are involved with these groups and are accomplishing this Permit requirement through their collective effort.

Performance Standard 3-4

Work with existing local watershed groups or organize watershed Citizen Advisory Groups/Committees to develop effective methods to educate the public about stormwater pollution? (by July 8, 2011)			
	Yes	No	In Progress
Ventura Countywide Stormwater Quality Program	<input checked="" type="checkbox"/>		

3.3.5 Educate Ethnic Communities

The Permit requires the Principal Permittee to develop and implement a strategy to educate ethnic communities through culturally effective methods. The Program has previously performed focus groups on Ventura County residents who speak Spanish at home. The information gained through this effort helped the Program understand what needs to be communicated to Spanish speakers and where that communication will be most effective.

To reach the significant Hispanic community in Ventura County, many elements of each campaign throughout the year were created in Spanish. This includes transit shelter and radio ads. Using a multi media mix of newspaper, radio, and transit shelters, Spanish language advertising accounted for 15% of the annual media impressions: 1,094,112. (This figure does not include the BMP fact sheets and other handouts.)

3.3.6 Make Five (5) Million Stormwater Quality Impressions per Year

During the Permit year the Program conducted a comprehensive stormwater pollution prevention advertising campaign. Media plans were negotiated with the goal to maximize target reach and frequency on a limited and fractionized budget. This was particularly true this year when the budget needed to stretch to cover several audiences. To amplify total market penetration, the adult and youth campaigns were scheduled either concurrently (fall) or in quick succession (spring), to take advantage of any overlap in the audiences. Attention was paid to geographical distribution throughout Ventura County as well as adequate coverage in the Latino market. The Program contracted with a full service marketing firm located in Ventura County, theAgency, who was able to consistently obtain low rates and significant bonus elements, including bonus radio commercials and outdoor billboards.

The media chosen for the Community for a Clean Watershed program are objectives-based, balancing the goals of reaching the diverse target audiences within the region at an adequate level of repetition within a limited budget. Tactically, adult and youth efforts are scheduled to overlap in order to amplify the total share of voice within the market. As in past years, attention was paid to geographical distribution throughout Ventura County as well as adequate coverage in the Latino market.

In addition to the more traditional media of cable television, radio, and outdoor transit shelters, cinema ads and posters in local malls were utilized in this year’s plan. Due to its proliferation and ability to reach youth in particular, the social medium Facebook was also added to the Watershed’s Fiscal Year 2011 outreach efforts, both as a Page and utilizing Facebook ads targeted within Ventura County. theAgency was able to consistently obtain low rates and significant bonus elements, including bonus radio commercials and outdoor billboards.

For the three campaigns in the 2010 /11 year, the Community for a Clean Watershed marketing effort plan achieved a total of 6,592,955 gross impressions, as follows:

Table 3-3 Community for a Clean Watershed Gross Impressions

<u>Timing</u>	<u>Campaign</u>	<u>Gross Impressions</u> <u>(Persons 6+)</u>	<u>Youth Impressions</u> <u>(included in total)</u>	<u>Spanish Impressions</u> <u>(included in total)</u>
Fall 2011	Coastal Cleanup	1,623,982		70,000
Fall 2011	Trash Education	3,670,059	989,849	502,712
Spring 2012	Green Waste	<u>1,693,395</u>	--	<u>521,400</u>

Press Releases/Bylines (7)	Various	<u>392,000</u>		
Total Impressions		7,385,262		

Media Outreach Strategy

The media chosen for the Community for a Clean Watershed program are objectives-based, balancing the goals of reaching the diverse target audiences within the region at an adequate level of repetition within a limited budget. Tactically, adult and youth efforts are scheduled to overlap in order to amplify the total share of voice within the market. As in past years, attention was paid to geographical distribution throughout Ventura County as well as adequate coverage in the Latino market.

In addition to the more traditional media of cable television, radio, and outdoor transit shelters, Facebook continued to be an important element in the Watershed’s Fiscal Year 2012 outreach efforts, both as a Page and utilizing Facebook ads targeted within Ventura County. theAgency was able to consistently obtain low rates and significant bonus elements, including bonus radio commercials and outdoor billboards.

For the three campaigns in the 2011/12 year, the Community for a Clean Watershed marketing effort plan achieved a total of 7,385,262 gross impressions, as follows:

Collaboratively, the Permittees continued to execute a variety of outreach activities. The 2011/12 year’s efforts included the following key initiatives, which were created and implemented through theAgency.

Of particular note was the effort targeted to students in Kindergarten through 12th grade. This component, which was directed in part by the information revealed in last year’s web survey findings, effectively reaches this important target audience. Through cost-efficient use of local media, this audience will have

the opportunity to see/hear the Watershed message multiple times, thus having the potential to create long-term awareness and impact.

Performance Standard 3-7

Make a minimum of 5 million impressions per year to the general public related to stormwater quality, with a minimum of 2.5 million impressions via newspaper, local TV access, local radio and/ or internet access.			
	Yes	No	In Progress
Ventura Countywide Stormwater Quality Program	<input checked="" type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>

Fall 2011: “A Day in the Life” Trash

The Fall focus was on trash, building on the YouTube-like commercial created last year, “**We Can Do This,**” which promoted activism, demonstrated the harmful effect of trash in our yards/neighborhoods and encouraged participation by picking up trash in order to protect the watershed. Our ‘hero’ from “We Can Do This” reprises his role in “A Day in the Life,” where he describes a ‘typical’ day in the life of Ventura County’s Watersheds. As he reads from a list of items collected during a recent local Coastal Cleanup Day, the ‘junk’ literally falls out of the sky onto his head. He continues to read and the trash builds up around him until he gets to the figure for the estimated pounds of dog poop when his expression becomes very concerned (knowing what will drop next) and the spot ends.

Frames from “A Day in the Life” TV Spot

A Day in the Life Transit Shelter

Online Web Ad

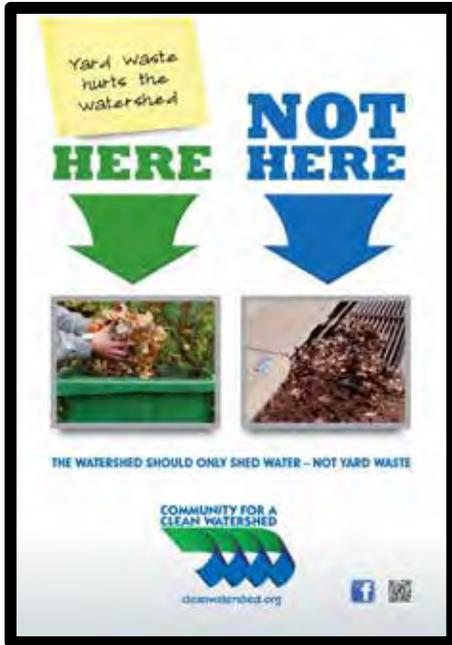

Spring 2012 – “Shouldn’t Have” Green Waste

In Spring, the pollutant of concern was Green/Yard waste, utilizing the Green Waste television spot which brought back the animated couple from our pesticide commercial. This time, our couple has an overgrown yard which after being trimmed back, is washed into the storm drain and eventually to the beach. In an entertaining way, “Shouldn’t have done that” demonstrates that green waste is toxic when rain and sprinklers carry it into the Watershed.

Frames from “Shouldn’t have done that” TV Spot

In the weeks leading up to Earth Day, corresponding radio spots in English and Spanish supported the television message, along with these Green Waste transit shelters:

Green Waste Transit Shelters

Permittee Efforts

On top of what the Program provides for public outreach countywide, the individual Permittees implement their own outreach efforts focusing on local issues and more personal interactions with their residents. Countywide these efforts beyond the Program’s efforts lead by the Principal Permittee made over an additional 6.1 million impressions. Below are some examples of these efforts:

Earthday events countywide help educate residents about pollution

Camarillo

1. Published the following articles in the City of Camarillo City Scene Newsletter:
 - a. July/August 2011: "Save the Date- 2011 Coastal Cleanup Day" (25,100 Contacts)
 - b. September/October 2011: "Ready For Rain? Slopes and Drains Must Be Maintained!" (25,100 Contacts)
 - c. November/December 2011: "Thank You, 2011 Coastal Cleanup Day Volunteers!" (28,000 Contacts)
 - d. January/February 2012: "Do the Right Thing for the Environment" (28,000 Contacts)
 - e. March/April 2012: "Think Before you Drain!" (28,000 Contacts)
 - f. May/June 2012: "Do You Know Where Your Litter Goes?" (28,000 Contacts)
2. Mail out to swimming pool owners with letter and flyer (68 Contacts)
3. Send postcards to 2010 Coastal Cleanup Day volunteers to notify them of 2011's event (137 Contacts)
4. Utility bill insert sent to city customers regarding 2011 Coastal Cleanup Day and advertised cleanwatershed.org website (20,000 Contacts)
5. City Scene TV played "We Can Do It" video and Coastal Cleanup Day Ad from 8/1/2011 through 9/17/2011 (20,000 Contacts)
6. Enviroscape Demonstration at Girl Scouts event at Cal. State Channel Islands (88 Contacts)
7. Email with information regarding Coastal Cleanup Day sent to potential volunteers (31 Contacts)
8. Mail out to Construction Contractors (123 Contacts)
9. Coastal Cleanup Day Proclamation at televised City Council mtg.- PowerPoint and Video Presentation (100 Contacts)
10. Mail out to owners of stormwater post-construction treatment devices requesting maintenance records (146 Contacts, 80 Devices)
11. Mail out (2nd Notice) to owners of stormwater post-construction treatment devices requesting maintenance records (26 Contacts, 17 Devices)
12. Mail out (3rd Notice) to owners of stormwater post-construction treatment devices requesting maintenance records (10 Contacts, 8 Devices)
13. Earth Day 2012 at Camarillo Community Center (180 Contacts)
14. Trash and Debris Removal Assistance Letter sent to shopping center owners (42 Contacts)
15. Two "Calleguas Creek Watershed - Keep it Clean" signs were posted at Calleguas Creek in Camarillo

County of Ventura

1. 20,300 inserts were mailed out with the Integrated Waste Management Division December, 2011 monthly trash bill for unincorporated residents served by IWMD for trash collection, providing information for proper disposal of household hazardous wastes, electronic waste, and medication disposal. 100 horse manure BMPs were handed out during a Household Hazardous Waste Event in the Santa Rosa Valley area (which has a large percentage of residences with horses.)
2. 176 fliers were delivered to Oak Park residents related to illicit discharge prevention and 90 fliers on stormwater BMPs for pool cleaning were provided to residents that aerial imagery indicated a pool in the backyard. The area was targeted for compliance with the Malibu Creek Bacteria TMDL.
3. The following schools serving County of Ventura unincorporated area were visited during the 2011 fall KCAQ school tour, which included educational outreach to middle and high school students with a message about preventing littering and trash impacts to local waterways:
 - a. September 14 - Rio Mesa High, Oxnard: 950 students attended (covers County unincorporated RSBW Trash TMDL tributary areas)
 - b. September 28 - Rio Vista Middle, Oxnard: 650 students attended (covers County unincorporated RSBW Trash TMDL tributary areas)
 - c. October 24 - Newbury Park High, Newbury Park: 1,200 students attended
 - d. October 31 - Nordhoff High: 700 students attended (covers upper Ventura River County unincorporated communities of Meiners Oaks and Mira Monte)

- e. November 7 – Adolfo Camarillo High: 1,200 students attended (covers County unincorporated RSBW Trash TMDL tributary areas)
- f. November 18 – Rio de Valle Middle School, El Rio: 600 students attended (serves El Rio)

Moorpark

1. The City of Moorpark participates in Coastal Cleanup Day. The event was on September 17, 2011 during FY 2011/12. Thirty-seven volunteers covered approximately six miles of the Arroyo Simi, collecting 300 pounds of trash. Many volunteers who had participated in previous years noted that there appeared to be less trash around than in the past.
2. Public information on stormwater protection is also provided during Moorpark Country Days. Country Days was held on October 1 during FY 2011/12. An estimated 4,000 people attended the event.
3. The City offers free hazardous waste collection events to residents of Moorpark. In FY 2011/12, 290 households used the service.
4. Mass mailing includes the City's quarterly newsletter that went to approximately 13,200 households.
5. In FY 11/12, the City did NPDES messages in two quarters. NPDES messages were also mailed in four solid waste bill inserts to 8,008 households each time.

Ojai

1. Eagle Scout project posting "don't dump" signs on accessible water courses.
2. Ojai Day - October 2011 - booth literature distribution.
3. Contact local school officials to distribute brochures.

Oxnard

1. The City of Oxnard has established the OxnardNews.org website to publicize community events such as Earth Day and Coastal Cleanup day. Community members can access the website to view calendars of upcoming events, view press releases, or even watch videos of past events. Coastal Cleanup Day is an event that consistently receives huge community support. City of Oxnard Outreach Specialists will post a press release containing information about the event at least one month in advance to assist community volunteers with pre-registration and planning. This past September, members of the Oxnard community participated in Coastal Cleanup Day at the Ormond Beach Wetlands and Oxnard Beach Park. The City of Oxnard Education and Outreach Specialists estimate that about 3,600 contacts were made at America Recycles Day, Earth Day, and the Compost Workshop. In addition, the City of Oxnard added an additional web page entitled "Oxnard's Green Sustainability Programs". This page provides info on various programs designed to develop and nurture a balanced connection between natural resource conservation, economic vitality, and quality of life.

Port Hueneme

1. The City has a few citizens that perform trash clean-ups along our green belt and also has a group that performs beach cleanups separate from the Coastal Cleanup activities. The City is also preparing to administer training with Neighborhood Watch Groups in the near future. The City also had a booth at the annual Hueneme Beach Festival that included stormwater educational materials and water conservation practices.

Simi Valley

1. Throughout the year the City of Simi Valley participated in several community events to help promote pollution prevention and improve stormwater awareness within the community. During the reporting period six Household Hazardous Waste events were held where 53,818 pounds of

hazardous waste was collected from the residents of Simi Valley. Stormwater informational brochures were handed out to each of the 802 participants at the events.

2. An Electronic Waste Collection event was held on April 21, 2012. Informational BMP brochures designed for residents were also handed out at these events.
3. The City took part in the Earth Day event held on April 21, 2012 at the Simi Valley Town Center and the City Street Fair held in May. Stormwater demonstrations were given using an Enviroscape to approximately 250 adults and children at Earth Day and the Moorpark College Environmental and Multicultural Day. The City had a staffed booth and informational brochures were handed out at the Street Fair.
4. The City's Environmental Compliance Inspectors took the time to educate residents and businesses during 137 compliance responses.
5. The City took part in the annual Coastal Cleanup Day on September 17, 2012, 230 volunteers collected approximately 1,700 pounds of trash from a three mile stretch of the Arroyo Simi.
6. City staff issued 141 Pool Discharge Encroachment permits, handing out our Swimming Pool Maintenance BMP brochures with each encroachment permit. The Swimming Pool Maintenance brochures was also given out with Building and Safety permits for new pools.

Both Girl and Boy Scouts have been used by several Permittees for cleanup and other outreach events.

Thousand Oaks

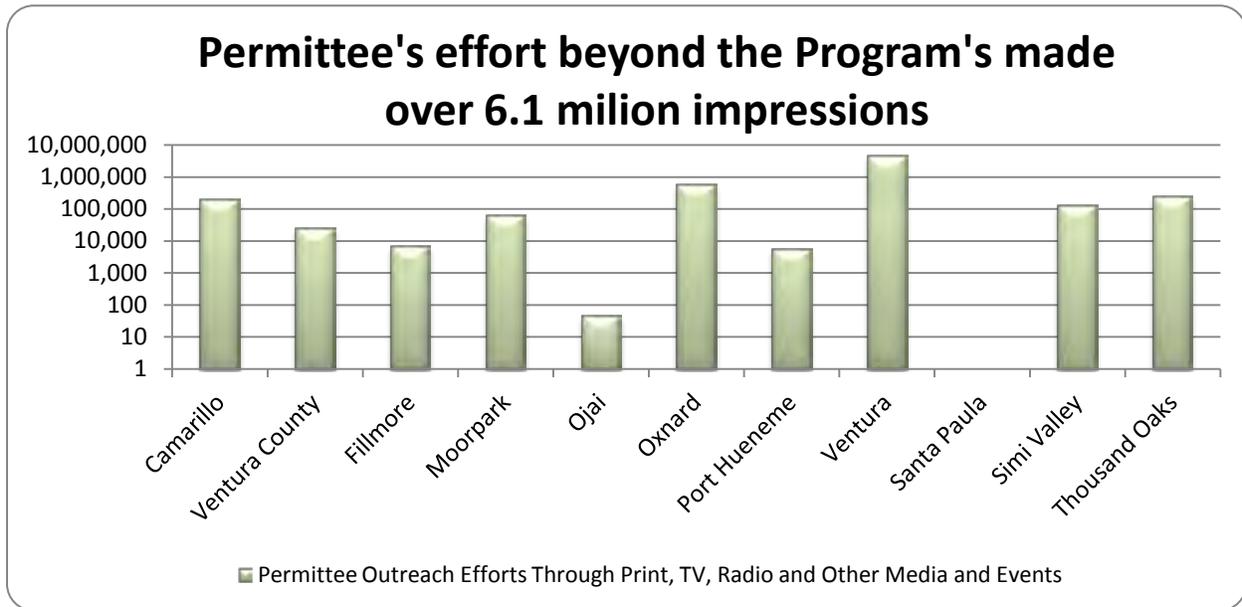

1. Community Cleanup Day—The City of Thousand Oaks sponsored a collection event of waste materials on June 2, 2012. At the event, about 1,238 residents brought 188.67 tons of trash, 42.59 tons of green waste and 4.29 tons pounds of e-waste for free disposal.
2. Coastal Cleanup Day—On September 17, 2011, 268 volunteers worked together to clean about 3.1 miles of channel and creek in and around Borchard Park; a channel in Thousand Oaks Community Park; and an area of the Arroyo Conejo Creek in Thousand Oaks. The volunteers were from the general public, a Girl Scout group, and a group recruited from the Amgen Company. This combined effort removed 1467 pounds of litter and debris and about 108 pounds of recyclable materials from creek areas.
3. Freeway Ramp and Interchange Collection Program (also called Adopt-A-Highway)—From July 1, 2011 to June 30, 2012, about 14,500 pounds of trash and debris were removed from 13 freeway on-ramps and exits and one freeway interchange in the City of Thousand Oaks.
4. City of Thousand Oaks Household Hazardous Collection Program—Eleven collection events were held once a month during the 2011/12 fiscal year. Over the year, 4,851 residents brought in 513,144 pounds of household chemicals waste materials including fertilizers, cleaning chemicals, paints, insecticides, electronics, used motor oil, and unused pharmaceuticals. Material re-use conducted under this program recycled 15,725 pounds of material for beneficial uses instead of disposal.
5. The City of Thousand Oaks sponsored Arbor Earth Day on April 28, 2012. Representatives from the City's Resource Division provided information to attendees about watershed and solid waste issues and how to improve them. Informational brochures on these topics were available to all. More than 3,000 people attended this event.
6. An outreach event was held at Thousand Oaks Hyatt Hotel on April 20, 2012. Informational displays and a question and answer format educated participants about stormwater and solid waste topics. About 25 people attended.
7. Utility Bill Inserts—Promotional/informational inserts were prepared and distributed for Community Cleanup Day and Arbor Earth Day with a run of 33,000.
8. Thousand Oaks stormwater personnel made presentations centering on water quality issues caused by urban runoff at the following public schools: Thousand Oaks High School (2/25/12) and Westlake High School (4/4/12). These half-hour presentations were viewed by about 160 students and they included a message about how to protect a watershed.
9. Public Works Week—May 23rd and 24th 2011—About 17 Conejo Valley schools brought more than 588 3rd grade students and about 169 adults to see examples of the activities and equipment that are used to by the City of Thousand Oaks to maintain its infrastructure. To inform participants about protecting stormwater quality, a table-sized watershed model was marked with colored pens to represent commonly used yard chemicals. Children participated by making simulated rain with spray bottles to see these suggestive pollutants contaminate the creeks and lake as runoff.
10. Neighborhood Cleanup Program—Fiscal Year 2011/12—The City sponsors free placement of general refuse and green waste 40-yard dumpsters, when neighborhoods follow a procedure to generate enough interest and participation. There were 43 such events where two dumpsters were taken out to

neighborhood locations. In total, 141.7 tons of trash waste and 40.97 tons of green waste were received and taken to proper disposal.

Ventura

1. The mission of the City of Ventura's volunteer based programs is to showcase and preserve Ventura's natural resources and beauty. The programs include the following: Seven Community Park clean ups with 147 volunteers working to remove litter from public areas; Two Earthday sites with 595 volunteers; Community cleanups on the Westside and Eastside with 40 volunteers; Ventura River bottom annual clean up with 602 students from Cal Lutheran; Ventura Yacht Club beach and water clean ups with 42 volunteers; Seaward Beach cleanup with 75 volunteers; Trashathon, held at ten sites with 267 volunteers; and five Coastal Clean Up with designated sites with 792 volunteers. These events serve to further educate the residents in good stewardship and stormwater pollution prevention.
2. In addition, the City of Ventura staff participated in other community outreach events and offered stormwater education as a component of its message. Some of these included the following: Farmer's Markets, Home and Garden Show, Eco-Fest, Summerfest, Hillside Music Festival, Botanical Garden, Festival in the Park, and the 4th of July street fair. The City also hosted three workshops on Ocean Friendly Gardens that serve to educate residents on the proper application of water, fertilizer, pesticides, and herbicides to help eliminate runoff into our watersheds. City staff provided outreach and education to 5400 students in the Ventura Unified School District classrooms including a section on stormwater and the effect of runoff on our watersheds.

Figure 3-1 Impressions made through Permittee efforts

3.3.7 Storm Drain Inlet Markers and Signage Discouraging Illegal Dumping

The Permit requires each Permittee to label all storm drain inlets that they own with a legible “no dumping” message and to maintain them. The Permit also requires signs with prohibitive language (i.e., discouraging illegal dumping) to be posted and maintained at designated public access points to creeks, other relevant waterbodies, and channels.

Performance Standard 3-8

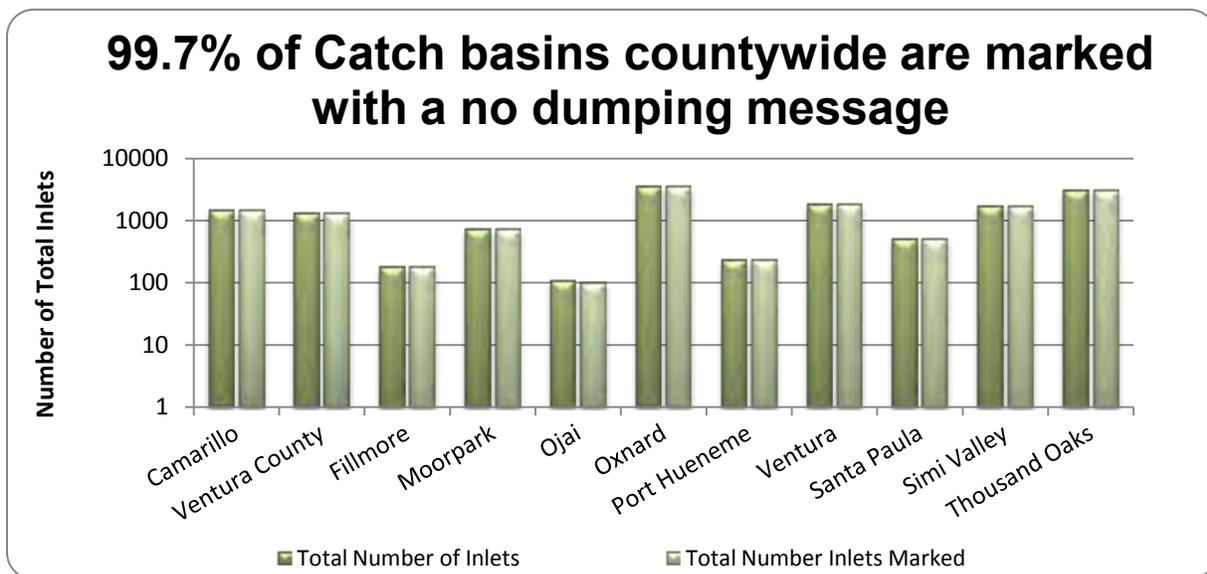

Label storm drain inlets with a “no dumping” or equivalent message

Label Storm Drain Inlets with “No Dumping” Message

As of 2011/12, the Permittees had completed labeling or marking the curb inlets to their entire storm drain system. Permittees maintain their inlet signs by reapplying stencils/markers as they wear out (see Control Measure PA5) and applying stencils/markers to new inlets as they are installed. Markers at curb inlets have varying useful lives due to the materials from which they are constructed (e.g., paint, thermoplastic), their position (e.g., on top of curb, on face of curb), and wear factors (e.g.,

traffic, street sweeping, sunlight). As a result, the Permittees have different programs to maintain curb inlet markers within their respective jurisdictions. Some Permittees replace a portion of their markers each year, whereas others re-mark all inlets every few years. Regardless of the specific inlet marker practice, all Permittees understand the importance of storm drain inlet markers to the education component of their program and are committed to installation and maintenance of the markers.

Figure 3-2 Catch Basin Labeling

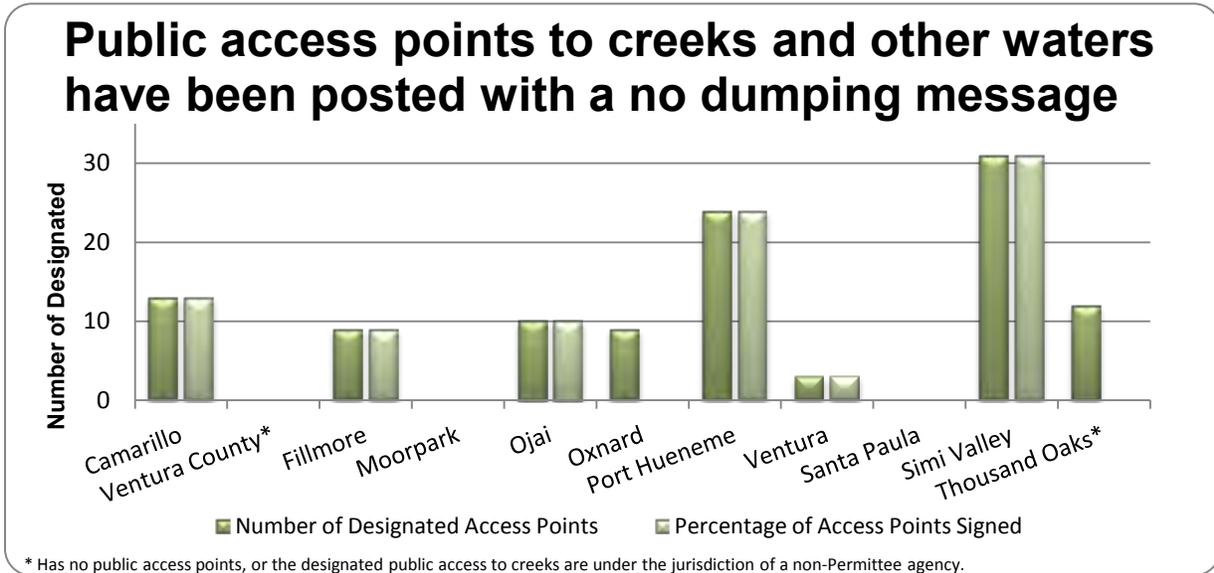

Post Signs with Language Discouraging Illegal Dumping

The Permittees are required to designate appropriate access points to the creeks and channels within their jurisdiction for the placement of signs with prohibitive language to discourage illegal dumping. Each

Permittee is responsible for designating the appropriate access points to creeks and channels within their jurisdiction, which requires field verification and mapping. In some cases a Permittee may not have any designated public access points or they are under the jurisdiction of a special district outside a Permittee’s jurisdiction.

Figure 3-3 Public Access Point Signage

3.3.8 Educational Materials

The Permittees are required to distribute stormwater pollution prevention educational materials covering specific types of pollutants to specific businesses. The businesses to be targeted with these pollutant-specific educational materials include automotive parts stores; home improvement centers, lumber yards, and hardware stores; and pet shops and feed stores. In addition, the Permit requires the Permittees to continue the existing outreach program to residents on the proper disposal of litter, green waste, pet waste, proper vehicle maintenance, lawn care, and water conservation practices.

Public access sign

Retail Partnership Brochures: Gardeners, Pet Owners, Car Owners (Due July 8, 2011)

Three Watershed Protection Tip pamphlets aimed at residents were created to encourage best practices in their homes. These brochures were distributed to targeted retailers called out in the permit to reach the population that is likely involved in the activities. Each colorful pamphlet defines the Watershed, explains the storm drain system, how polluted water is damaging and gives both overall and topic-specific tips for how to keep the Watershed clean. For example:

- Gardeners: discuss plant selection, irrigation, fertilizer and pesticide practices, integrated pest management and yard maintenance
- Pet Owners: safe methods for handling and disposing pet waste, for both cats and dogs
- Car Owners: do-it-yourself clean vehicle care practices for fluids, tires, batteries and car-washing

Retail Partnership Brochures

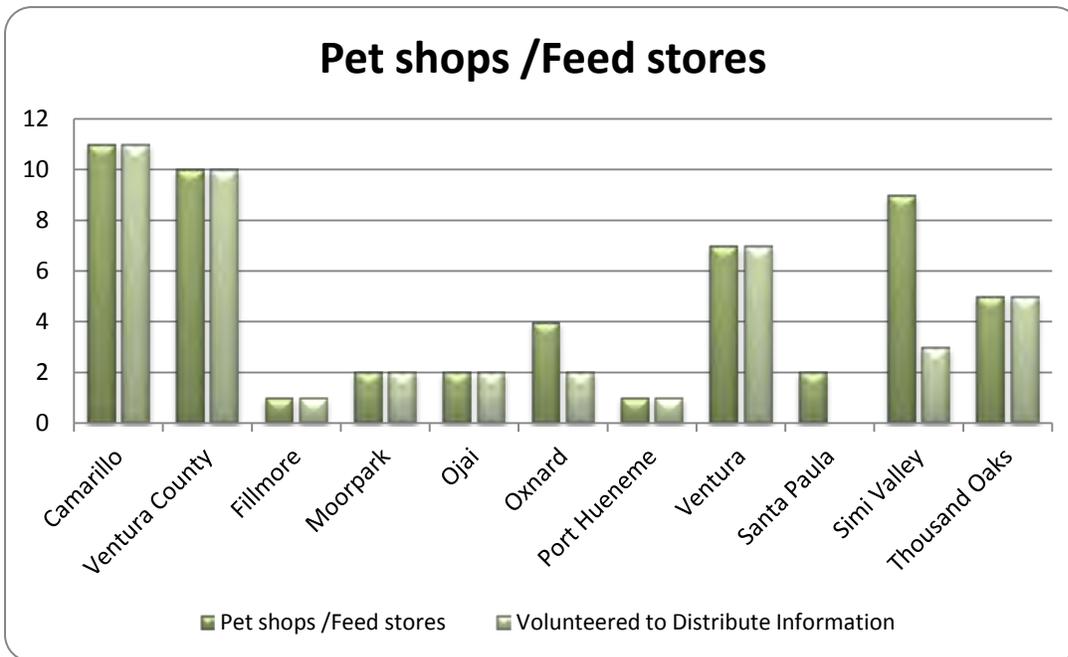

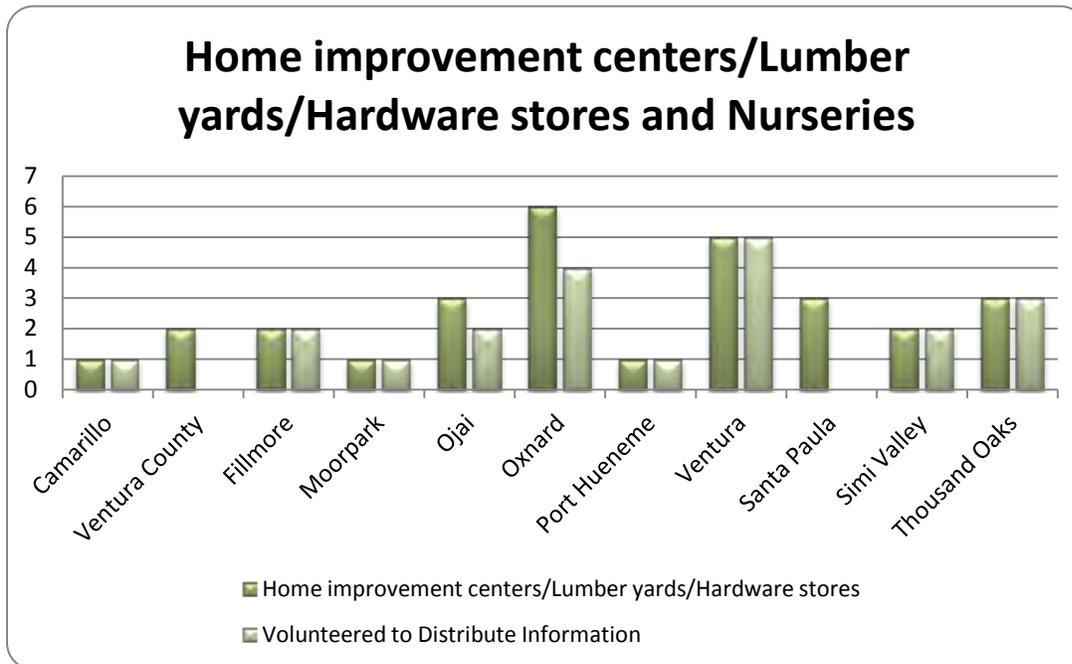

Figure 3-6 Summary of Retail Partnership –Pet Shops

3.3.9 Maintain and Update the Countywide Stormwater Website

The Permit requires the Permittees to maintain the Countywide stormwater website (www.vcstormwater.org). This is the website specified by the Permit, but the Permittees also use cleanwatershed.org primarily for outreach, as described earlier under “activity-specific outreach to residents”. The Community for a Clean Watershed Web site (cleanwatershed.org) is the primary mechanism used by the Permittees to reinforce the various public outreach messages as well as make available a network of resources to help the web viewer make informed decisions. The website is updated on a regular basis to add relevant campaign materials as well as educational materials.

In addition, the website is required to include pollutant-specific educational material addressing (at a minimum) information on the proper disposal, storage, and use of the following:

- Vehicle waste fluids
- Household waste materials
- Construction waste materials
- Pesticides and fertilizers (including IPM)
- Green waste (including lawn clippings and leaves)
- Animal wastes

Community for a Clean Watershed Website

Community for a Clean Watershed Website

The cleanwatershed.org website continues to reinforce the various public outreach messages as well as make available a network of resources to help the web viewer make informed decisions. The website is updated regularly to add relevant campaign materials as well as educational materials. Unique visitors to the website were up 15% over last year with 2,895 people coming to the site over 4,100 visits and viewing an average of 1.9 pages.

Performance Standard 3-9

Maintain the stormwater Web site (www.vcstormwater.org)			
	Yes	No	In Progress
Ventura Countywide Stormwater Quality Program	<input checked="" type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>

The Countywide Stormwater Web Site (www.vcstormwater.org) is periodically updated to include pollutant-specific educational materials for businesses and do-it-yourself homeowners. Facts sheets have been developed over the life of the program and include educational materials on the proper disposal, storage, and use of the following pollutants:

- Vehicle waste fluids
- Household waste materials
- Construction waste materials
- Pesticides and fertilizers (including IPM)
- Green waste (including lawn clippings and leaves)
- Animal wastes

3.3.10 Community Events

The Permit requires the Permittees to individually and collectively organize community-oriented educational activities and events and to participate in countywide events focusing on stormwater quality. The main countywide event for the stormwater program is Coastal Cleanup Day.

The 26th annual California Coastal Cleanup Day was held this year on September 17, 2011. Nearly 72,000 volunteers turned out across California to help pick up trash and prevent it from spreading in our coastal and inland waterways. Statewide, the volunteers picked up more than 1.3 million pounds of trash and recyclables. Internationally, when combined with The Ocean Conservancy's International Coastal Cleanup Day which is held on the same day, the event becomes one of the largest volunteer events of the year. Families, students, service groups and neighbors all work together to show their support for our shared natural resources while helping reduce and prevent the impacts of marine debris.

The Ventura County Coalition for Coastal and Inland Waterways (VCCIW) coordinates the event in Ventura County. Representatives of the stormwater Permittees serve on the VCCCIW and have been actively involved in organizing Ventura County’s Coastal Cleanup Day efforts since 1996. The VCCCIW conducts advertising campaigns, finds sponsors, coordinates materials receipt and pickup, and works with site captains to organize site access permission and trash hauling. The California Coastal Commission oversees the California Coastal Cleanup Day and provides some advertising materials and assistance as needed.

Coastal Cleanup Day had 3,165 volunteers covering a distance of 36 miles at 22 sites countywide and collected 12,810 pounds of trash, and 1,880 pounds of recyclables.

At Ventura County’s 2011 Coastal Cleanup Day, 3,165 volunteers at 22 sites countywide collected 12,810 pounds of trash and 1,880 pounds of recyclables, and covered a distance of 36 miles. Not only does the event remove a significant amount of trash, but each item that is picked up is tallied by category, providing a wealth of information about the types of items that are being found. This information is useful for shaping future public outreach campaigns.

This year, the “bring your own bucket, bottle, and gloves (BYOBGG)” pre-campaign continued. The BYOBGG campaign aims to make Coastal Cleanup Day a zero waste event by having participants bring their own reusable waste buckets, gloves, and water bottles, thereby reducing the volume of trash generated at the event. The success of the 2010 campaign continued in 2011, as volunteers pick up more trash and become more aware of the trash they are generating, its proper disposal, and the effect it has on stormwater quality.

Performance Standard 3-10

	Yes	No	In Progress
Ventura Countywide Stormwater Quality Program	<input checked="" type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>

3.3.11 Pollutant-Specific Outreach

The Permit requires the Permittees to coordinate to develop outreach programs that focus on the following specific pollutants of concern: metals, urban pesticides, bacteria, and nutrients. For effectiveness in delivering these messages they were incorporated into the other outreach programs requirements of a multimedia campaign and retail partnerships with auto shops, pet stores and home improvement stores/nurseries.

To focus on nutrients good gardening techniques were identified as a more understandable surrogate for the public as communicating that “nutrients” are a bad thing would create an additional hurdle to the ultimate goal of changing behavior. This information along with pesticide BMPs were distributed at retail nurseries throughout the county. Bacteria from pet waste have been an ongoing target of the program and new material was created during the permit year and given to pet stores to distribute. As stated in the permit the metals pollutant-specific outreach is addressed through the industrial-commercial inspection program.

3.5 YOUTH OUTREACH AND EDUCATION – PO3

This Control Measure ensures that the Permittees either provide school districts within the County with outreach materials (including, but not limited to videos, live presentations, and other information), provide funds to the Environmental Education Account to educate school-age children about stormwater pollution, or submit a Youth Outreach Plan.

Educational outreach to children is an important way to affect a change in behavior. Outreach to children not only changes behavior of the next generation, but children also act as watchdogs over their parent's behavior. Because of this the Program and the individual Permittees have been conducting public outreach with a youth component for many years. Their experience with the local schools in Ventura County and developing programs targeting school-aged children have provided valuable input in the selection of the youth outreach option and the development of a Youth Outreach Plan (Plan) submitted to the Regional Board in July of 2009.

The document summarizes the Program's experience in developing and presenting outreach material to school-aged children, and demonstrates how that experience led to the rationale behind the selection of the Permit required Youth Outreach Plan option. The Plan is described in detail and includes the ground work of identifying what Ventura County youth know about stormwater pollution, where they get their information, and which watershed pollution concepts need additional development. This information was then used to prepare the creative objectives for a media campaign aimed at changing behavior to improve the quality of stormwater runoff. The target audience includes Ventura County youth from kindergarten through high school. The media outlets, broadcast frequency and number of impressions expected are outlined in the media campaign. Finally, the Plan includes methods of measuring program effectiveness and providing feedback for continual improvement of the Youth Outreach Plan to give the next generation the understanding needed to improve the stormwater runoff quality in Ventura County.

Community for a Clean Watershed's efforts towards youth continued to build on last year's outreach when a specific plan was created to reach 50% of all Ventura County school children (K-12) once every two years to comply with the Permit. With less than 150,000 school aged children enrolled in Ventura County schools, this translates to reaching approximately 75,000 in that target every two years. While that goal was met and exceeded, the Community for a Clean Watershed continues to speak to this important audience with a targeted media plan and a creative strategy that appeals to youth. Television, radio, and mall posters garnered 989,849 impressions – thus reaching this audience with significant repetition. In addition, the Facebook page has a sizeable percentage of young fans, allowing for a consistent message to be delivered to youth.

KCAQ School Tour – On-Campus with Middle and High School Youth

Ventura County's Community for a Clean Watershed launched a new youth outreach campaign in FY12 to help reduce trash in the county's watershed. Q104.7-FM radio on-air personalities Joey Boy and Quay visited 26 Ventura County middle and high schools in fall 2011 to spread the word about keeping trash out of the county's waterways, storm drains and off local beaches. During the school tour, students were treated to prizes and giveaways as well as a powerful demonstration of the 13,763 cigarette butts and filters collected at last year's local Coastal Cleanup Day. The awareness campaign's message, which focused on "*A Day in the Life of Ventura County's Watershed*," was brought home to over 23,000 school-aged children at lunchtime events. In addition to the 60-second commercials, on-air radio elements included 35 weekly promotional announcements voiced by a popular personality, giving an endorsement

of the message. Posters were developed and displayed to further tie the message into the school events and a Watershed bookmark was given to all attendees as a reminder.

A couple photos from the KCAQ School Promotion

Bookmark Givaway

Facebook Page

With over 570 fans, the Facebook page allows the Community for a Clean Watershed to keep Ventura County residents and youth engaged and works in conjunction with other outreach. Consistent posts create ongoing communication with fans that are likely to be socially aware. Posts are engaging, including information about local events for Earth Day and/or Coastal Cleanup Day, and interesting local facts.

Sample Facebook Posts

3.4 BUSINESS OUTREACH – PO4

The Permit requires the Permittees to develop and implement both a corporate outreach and a small business assistance program to educate and inform corporate franchise operators, local facility managers, and small businesses about stormwater regulations and BMPs to reduce the discharge of pollutants in stormwater.

3.4.1 Corporate Outreach

Develop Corporate Outreach Program (due by July 8, 2012)

The Permittees must work with other regional or statewide agencies and associations such as the California Storm Water Quality Association (CASQA) to develop a Corporate Outreach program to educate and inform the following corporate franchise operators and/or local facility managers (at a minimum) about stormwater regulations and BMPs.

- Four (4) Retail Gasoline Outlet (RGO) Franchisers
- Four (4) Retail Automotive Parts Franchisers
- Two (2) Home Improvement Center Franchisers
- Six (6) Restaurant Franchisers

Educational materials for RGOs, and restaurants have been developed by the Permittees and are distributed to local facility managers during inspections. These facilities are inspected every two years. During the inspection the inspector meets with the facility manger, effectively complying with this permit requirement. Automotive part stores are included in the retail partnership program to help educate the consumers shopping at their locations. The local facility manager's permission is needed to display the brochures, at this opportunity regulations and BMPs are explained. Under the nursery inspection program some Permittees are including home improvement centers due to the size of their gardening sections. Again the business inspection program satisfies the requirement by meeting with the local facility manager during the inspection.

3.4.2 Business Assistance Program

Best Management Practices Fact Sheets

Targeting types of businesses that have significant potential to contribute to stormwater pollution, Watershed Protection Tips one page fact sheets were created to outline best management practices for six categories of activities. Each BMP fact sheet is available on the Community for a Clean Watershed website, where they can be read or printed for distribution. 10,800 were printed for distribution through Permittees.

Provide Consultation Regarding Business Responsibilities

On-site, telephone or e-mail consultation is required to help business reduce the discharge of pollutants. The Permittees provide on-site consultation regarding the responsibilities of businesses to reduce the discharge of pollutants, during inspections; this requirement is covered in Section IV Industrial Commercial Programs. These trained and knowledgeable inspectors are also available to respond to questions via phone or email.

Best Management Practices Fact Sheets

Distribute Educational Materials to Specific Businesses

As mentioned above, the Industrial Commercial Program is responsible for the distribution of information to businesses. This occurs mostly at inspections, but may also be done when obvious problems are reported. An opportunity to disseminate this information to new businesses before they are in operation is through the business license program. All businesses need a business license to operate legally in a jurisdiction. It is at that time that the permittees are able to distribute information regarding stormwater regulations and appropriate BMPs for their operations. The Program has developed many specific fact sheets over the years for this purpose. The fact sheets may be distributed with the business license, or the proprietor may be directed to the website for the information.

3.5 EFFECTIVENESS ASSESSMENT – PO5

3.5.1 Behavioral Change Assessment Strategy

The Permit requires the Permittees to develop and implement a behavioral change assessment strategy based on current sociological data, and studies to determine whether the Public Outreach Program is demonstrably effective in changing the behavior of the public.

The Ventura County Watershed Permittees are committed to tracking performance of their outreach efforts. To that end, periodic research surveys are conducted to measure awareness, perceptions and the actions taken by Ventura County residents to protect the local Watershed. The research also gives insight about whether outreach messaging is effective along with providing some insight into local media preferences. The following summarizes the 2012 Adult Research Survey, which is the fourth survey since outreach started five years ago.

Performance Standard 3-12

Develop and implement a behavioral change assessment strategy based on current sociological data and studies to determine whether the Public Outreach Program is demonstrably effective in changing the behavior of the public.			
	Yes	No	In Progress
Ventura Countywide Stormwater Quality Program	<input checked="" type="checkbox"/>		

3.5.2 Adult residential panel survey – June 2012

Methodology

A web survey was used as the method of data collection. There were 30 completed surveys from each of the 10 cities and unincorporated areas of Ventura County. Study participants had to be involved in decision making for their home and were required to live in Ventura County for at least 2 years. In addition, they were recruited according to specific demographic criteria, which have evolved somewhat over the four survey periods to better reflect the changing demographics of Ventura County.

The study asked questions on how the responder felt about the seriousness of different environmental problems; whether they agreed with the accuracy of statements regarding the environment and responsibility, the impact of pollutants on the environment, and their concern for the environment; finally respondents were asked if they had adopted any new behaviors to protect the environment.

The following highlights the changes in understanding, evolving attitudes and the most likely watershed protection behavior practices:

Highlights

- Pollution of the ocean is viewed with the highest rate of seriousness (62%), a 3% increase since 2010.
- Perceived seriousness of pollution of local lakes, creeks, and rivers were rated equal to litter on the beach (50%).
- There was a significant increase in understanding both watershed definition and characteristics in 2012/2010, 5% and 7% respectively.
- Possibility of polluted runoff without rain (87%)
- The inclination to consider the health of the watershed as an individual’s responsibility was slightly higher, 4%, (70%)
- In the current study, understanding ‘toxic yard runoff prevention’ dropped -6% (46%), but in general a weak result for all four surveys.
- The same pollutants were perceived as having a higher negative impact 2012/2010, but at significantly increasing levels:
 - Used motor oil 4% (89%)
 - Cigarette Butts 13% (84%)
 - Driveway fluids 6% (83%)
 - Litter 8% (82%)

- Weed Killer/Herbicides 7% (81%)
- Garden Pesticides 3% (74%) *Seriousness trending upward.*
- Pet Waste 17% (68%)
- Lawn Fertilizers 11% (63%) *Seriousness trending upward.*
- Of greatest concern were the following:
 - Pollutants draining -3% (83%)
 - Locally caught fish (74%)
 - Impact on plant/animal life -6% (72%)
 - Swimming in polluted water (71%)
 - Keeping gutters/storm drains clear -4% (70%)
 - Litter on streets and highways -8% (61%)
- Respondents claim to have adopted, on average, 2.54 watershed protection practices in the past year (down from 4 in 2010) and say they have been following best practices for more than one year. (Same as 2010 in slightly different priority)
- The behaviors most frequently practiced were;
 - Picking up litter in front of one's home or business, 5% (87%)
 - Pick up pet waste, -11% (86%) among those who own a pet
 - Take used motor oil or car fluids to a designated disposal/recycling center, -5% (83%) among those who practice this
 - Check for leaks from your automobile, (80%)
 - Use a broom rather than hose to sweep, -3% (77%)
 - Reduced usage of pesticides in general, 3% (73%)
 - Read directions before applying pesticides (70%)
- Half maintain that the responsibility of their yard/landscaping lies with their gardener. Sample is similar to 2010 at 49%.
- Overall, 35%, (a significant 7% increase over 2010) of the sample was able to recall one or more of the various ads.
- 33% of respondents were able to recall hearing or seeing something regarding watershed protection, (-4%) since 2010.
- Outdoor signs were recalled most and "Gutter Pick It Up" had the highest recall (18%).

Insights

- Overall there is a moderate increase in concern over litter issues from 2010 with biggest increase over litter on the beach +7%.
- Overall, concerns expressed in the current survey are slightly higher than 2010 levels.
- Most significant increases were also focus of outreach and include pet waste, cigarette butts, yard runoff and yard waste.
- For the most part, the differences in the understanding and perceived levels of watershed pollution between those who do their own landscaping and those who have a gardener is not very different.
- However, in terms of translating their perceptions into actions/behaviors those who landscape themselves are far more likely to adopt corrective behaviors than those who have a gardener do the landscaping.
- Demographically speaking, the core group that demonstrate both an understanding of the problems and are willing to "pitch in" include:
 - More Caucasians;
 - those in the 35-54 age range;
 - home owners; and

- female.
- Educational and income levels did not reveal significant differences.

Trends

- There is a slight declining trend for individual responsibility and increasing trend for county responsibility.
- Although still relatively high, extreme levels of concern over issues surrounding watershed pollution are trending downward.

Summary

- Perceived seriousness of watershed pollution-related issues are slightly higher,
- Significant increase in the understanding of a ‘watershed’ and recall of our outreach messages,
- Recognition of the serious impact of various pollutants is trending upward,
- Majority believe that our watersheds are polluted and express concern over the impact it will have on their family, but...
- Concern over watershed pollution-related issues of greatest concern is trending down and the number of ‘new’ behaviors decreased.

Opportunity

- Make people ‘care’ enough to connect their understanding, perceptions and concerns into a willingness to take greater action.

3.5.3 Summary of Effectiveness

In its seventh year of developing educational public outreach campaigns, brochures, and posters, the Clean Watershed website and now a Facebook page, the Community for a Clean Watershed program continues to successfully raise awareness among Ventura County residents on the issues impacting the health of Ventura County’s watersheds. This year, several elements were added, achieving the following:

- Generated a second commercial in the trash series, capitalizing on a spokesperson who appeals to all ages – and graphically driving home the message of how much trash is added to the local Watersheds.
- Crafted elements to complement the “Day in the Life” campaign, including radio, transit shelters, and posters.
- Built on two years of a youth campaign, generating almost a million impressions to Ventura County students.

The Community for a Clean Watershed logo

- Delivered the general Watershed and trash messages into middle and high schools through a collaborative effort with a popular local radio station.
- Reminded residents about positive actions they can take with their yard waste to protect the Watershed.
- Established consistent communications with our Community for a Clean Watershed Facebook community.
- Continued to develop relationships with local media for additional media at no charge.

3.5.4 Conduct Annual Effectiveness Assessment

Effectiveness assessment is a fundamental component required for the development and implementation of a successful storm water program. In order to determine the effectiveness of the Public Outreach Program Element, a comprehensive assessment of the program data is conducted as part of the Annual Report. The results of this assessment are used to identify modifications that need to be made to the program. Each year the effectiveness assessment is reviewed and revised as necessary.

By conducting these assessments and modifying the Program Element as necessary, the Permittees ensure that the iterative process is used as an effective management tool. Due to the types of data collected for the Public Outreach Program, current and future assessments will primarily focus on Outcome Levels 1, 2, and 3.

- Outcome Level 1 (L1) answers the question: Did the Permittees implement the components of the Permit?
- Outcome Level 2 (L2) answers the question: Can the Permittees demonstrate that the control measure/performance standard significantly increased the awareness of its target audience?
- Outcome Level 3 (L3) answers the question: Can the Permittees demonstrate that the control measure/performance standard changed a target audience's behavior, resulting in the implementation of recommended BMPs?

The following is an assessment regarding the effectiveness of the Public Outreach Program.

PO1 – Public Reporting

The Permittees have identified staff to serve as contact persons for public reporting. **(L1)**

The Permittees maintain two types of public reporting hotlines, one for general stormwater information and the other for reporting water pollution problems. **(L1)**

The Permittees are promoting and publicizing the public reporting hotlines and contact information. The information is available on Permittee web sites and is published in the government pages of the local phone book and other appropriate locations. **(L1)**

The Permittees are raising awareness about the public reporting hotline numbers. **(L2)**

PO2 – Public Outreach Implementation

The Permittees have developed and are implementing the public outreach program that provides key stormwater messages. **(L1)**

- Education of Ethnic Communities – The Permittees have developed and implemented a strategy to educate ethnic communities through culturally effective methods. The Permittees educated ethnic communities by reaching out to the Hispanic community in Ventura County via Spanish language advertising in the media. In 2011/12, Spanish language advertising accounted for approximately 15% of the annual media impressions.

- Storm Drain Inlet Markers and Signage – The Permittees have labeled or marked 99.7% of the storm drain inlets for the entire storm drain system and maintain the stencils/markers through the Public Agency Activities Program. In addition, 100% of all public access points to creeks and channels have signage with language that discourages illegal dumping, this includes access points that are outside of Permittee jurisdiction.
- Educational Materials – The Permittees have developed and are providing a variety of stormwater pollution prevention outreach materials, including those for specific pollutants and activities. The materials include pamphlets, brochures, and BMP posters. These are provided via a number of mechanisms, including at community events, at specific businesses, utility billing inserts, and the Countywide stormwater Web site (cleanwatershed.org/). In the 2010/11 permit year, the Permittees met the Permit requirement by distributing pollutant-specific outreach materials to the following business types: automotive parts stores; home improvement centers, lumber yards, and hardware stores; and pet shops and feed stores. In addition, the Permittees distributed activity-specific stormwater pollution prevention educational materials to residents regarding the following activities: proper disposal of litter, green waste, and pet waste; proper vehicle maintenance; lawn care; and water conservation practices.
- Mixed Media Campaigns – The Countywide program has continued to work with a local public relations agency, the Agency, to develop and implement Community for a Clean Watershed campaigns. The Permittees have provided the public with various stormwater-related articles or messages via radio and public access cable channel PSAs, movie theater slides, print ads (including newspaper), signage on outdoor bulletins and at transit shelters, and Web site banners. During 2011-2012, the Permittees conducted a total of three campaigns (Green Waste and Youth, and Trash) for an estimated 7.39 million total impressions through mixed media campaigns.
- Countywide Stormwater Web Site – The Permittees continue to maintain and utilize both Web sites (cleanwatershed.org/ and vcstormwater.org/) to provide regularly updated outreach to the public.
- Community Events – The Permittees outreached to the general public by sponsoring, organizing, and/or exhibiting at multiple community events and providing information to event attendees. These events included Coastal Cleanup Day; a total of 3,167 volunteers collected trash at 24 sites countywide.
- Pollutant-Specific Outreach – The Permittees are implementing a pollutant-specific outreach program rotating through metals, urban pesticides, bacteria, and nutrients in coordination with multi-media campaigns and retail partnerships with auto shops, pet stores, and home improvement stores and nurseries. Pollutant-specific outreach materials have been distributed via these retail partnerships.

As a result of the above efforts, in 2011/12, an estimated total of 7.39 million impressions were made, well exceeding the goal of five million stormwater quality impressions per year.

PO3 – Youth Outreach and Education

The Program's efforts towards youth continued to build on last year's outreach when a specific plan was created to reach 50% of all Ventura County school children (K-12) once every two years to comply with the NPDES Permit #CAS004002. With less than 150,000 school aged children enrolled in Ventura County schools, this translates to reaching approximately 75,000 in that target group every two years. While that goal was met and exceeded during the last Permit year with over 700,000 media impressions made on kids 6-11 and teens, the Program continues to speak to this important audience with a targeted media plan and a creative strategy that appeals to youth. Television, radio, and mall posters garnered 904,090 impressions – thus reaching this audience with significant repetition. In addition, the Facebook

page has a sizeable percentage of young fans (58%), allowing for a consistent message to be delivered to youth. This year the Program launched a new in-school youth outreach campaign with Q104.7-FM radio on-air personalities who visited 26 Ventura County middle and high schools in fall 2011. (L1)

PO4 – Business Outreach

The Permittees provided on-site consultation to businesses during inspections regarding their responsibility to reduce discharge of pollutants. Inspectors are also available for consultation via telephone and e-mail. (L1)

The Permittees distributed educational materials to specific businesses during inspections, when business licenses are obtained, and when problematic businesses are reported. In addition, information is made available on the Countywide Web site, and businesses are referred to the Web site as appropriate. (L1)

PO5 – Effectiveness Assessment

The Ventura County Watershed Permittees are committed to tracking performance of their outreach efforts. To that end, periodic research surveys are conducted to measure awareness, perceptions and actions taken by Ventura County residents to protect the local Watershed. The research also gives insight into whether outreach messaging is effective, along with providing some insight into local media preferences.

In order to establish a baseline of both our adult and K-12 target audiences' understanding of the watershed and surrounding stormwater pollution web surveys are routinely conducted.

The research results indicate a clear connection between key outreach messages and increases in understanding and shifts in behavior/attitude. This supports continued use of new and traditional media to educate youth on watershed protection.

The results outlined above show that the Public Outreach program efforts have increased awareness among Ventura County residents regarding some key issues impacting the health of Ventura County's watersheds. (L2) (L3)

3.5.5 Public Outreach Program Element Modifications

On an annual basis, the Permittees plan to evaluate the results of the Annual Report, as well as the experience that staff has had in implementing the program, to determine if any additional program modifications are necessary to comply with the Clean Water Act requirement to reduce the discharge of pollutants to the maximum extent practicable. Any key modifications made to the Public Outreach Program Element during the next fiscal year will be reported in the following Annual Report.

4 Industrial/Commercial Facilities Programs

4.1 OVERVIEW

The purpose of the Industrial/Commercial Facilities Program Element is to effectively prohibit unauthorized non-stormwater discharges and reduce pollutants in stormwater runoff from industrial and commercial facilities to the maximum extent practicable (MEP).

The daily activities of many businesses create a potential for pollutants to enter a storm drain system through both intentional and unintentional actions. The Permittees have developed programs to address this source of pollutants through inspections of targeted businesses and by providing educational outreach and enforcement if needed. These efforts include information on the potential for illicit discharges and illegal connections from businesses, assistance in the selection and use of proper BMPs, and may result in formal enforcement action and fines if environmental rules are ignored.

The program for industrial and commercial facilities is accomplished by tracking, inspecting, and ensuring compliance at industrial and commercial facilities identified as critical sources of pollutants in stormwater. Industrial and commercial facilities are managed under a single Program Element due to the similarities among these types of facilities and the effort involved to implement the program.

The Permittees use the Business Outreach and Illicit Discharge/Illegal Connection Subcommittee meeting to coordinate and implement a comprehensive program to control pollutants in stormwater discharges to municipal systems from targeted commercial facilities. The Subcommittee is comprised of representatives of the Permittee cities and other municipal staff from various departments (e.g. Environmental Health, Environmental Services, and Wastewater Services). The subcommittee provides an opportunity for the Permittees to learn from each other's experiences and develop and share resources. Each Permittee has implemented an Industrial/Commercial Business Program using the control measures identified below.

4.2 CONTROL MEASURES

Several Control Measures and accompanying performance standards have been developed by the Permittees to ensure that the Industrial/Commercial Facilities Program requirements found in the Permit are met and provide information for optimizing the Program. At the end of this chapter these control measures are evaluated to determine the effectiveness of this program element.

The Industrial/Commercial Facilities Program Control Measures are organized to be parallel to the organization of the Permit and consist of the following:

Table 4-1 Control Measures for the Industrial/Commercial Facilities Program Element

IC	Control Measure
IC1	Facility Inventory
IC2	Inspection
IC3	Industrial/Commercial BMP Implementation
IC4	Enforcement
IC5	Training
IC6	Effectiveness Assessment

4.3 FACILITY INVENTORY – IC1

The Facility Inventory Control Measure addresses the need to develop and maintain a complete and comprehensive database of industrial and commercial facilities that are determined to be critical sources of stormwater pollution. Information for the database is primarily derived from new business licenses and sanitary sewer connection permits. Facility inspections performed by the Permittees also continues to provide the details needed for the database. Some Permittees perform surveys of the industrial zoned areas in their jurisdiction to help maintain their industrial facility inventory. This survey is usually associated with industrial waste pretreatment inspections required for agencies operating a wastewater collection system.

4.3.1 Maintain and Annually Update the Industrial and Commercial Facility Inventory

As required by the Permit the Permittees maintain an inventory of industrial and commercial facilities within their jurisdictions, including those covered under the state Industrial General Permit. This inventory identifies the type of business, the watershed it is located in, and inspections and enforcement action history.

The Permittees supplement their inventory by utilizing data from County Environmental Health to obtain current facility numbers prior to planned inspections. The Regional Water Board’s website also provides useful information for all Industrial General Permit holders and is used extensively for that program. These data were first compiled during the 2009/10 reporting period and will be updated on an ongoing basis as the next round of inspections discovers new facilities, as well as companies that are no longer in operation. Some businesses, such as restaurants, have a high turnover with new ones opening each year and many permanently closing their doors. Because of the continued turnover of businesses the Industrial and Commercial inventory can never be assumed to be 100% accurate, it is a snap shot in time and will be continually updated as information becomes available. The current development of inventory for 2011/12 is summarized in the following Tables.

Performance Standard 4-1

<i>Did the Co-permittees maintain and update the Industrial and Commercial Facility Inventory</i>			
	<i>Yes</i>	<i>No</i>	<i>N/A</i>
<i>Camarillo</i>	<input checked="" type="checkbox"/>		
<i>Ventura County</i>	<input checked="" type="checkbox"/>

Figure 4-1 Commercial/Industrial Facilities Inventory

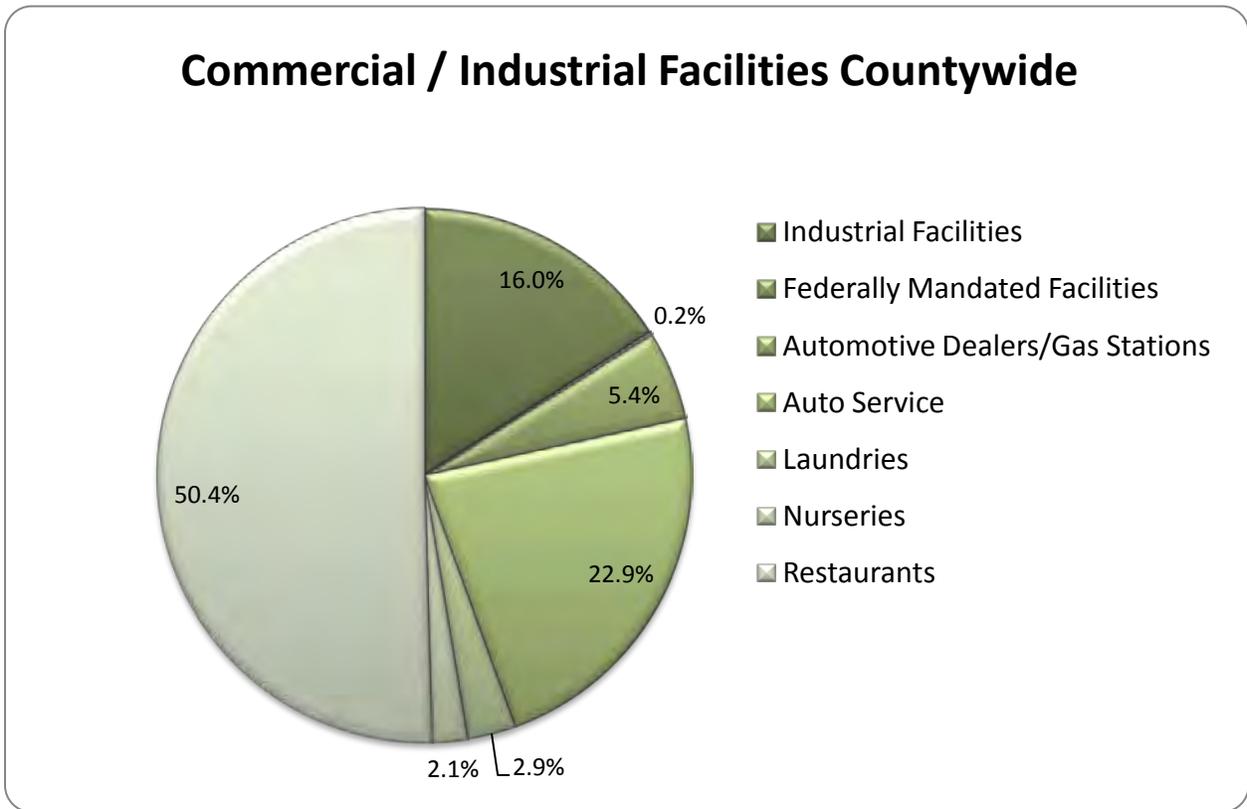

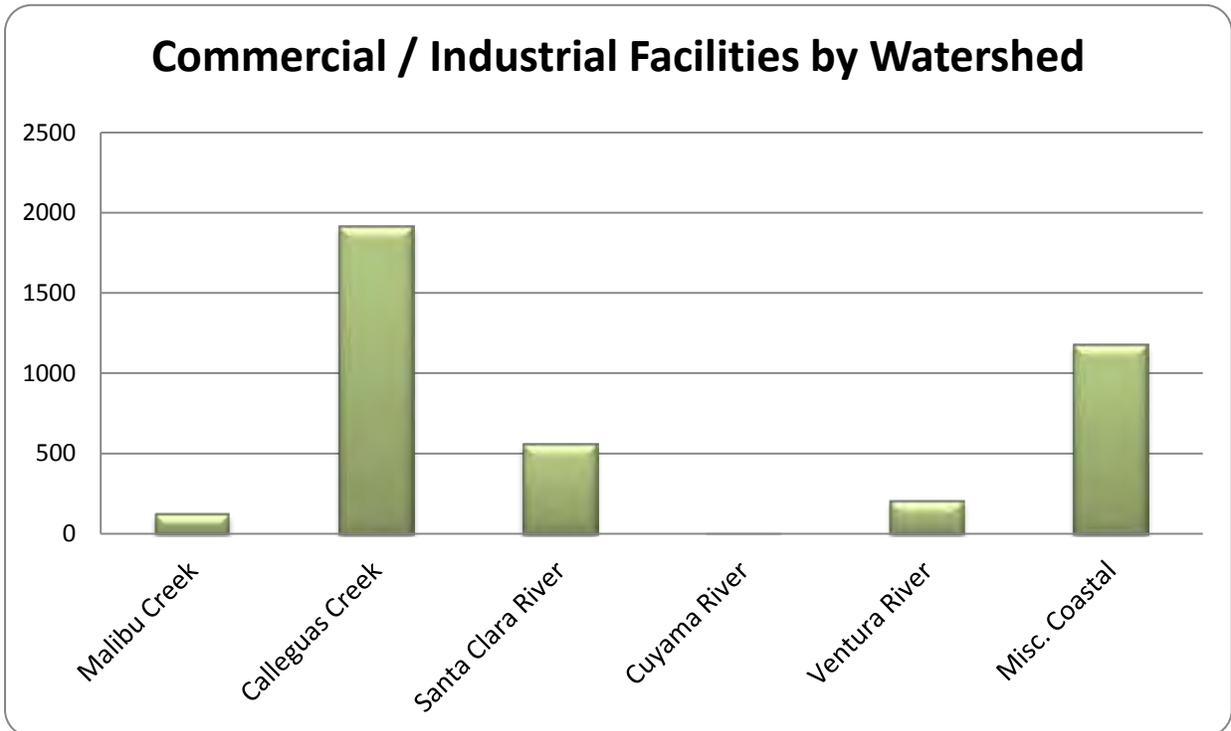

Figure 4-2 Commercial/Industrial Facilities by Permittee

Figure 4-3 Commercial Industrial Facilities by Watershed

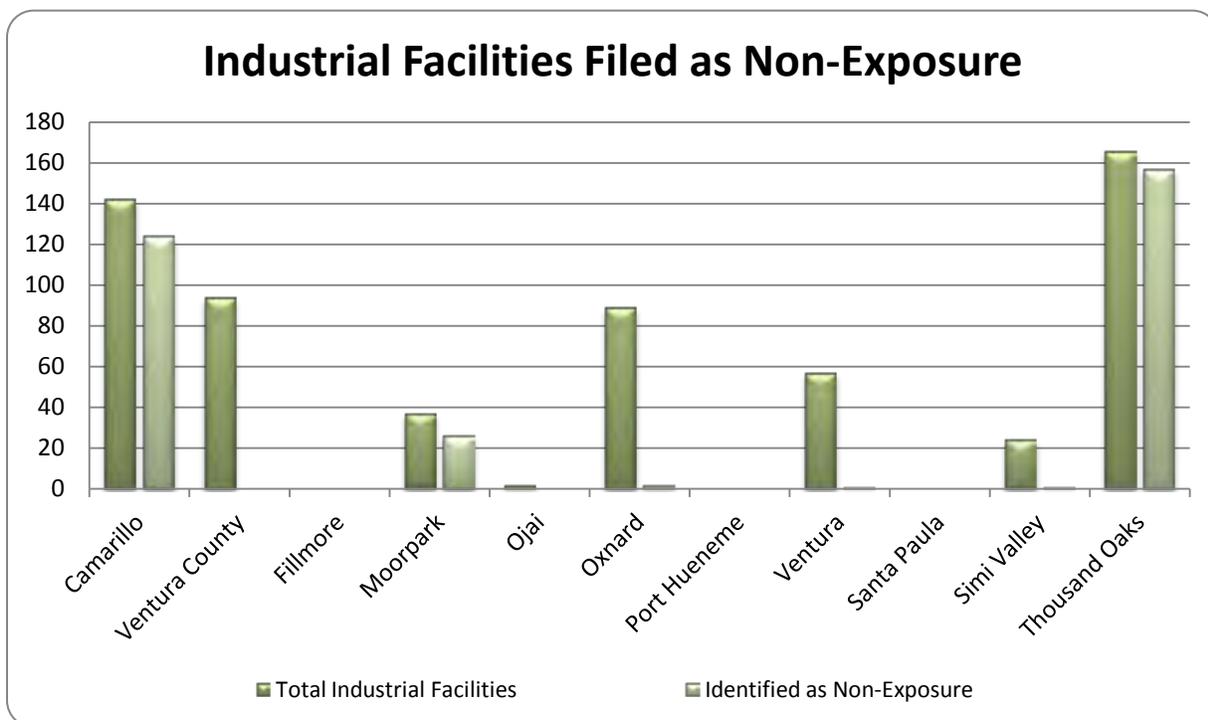

4.4 INSPECT INDUSTRIAL AND COMMERCIAL FACILITIES TWICE DURING PERMIT TERM

To satisfy the requirement of inspecting these facilities twice during the Permit term the Permittees began their inspection of industrial and commercial facilities in the 2009/10 Permit year. With respect to industrial facilities, if the initial inspection revealed no risk of exposure of industrial activities to stormwater at a facility, then that facility may be categorized as *No Exposure Status*. A second inspection is required at a rate that provides annual re-inspection of a minimum of 20% of all such facilities determined to have non-exposure.

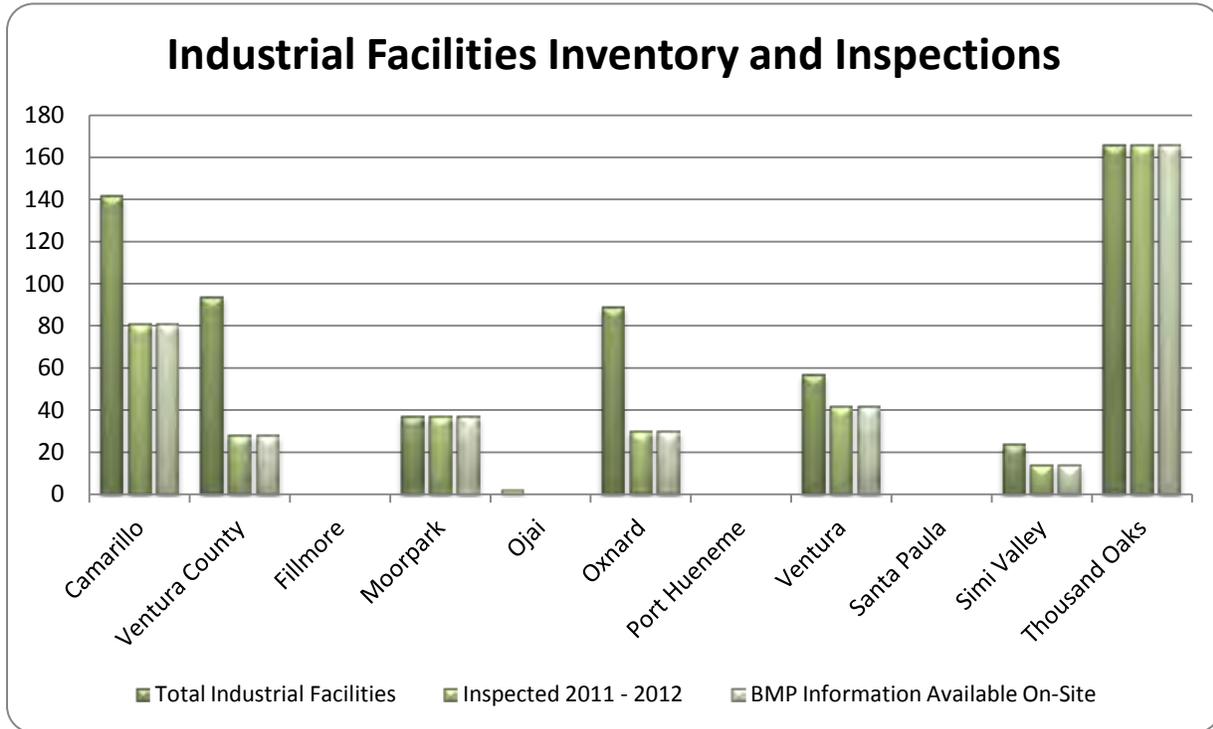

All initial industrial and commercial facility inspections must be completed no later than July 8, 2012. A minimum interval of six months between the first and second compliance inspection is required at all industrial and commercial facilities. It is possible that a site will be visited sooner than six months if requested by the Regional Board staff to assist with their investigations, or if an illicit discharge is suspected.

Figure 4-4 Industrial Facilities Filed as Non-Exposure

The permit requires the first industrial and commercial inspections be completed by July 8, 2012. The inspection programs are ongoing with continual updates to the inventory and facilities being re-inspected at least once more during the permit term. The status of the industrial commercial inspection program through the end of the reporting period is represented in the following tables.

Figure 4-5 Industrial Facilities Inventory and Inspections

Industrial Facilities includes U.S. EPA Phase I, II Facilities required to obtain coverage under the Industrial Activities Stormwater General Permit (IAGSP). These facilities are identified by either the Standard Industrial Classifications (SIC) or the North American Industry Classification System (NAICS). Facility ownership (federal, state, municipal, private) are not factors in this definition and so the inventory includes facilities such as the Naval Base Ventura County at Point Mugu.

**COUNTY OF VENTURA UNINCORPORATED AREA
STORMWATER MANAGEMENT PROGRAM**

**Stormwater Inspection Checklist
INDUSTRIAL AND FEDERALLY REGULATED FACILITIES**

INSPECTION TYPE

- INITIAL INSPECTION (see 07/01/2012)
- 1st Follow-up after INITIAL INSPECTION
- 2nd Follow-up after INITIAL INSPECTION
- 2nd Inspection of facilities with Exposure (6 months after INITIAL INSPECTION and not later than 07/01/2015)
- 1st Follow-up after 2nd inspection of facilities with Exposure
- 2nd Follow-up after 2nd inspection of facilities with Exposure
- 2nd Inspection of NON-EXPOSURE FACILITIES (minimum 20% annual)
- Complaint Response

FACILITY'S NAICS CODE: _____

FACILITY CATEGORY: _____

THIS FACILITY IS COVERED UNDER:

- Industrial Activities Stormwater General Permit (IAGSP) WQD # _____
- Is SWPPP available on the site? YES / NO
- Other Permit. Specify: _____
- No Exposure Certification, Notice of Non-applicability, No Discharge
- SWQCS Approval Letter received on: _____
- None

FACILITY IS LOCATED BY ONE OF THE FOLLOWING WATERSHEDS:

- Calleguas Creek
- Fillmore Creek
- Santa Clara River
- Ventura River
- Cuyama River
- Mac Coastal

A. Brief Description of Facility Operations:		Yes	No	N/A
Does this facility discharge to MGAs that directly discharge to CGAs or SDQS listed watersheds?				
If YES, make a note if BMPs are sufficient to maintain good SWP				
List potential problems, used and status of resources to determine:				
Describe activities that may contribute to pollution site runoff:				
BMP	B. Stormwater Management Criteria	Yes	No	N/A
DCS	Does the facility have stormwater discharges and controls being implemented to allow stormwater to be managed on-site?			

Page 1 of 2

Industrial facilities inspection form

Figure 4-6 Federally Mandated Facilities Inventory and Inspections

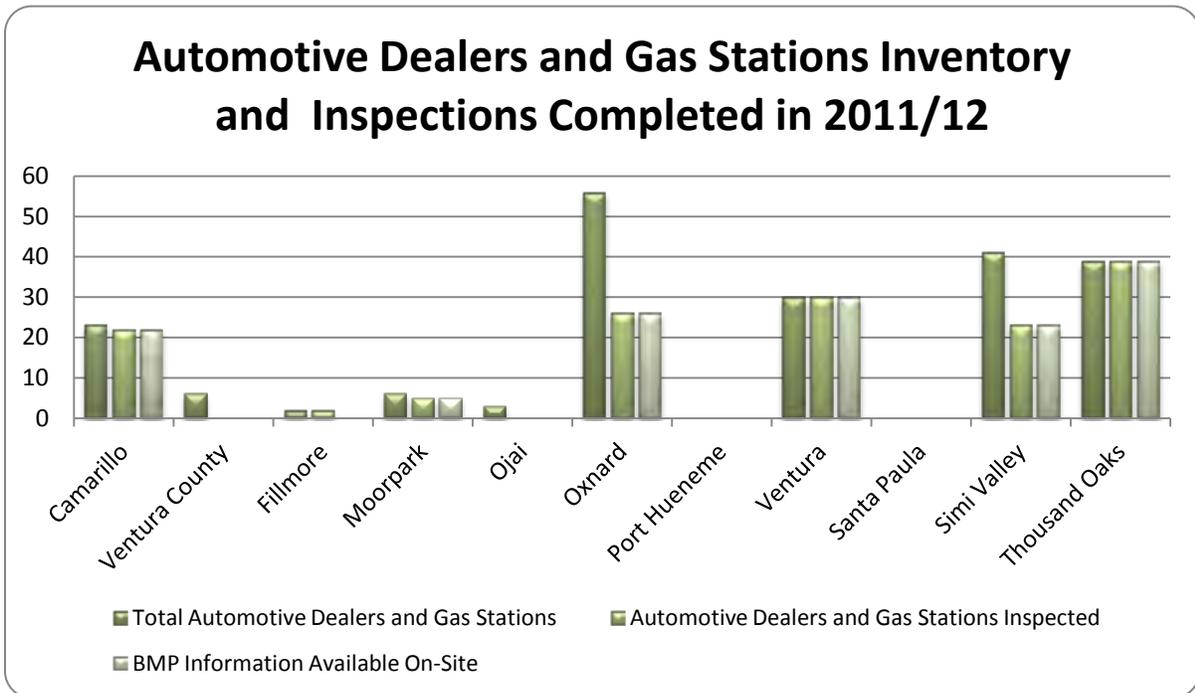

Other Federally-mandated Facilities [as specified in 40 CFR 122.26(d)(2)(iv)(C)] are also required to obtain coverage under the IAGSP. Again, facility ownership (federal, state, municipal, private) and profit motive (business or not-for-profit) of the facility are not factors in this definition. Included in this category are:

- Municipal landfills
- Hazardous waste treatment, disposal, and recovery facilities
- Facilities subject to SARA Title III (also known as the Emergency Planning and Community Right-to-Know Act (EPCRA))

Inspections are conducted at all automotive and gas station facilities even if these facilities do not have outdoor activities or storage that are exposed to stormwater. In addition, the Permittees have identified other facilities where engine oil is present and represents a potential threat to stormwater pollution, e.g., boat dealers, RV dealers, motorcycle dealers, etc. Facilities that are only inspected if they have outdoor activities or outside storage that are exposed to stormwater are auto parts stores and tire dealers.

Figure 4-7 Automotive Dealers and Gas Stations Inventory and Inspections

An inspector reviews the findings of an inspection with the business manager

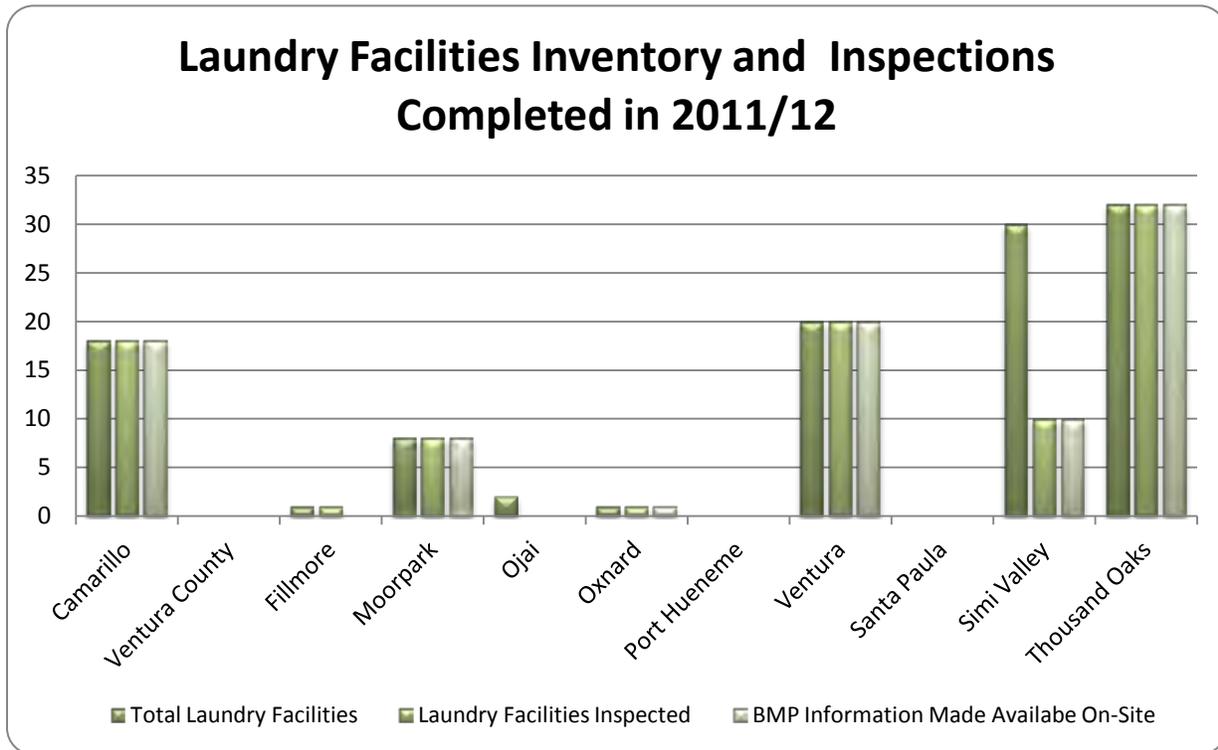

Figure 4-8 Automotive Service Facilities Inventory and Inspections

All automotive service facilities are included in the inventory for inspection, this category also includes motorcycle and boat repair if there is a potential for stormwater pollution.

Figure 4-9 Laundry Facilities Inventory and Inspections

Permittees made an effort to identify all laundry facilities in their jurisdiction that may possibly have an exposure to stormwater and therefore a possible threat to stormwater quality. Some Permittees went as far as to include dry cleaners and laundromats. All commercial laundries in a jurisdiction were identified and screened for potential exposure. If there was no exposure potential then an inspection was deemed unnecessary.

The Permit includes requirements for the Permittees to confirm that nursery operators that are exposed to stormwater implement pollutant reduction and control measures with the objective of reducing pollutants in stormwater runoff discharges. “Nurseries” comprises establishments primarily engaged in the merchant wholesale distribution of flowers, florists' supplies, and/ or nursery stock (except plant seeds and plant bulbs). The industry in NAICS Code 444220 comprises establishments primarily engaged in retailing nursery and garden products, such as trees, shrubs, plants, seeds, bulbs, floriculture products and sod, which are predominantly grown elsewhere. These establishments may sell a limited amount of a product they grow themselves.

This is interpreted by the Permittees to not include stores that may have some plants or a small nursery section although it is not their primary business. Florist that specialize in cut flowers are also not included because their business and inventory is kept indoors. However, most Permittees have extended this to include the large home improvement centers due to the size of their nursery section.

Figure 4-10 Nursery Facilities Inventory and Inspections

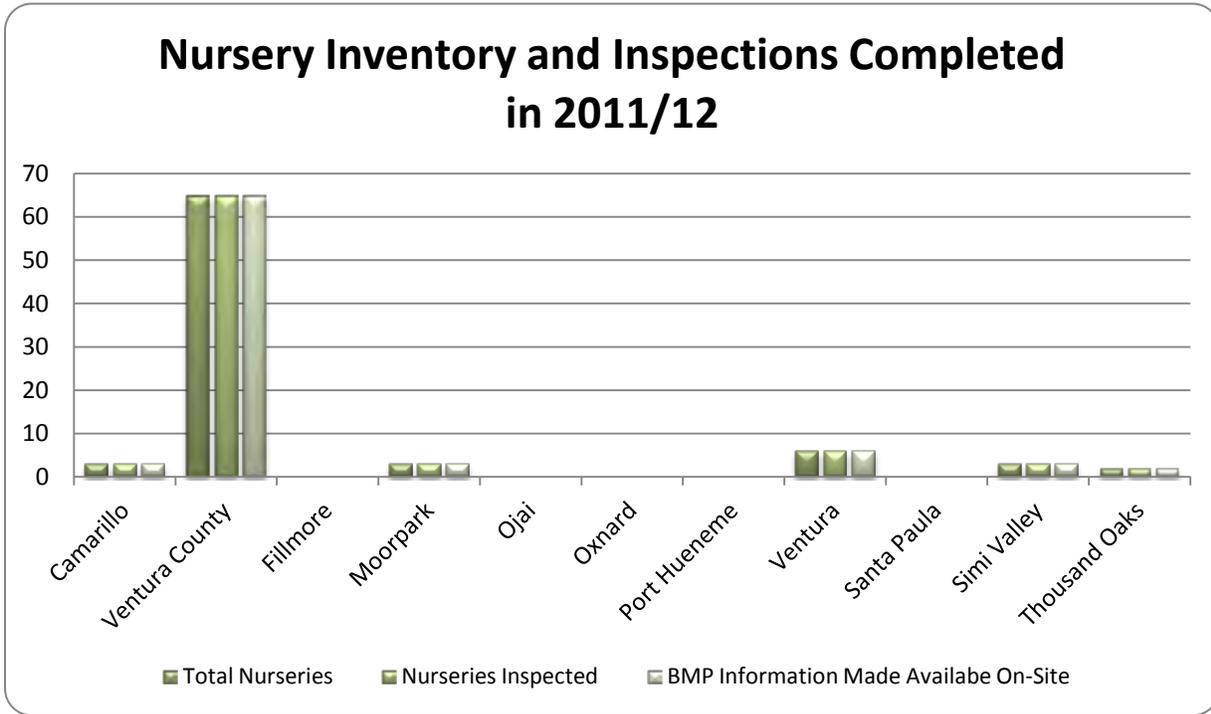

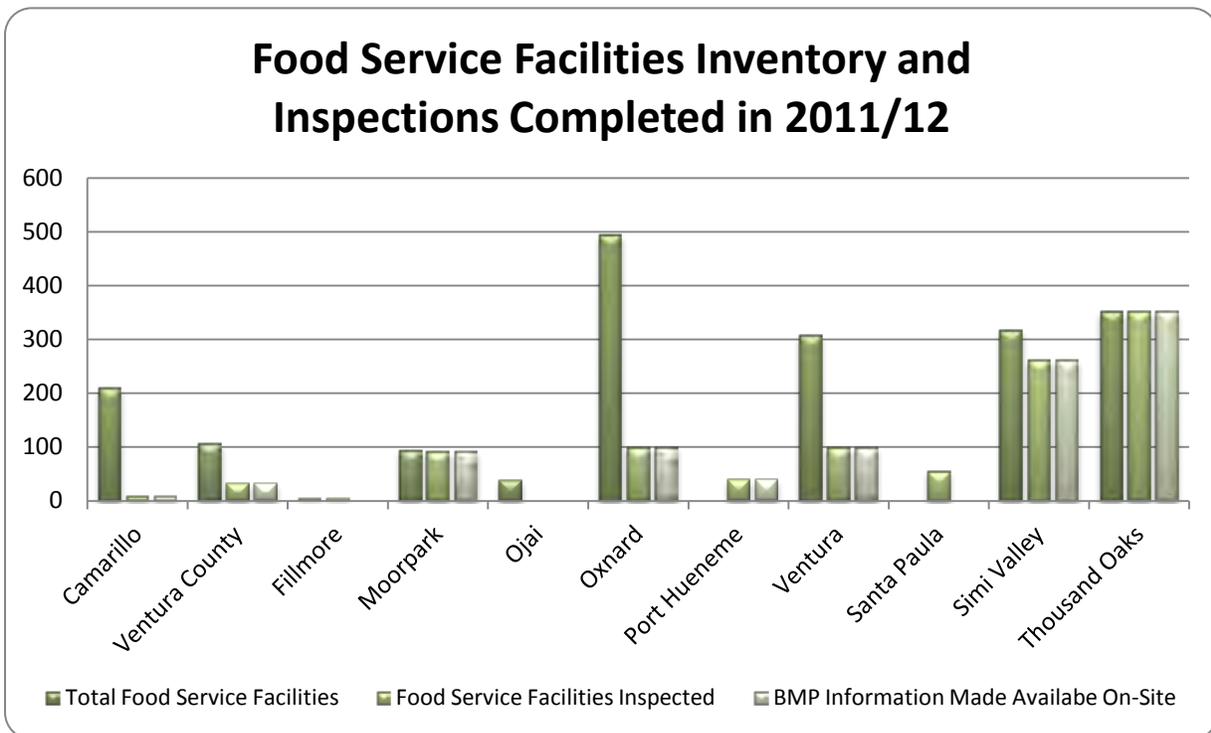

Figure 4-11 Food Service Facilities Inventory and Inspections

For the purposes of inventory and inspection the term food service facility means a facility that sells prepared foods and drinks for consumption, including stationary lunch counters and refreshment stands selling prepared foods and drinks for immediate consumption (SIC Code 5812). This will include supermarkets if they have a deli selling food which is prepared on-site, but will not include grocery stores, bakeries and candy stores not engaged in food preparation.

4.5 INSPECTION – IC2

The Inspection Control Measure establishes the inspection requirements associated with on-site visits. The inspections ensure that the facility operator is effectively implementing source control BMPs, is in compliance with municipal ordinances, has pertinent educational materials, and is not producing unauthorized non-stormwater discharges. Inspection of facilities covered under the IASGP also ensures that the operator has a current Waste Discharge Identification (WDID) number, a Stormwater Pollution Prevention Plan (SWPPP) is available on site, and the operator is effectively implementing BMPs. Stopping unauthorized discharges is the primary purpose of the inspections, however it is also just as important to educate businesses on proper disposal of wastes and other BMPs to prevent future discharges to the storm drain system. To accomplish this educational information is made available to businesses that do not immediately have it available for their staff.

4.5.1 Inspections

The Permittees’ municipal ordinances currently allow authorized officers to enter any property or building to perform inspections. On refusal to allow inspection by the owner, tenant, occupant, agent or other responsible party, the Permittees may seek an Administrative Search Warrant. All the Permittees have or are reviewing their ordinances to determine if there is a need to strengthen their ability to perform inspections, as well as the enforcement tools at their disposal to bring an uncooperative business into compliance.

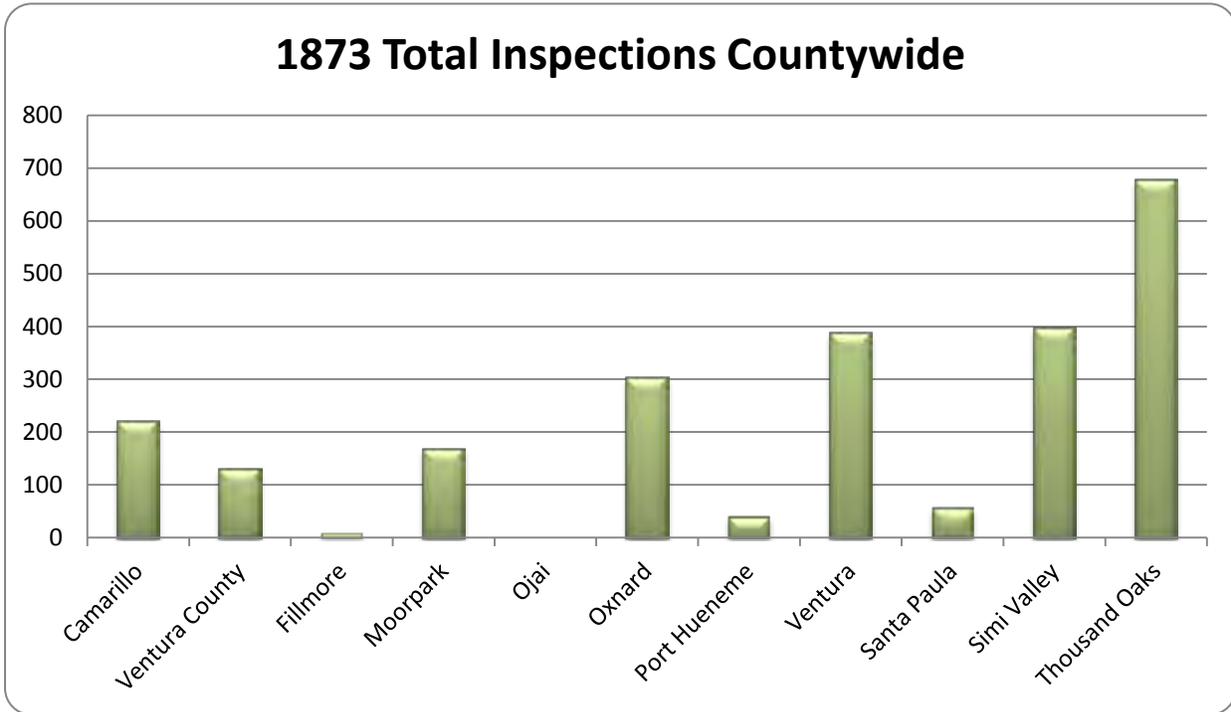

Performance Standard 4-2

<i>Begin initial inspections of commercial and industrial facilities? (inspections to be completed by July 8, 2012)</i>			
	<i>Yes</i>	<i>No</i>	<i>N/A</i>
<i>Camarillo</i>	<input checked="" type="checkbox"/>		
<i>Ventura County</i>	<input checked="" type="checkbox"/>		
<i>Fillmore</i>	<input checked="" type="checkbox"/>		
<i>Moorpark</i>	<input checked="" type="checkbox"/>		
<i>Ojai</i>	<input checked="" type="checkbox"/>

<i>Santa Paula</i>		<input checked="" type="checkbox"/>	
<i>Simi Valley</i>	<input checked="" type="checkbox"/>		
<i>Thousand Oaks</i>	<input checked="" type="checkbox"/>		

The vast majority of site visits performed were unannounced providing the inspectors with an honest look at daily activities of the facility. During these site visits, Permittee inspection staff would meet with the business owner/manager to review the objectives of the inspection. After performing a walk-through of the facility, inspection results were discussed with the business owner/manager. In the event a Permittee determined a facility’s stormwater BMPs were insufficient, the Permittee provided their recommendations to the facility owner/manager. Source control BMPs were recommended as a first step in BMP implementation before requiring the facility to implement costly structural BMPs. In all cases,

inspection staff informed facilities’ owners/managers that BMP implementation does not guarantee compliance nor relieve them from additional regulations, and that it is their continued responsibility to ensure that pollutants do not escape the facility.

Figure 4-12 Total Inspections Countywide

Review/Revise the Industrial Inspection and Commercial Business-Specific Checklists as Needed

In order to ensure that the inspectors conduct thorough and consistent inspections, industrial and commercial checklists have been developed for different targeted businesses. Permittee industrial inspectors receive proper training to adequately assess facilities and offer assistance in suggesting remedies. County and municipal ordinances with support from City Attorney’s and County Counsel offices also provide the proper legal backing for inspections and any necessary enforcement. Checklists are periodically updated as necessary to ensure that they provide an adequate and sufficiently comprehensive basis upon which to conduct inspections. Currently, the Program has inspection checklists for general industry, restaurants, automobile related businesses, nurseries, and laundries. Examples of the checklists are included as Attachment A.

Conduct Follow-up Inspections as Necessary

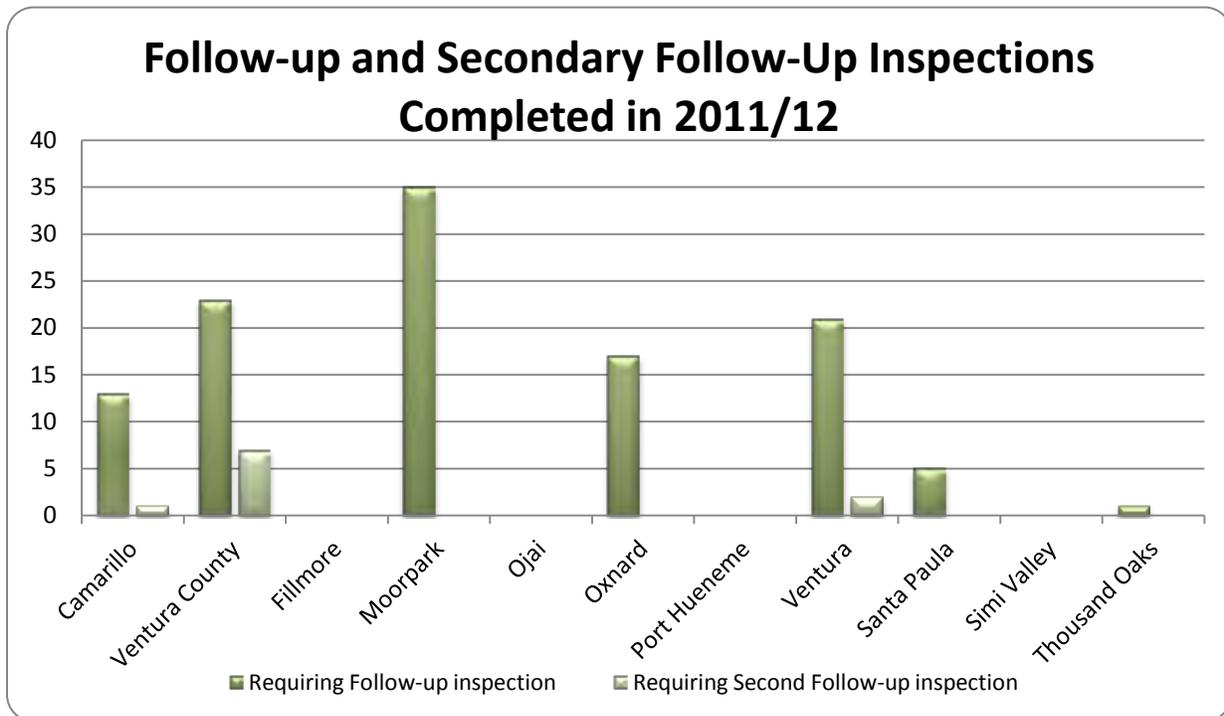

Whenever the Permittee determined that an operator had failed to adequately implement all necessary BMPs as required by the Permit, or otherwise were deemed out of compliance, the Permittee engaged in progressive enforcement action. If the facility can be brought into compliance while the inspector is still on-site a follow-up inspection is not deemed necessary. All other facilities that failed to implement all necessary BMPs were advised there would be follow-up visits. The Permit requires that re-inspection occurs within four weeks of the initial inspection. Follow-up visits may be scheduled, especially if the facility operator is difficult to get a hold of, but for the majority of businesses the follow-up inspections are unannounced surprise inspections. If continued stormwater violations were found progressive enforcement actions were initiated, and another visit was scheduled if necessary. Enforcement actions may include any of the following: Warning Notice, Notice of Violation(s), Administrative Civil Liability actions and monetary fines. These actions are described in detail and reported in Section 8 - Programs for Illicit Discharges.

Performance Standard 4-5

<i>Conduct follow-up inspections as necessary</i>

Figure 4-13 Follow-up and Secondary Inspections

4.6 INDUSTRIAL/COMMERCIAL BMP IMPLEMENTATION – IC3

The Industrial/Commercial BMP Implementation Control Measure requires industrial and commercial businesses to reduce pollutants in stormwater discharges and cease any unauthorized non-stormwater discharges to the storm drain system. Although the Permittees may provide guidance to facility operators on appropriate Source and Treatment Control BMP selection and application, the selection of specific

BMPs to be implemented is the responsibility of the discharger. The Permittees develop business specific guidance (fact sheets) that is updated as necessary to reflect new requirements and/or knowledge.

4.6.1 BMP Fact Sheets and Selection

In order to assist the industrial and commercial facilities in selecting and implementing the appropriate types of BMPs, the Permittees developed BMP Fact Sheets for industrial and commercial businesses. The BMP Fact Sheets are distributed during the inspections and made available on the Ventura Countywide Stormwater Quality Management Program's website at the following address:

http://www.vcstormwater.org/programs_business.html#business_factsheets

BMP fact sheets were updated and new ones created for several target audiences during this reporting period including:

- Building and Grounds Maintenance
- Pool and Spa Maintenance
- Commercial Pesticide Application
- Mobile Cleaning Services
- Mobile Auto Detailing and Charity Car Wash Events, and
- Building Repair and Remodeling.

These have been added to the library of fact sheets the Program has already developed for automotive service facilities, RGOs, and nurseries.

4.6.2 Distribute BMP Fact Sheets during Inspections

The Permittees distribute BMP Fact Sheets to facility owners/operators as a part of the inspection process. The development and distribution of these fact sheets, along with the inspection program where inspectors meet with the local facility managers about stormwater regulations and BMPs also serves to meet the Permit requirement for Corporate Outreach under the Public Information and Participation Program.

<i>Thousand Oaks</i>	<input checked="" type="checkbox"/>		

4.7 ENFORCEMENT– IC4

The Enforcement Control Measure outlines the progressive levels of enforcement applied to industrial and commercial facilities that are out of compliance with County and municipal ordinances and establishes the protocol for referring apparent violations of facilities subject to the Industrial Activities Storm Water General Permit to the Regional Water Board. The Enforcement Control Measure has been developed to address specific legal authority issues related to industrial and commercial facility discharges and should be implemented in coordination with the Permittees’

efforts to maintain adequate legal authority for the Stormwater Program in general.

4.7.1 Implement the Progressive Enforcement and Referral Policy

The Permittees have a progressive enforcement and referral policy so that the enforcement actions match the severity of a violation and include distinct, progressive steps initiated to bring a facility into compliance. Options are available for progressive corrective actions for repeat offenders. Inspections are performed to assess compliance with municipal stormwater ordinances and any noncompliance is managed through the enforcement policy. Noncompliance may include failure to implement adequate source control or structural BMPs, or other violations of County and municipal ordinances.

The Permittees’ facility inventory contains an “inspection findings” data field for comments pertaining to the specific facility. If there is an unsatisfactory inspection, then a comment is made in this data field and the facility is marked for re-inspection within four weeks of the date of initial unsatisfactory inspection. Past experience with facilities has shown that facility operators are cooperative and willing to bring facilities into compliance.

Performance Standard 4-7

<i>Implement a progressive enforcement policy</i>			
	<i>Yes</i>	<i>No</i>	<i>N/A</i>
<i>Camarillo</i>	<input checked="" type="checkbox"/>		
<i>Ventura County</i>	<input checked="" type="checkbox"/>		
<i>Fillmore</i>	<input checked="" type="checkbox"/>		
<i>Moorpark</i>	<input checked="" type="checkbox"/>		
<i>Ojai</i>	<input checked="" type="checkbox"/>		
<i>Oxnard</i>	<input checked="" type="checkbox"/>		
<i>Port Hueneme</i>			<input checked="" type="checkbox"/>
<i>Ventura</i>	<input checked="" type="checkbox"/>		
<i>Santa Paula</i>		<input checked="" type="checkbox"/>	
<i>Simi Valley</i>	<input checked="" type="checkbox"/>		
<i>Thousand Oaks</i>	<input checked="" type="checkbox"/>		

Implementation of Referral Policy

As a means to enhance interagency coordination, the Permittees may refer industrial business violations of County and/or municipal stormwater ordinances and California Water Code §13260 to the Regional Water Board, provided that Permittees have made a good faith effort of progressive enforcement under applicable stormwater ordinances. Referral to the Regional Water Board is required so that they can enforce the conditions of their permit on non-compliant industries. Every effort is taken at the local level to achieve compliance before referring a facility, including using the threat of calling in the Regional Board and their ability to levy hefty fines. It is possible that the Regional Board would be notified immediately if very egregious problems were

discovered at a site covered by the Industrial Activities Stormwater General Permit (IASGP). At a minimum the permit requires Permittees provide a good faith effort to bring a facility into compliance, which must be documented with:

- Two follow-up inspections
- Two warning letters or notices of violation

For those facilities in violation of municipal ordinances and subject to the IASGP, the Permittees may escalate referral of such violations to the Regional Water Board after one inspection and one written notice (copied to the Regional Water Board) to the operator regarding the violation. This is up to the discretion of the Permittee, and is only likely to be used in cases where there is a severe discharge causing or contributing to a water quality exceedance.

Such referrals are filed electronically with the Regional Water Board for any inspection that led to a notice of violation or the discovery of a non-filer. In making such referrals, Permittees are required to include at a minimum the following information in their referral:

1. Name of facility
2. Operator of facility
3. Owner of facility
4. WDID number (if applicable)
5. Industrial activity being conducted at the facility that is subject to the IASGP
6. Records of communication with the facility operator regarding the violation, which shall include at least an inspection report
7. The written notice of the violation copied to the Regional Water Board

The Permittees were able to bring all IAGSP facilities into compliance, and none were referred to the Regional Board for further enforcement.

4.7.2 Investigation of Complaints Transmitted by Regional Water Board

On occasion, Regional Board staff will receive information on an industry within a Permittee's jurisdiction that needs to be investigated in a timely manner. The Permittees implement procedures for responding to complaints forwarded by the Regional Water Board to ensure initiation of inspections within one business day. Permittees may comply by taking initial steps (such as logging, prioritizing, and tasking) to "initiate" the investigation within one business day. However, the Regional Water Board expects that the initial investigation, including a site visit, would occur within four business days. Complaint-initiated inspections include, at a minimum, a limited inspection of the facility to confirm the complaint, to determine if the facility is effectively complying with municipal stormwater urban runoff ordinances and, if necessary, to initiate corrective action.

The Permittees have (and will continue to) work closely with the Regional Water Board when a facility is identified as requiring a compliance inspection. The Permittees were able to bring all facilities into compliance that were not immediately found to be in compliance.

Table 4-2 Complaints Transmitted by Regional Water Board for Investigation by Permittees

Facility Category	Nature of Complaint	Confirmation of Complaint	Permittee Assistance and/or Corrective Action
<i>Industrial</i>			
None			
<i>Other Federally-Mandated Facilities</i>			
None			

4.7.3 Task Force Participation

The Permittees will participate in an interagency workgroup, such as the Environmental Task Force or the Storm Water Task Force, as a means to communicate information and concerns regarding stormwater enforcement actions undertaken by the Permittees. Participation in such a workgroup should facilitate communication of special cases of stormwater violations and address a coordinated approach to enforcement action.

The Ventura County Stormwater Program and Permittees, including different divisions such as CUPA or County Environmental Health, participate on the Ventura County Environmental Crimes Task Force. This task force is led by the District Attorney’s office and includes representatives from different environmental agencies including the Ventura Air Pollution Control District, California EPA, and Federal EPA. The purpose is to work together to share sensitive information on enforcement activities to increase the chances of eliminating the problem.

4.8 TRAINING – IC5

The Training Control Measure is important for the implementation of the Industrial/Commercial Program Element. An effective training program is one of the best pollution prevention BMPs that can be implemented because it provides for consistency in inspections and enforcement, gives the inspector the ability to respond to a variety of situations and questions, and ultimately encourages the inspectors to initiate behavioral changes that are fundamentally necessary to protect water quality.

Each Permittee identified inspection staff and other personnel for training based on the type of stormwater quality management and pollution issues that they might encounter during the performance of their regular inspections or daily activities. Targeted staff may include those who perform inspection activities as part of the HAZMAT and wastewater pretreatment programs as well as staff who may respond to questions from the public or industrial/commercial businesses, such as those working with business licenses.

Staff was trained in a manner that provided adequate knowledge for effective business inspections, enforcement, and answering questions from the public or industrial/commercial operators. Training included a variety of forums, ranging from informal “tailgate” meetings, to formal classroom training and self-guided training methods. When appropriate, staff training included information about the prevention, detection and investigation of illicit connections and illegal discharges (IC/ID). See **Section 8** for more information regarding IC/ID training.

Performance Standard 4-8

Conduct training for key staff involved in the Business Inspection program

<ul style="list-style-type: none"> Industrial/Commercial inspectors County Health restaurant inspectors 	<ul style="list-style-type: none"> Classroom Field Demos 	<ul style="list-style-type: none"> Overview of stormwater management program Stormwater ordinance and enforcement policy BMPs for facilities Facility inventory tracking 	<ul style="list-style-type: none"> Training seminars or workshops related to the program may be made available by other organizations

Figure 4-14 IC/ID Training

4.9 EFFECTIVENESS ASSESSMENT – IC6

Effectiveness assessment is a fundamental component required for the development and implementation of a successful stormwater program. In order to determine the effectiveness of the Industrial/Commercial Facility Program Element, a comprehensive assessment of the program data is conducted as part of the Annual Report. The results of this assessment are used to identify modifications that need to be made to the Program Element. Each year the effectiveness assessment is reviewed and revised as necessary.

By conducting these assessments and modifying the Program Element as necessary, the Permittees ensure that the iterative process is used as an effective management tool. Due to the types of data collected for the Industrial/Commercial Facility Program, current and future assessments will primarily focus on Outcome Levels 1 and 2 though behavior changes can be seen as a reduction in discharges is observed and the need for enforcement drops.

- Outcome Level 1 (L1) answers the question: Did the Permittees implement the components of the Permit?
- Outcome Level 2 (L2) answers the question: Can the Permittees demonstrate that the control measure/performance standard significantly increased the awareness of its target audience?
- Outcome Level 3 (L3) answers the question: Can the Permittees demonstrate that the control measure/performance standard changed a target audience's behavior, resulting in the implementation of recommended BMPs?

The following is an assessment regarding the effectiveness of the Industrial/ Commercial Program.

4.9.1 Facility Inventory Maintain and Annual Update Inventory

All Permittees maintain an inventory of industrial and commercial facilities. Permittees have begun to inspect facilities with the goal of completing all initial inspections by July 8, 2012 and inspecting facilities twice during the permit term. Initially inspections focused on industrial facilities, auto dealers, auto service shops, laundry facilities, nurseries and restaurants. (L1)

4.9.2 Inspection

Initial inspections were performed by this reporting year. Some Permittees initiated inspections over the 2009-10 reporting periods and continued them through the 2011/12 period to meet this deadline. (L1) Permittees conducted 115 follow-up inspections as needed to ensure compliance. Since the Permit adoption over 5600 inspections were conducted Countywide (L2).

The Permittees have reviewed and revised their inspection checklists, as necessary to be consistent with the permit. (L1)

4.9.3 Industrial/Commercial BMP Implementation

BMP Fact Sheets and Selection

Industrial and commercial BMP Fact Sheets were developed and are available at the Ventura Countywide Stormwater Quality Management Program website. (L1)

Distribute BMP Fact Sheets

Permittees that have initiated an inspections program distribute fact sheets as part of the inspection process. (L1)

4.9.4 Enforcement

Implement Progress Enforcement and Referral Policy

The Permittees have a progressive enforcement and referral policy so that enforcement actions match the severity of a violation and include distinct, progressive steps introduced to bring a facility into compliance. (L1)

Implementation of Industrial Referral Policy

All Permittees may refer industrial business violations to the Regional Water Board provided that Permittees have made a good faith effort of progressive enforcement. (L1)

Investigation of Complaints Transmitted by Regional Water Board

The Permittees implement procedures for responding to complaints forwarded by the Regional Water Board to ensure initiation of inspections within one business day. (L1)

Task Force Participation

The Permittees will participate in an interagency workgroup, such as the Environmental Task Force or the Storm Water Task Force, as a means to communicate information and concerns regarding stormwater enforcement actions undertaken by the Permittees. (L1)

4.9.5 Training

During this reporting period, the Permittees trained 49 staff in business inspections and enforcement. Permittees effectively trained 94% of targeted staff. (L1)

4.9 INDUSTRIAL/COMMERCIAL PROGRAM ELEMENT MODIFICATIONS

On an ongoing basis, the Permittees evaluate the experience that staff has had in implementing the program and the results of the Annual Report to determine if any additional program modifications are necessary to comply with the Clean Water Act requirement to reduce the discharge of pollutants to the MEP.

Many key modifications have been made to the Industrial/Commercial Program Element with the adoption of the new permit. Key modifications that have been made are tracking facilities by watershed, an expanded list of businesses and industries that are tracked and clearly defining how to identify those businesses and industries. Future efforts may look into the inspections or outreach to the owners of multi-tenant commercial retail areas with common trash areas.

5 Planning and Land Development

5.1 OVERVIEW

The addition of impervious areas in the development of homes, industrial and commercial businesses, parking lots, and streets and roads increases the amount of stormwater runoff, as well as the potential for pollution. The Planning and Land Development Program Element ensures that the impacts on stormwater quality from new development and redevelopment are limited through implementation of general site design measures, site-specific source control measures, low impact development strategies, and treatment control measures. The general strategy for development is to avoid, minimize, and mitigate (in that order) the potential adverse impacts to stormwater. The potential for long-term stormwater impacts from development is also controlled by requiring ongoing operation and maintenance of post-construction treatment controls.

The Permittees have developed and implemented a Program for Planning and Land Development to address stormwater quality in the planning and design of development and redevelopment projects. The term “development project” as used in this Program encompasses those projects subject to a planning and permitting review/process by a Permittee. A development project includes any construction, rehabilitation, redevelopment or reconstruction of any public and private residential project, industrial, commercial, retail, and other non-residential projects, including qualifying public agency projects.

To help meet the goals and objectives of the Program, the Permittees attend Planning and Land Development Subcommittee meetings to coordinate and implement a comprehensive and consistent program to mitigate impacts on water quality from development projects to the maximum extent practicable (MEP). However, the Permittees may modify their programs to address particular issues, concerns or unique constraints to a watershed such as local geology or known water quality impairments.

5.2 CONTROL MEASURES

The Permittees have developed several Control Measures and accompanying performance standards to ensure that the planning and land development program requirements are effectively developed and implemented. For each Control Measure there are accompanying performance standards which, once accomplished, constitute compliance with the Permit requirements. The Planning and Land Development Program Control Measures consists of the following:

Table 5-1 Control Measures for the Planning and Land Development Program Element

LD	Control Measure
LD1	State Statute Conformity
LD2	New Development/ Redevelopment Performance Criteria
LD3	Plan Review and Approval Process
LD4	Maintenance Agreement and Transfer
LD5	Tracking, Inspection and Enforcement
LD6	Training
LD7	Effectiveness Assessment

5.3 STATE STATUTE CONFORMITY – LD1

Traditional methods of land development can lead to increased stormwater discharge volumes and flow velocities. These alterations to the natural hydrologic regime may reduce infiltration to groundwater, and increase erosion and flooding and decrease habitat integrity. Water quality and watershed protection principles and policies such as minimization of impervious areas, pollutant source controls, preservation of natural areas, and peak runoff controls can help to minimize the impacts of urban development on the local hydrology and aquatic environment. Integration of stormwater quality and watershed principles into the Permittees' general conditions will serve as the basis for directing future planning and development in order to minimize these adverse effects. In addition, the California Environmental Quality Act (CEQA) process provides for consideration of water quality impacts and appropriate mitigation measures.

5.3.1 Review/Revise CEQA Review Documents

The California Environmental Quality Act (CEQA) sets forth requirements for the processing and environmental review of many projects. The Permittees use the CEQA process and review as an excellent opportunity to address stormwater quality issues related to proposed projects early in the planning stages. The National Environmental Quality Act (NEPA) comes into play less often than CEQA, but may be included on projects involving federal funding. Like CEQA, NEPA process and review provides opportunities to address stormwater quality issues related to proposed projects early in the planning stages.

The CEQA review process is necessary for determining what impacts a proposed development project could have on the environment. The Permittees' current CEQA review process includes procedures for considering potential stormwater quality impacts and providing for appropriate mitigation. Permittees will review and revise the CEQA review documents as needed for consistency with the new Permit.

Each Permittee has reviewed their internal planning procedures for preparing and reviewing CEQA (and NEPA when applicable) documents and has linked stormwater quality mitigation conditions to legal discretionary project approvals. When appropriate, the Permittees consider stormwater quality issues when processing environmental checklists, initial studies, and environmental impact reports. The Permit requires that stormwater controls are incorporated into the Permittees CEQA process by July 8, 2011; the Permittees have been successful in meeting that obligation.

5.3.2 Revise the General Plan

The Permittees' General Plans provide the foundation and the framework for land use planning and development. Therefore, the General Plan is a useful tool to promote the policies for protection of stormwater quality. The Permittees are to include watershed and stormwater management considerations in the appropriate elements of their General Plans whenever these elements are significantly rewritten. Table 5-2 indicates the scheduled date of a significant rewrite to the Permittees' General Plan elements if known. Note that some Permittees have already modified their General Plan to include stormwater requirements under the previous permit, the table reflects if stormwater issues have been incorporated. The Permit additionally requires that when General Plan elements are being updated drafts are provided to the Regional Board for their review. These permit requirements do not have an absolute due date other than as General Plan elements are updated. The 2011 Ventura County General Plan was updated for the 2020 horizon year, and the Housing Element is scheduled for additional updates by October 2013; submittal of the updated Housing Element to Regional Board hasn't been scheduled yet. The Oxnard City

Council adopted the 2030 General Plan on October 11, 2011; this plan is available for review at cityofoxnard.org.

5.4 NEW DEVELOPMENT PERFORMANCE CRITERIA – LD2

Post-construction BMPs, including site design, source control, low impact development techniques, and stormwater quality treatment, are necessary for development and re-development projects to mitigate potential water quality impacts. In addition, priority projects identified within the Permit require specific mitigation measures. In order to assist developers in meeting these requirements, the Permittees developed a Technical Guidance Manual for Stormwater Quality Control Measures for new development and redevelopment in 2002 (TGM 2002). This Manual was updated to conform with the new Permit requirements in 2011 (2011 TGM) these requirements became effective during the reporting period.

5.4.1 Update to the 2002 Ventura County Technical Guidance Manual for Stormwater Quality Control Measures (TGM)

In May 2010 the Permittees updated the 2002 TGM for the selection, design, and maintenance of BMPs for new development and redevelopment projects as identified in Order 2009-0057. This Manual was never approved by the Regional Board Executive Officer due to the permit being remanded and subsequently re-heard by the Board. As an outcome of that hearing new language was adopted for the Permit and a new date set for the revisions to TGM. The TGM was rewritten to address the five-percent effective impervious area requirement, retention and biotreatment, alternative compliance for technical infeasibility, interim hydro-modification requirements, water quality criteria, and maintenance agreements (see also Control Measure LD4 for more information). The 2011 TGM was submitted to the Regional Board on June 16, 2011. The regional approved the 2011 TGM on July 13, 2011 and it became effective on October 11, 2011.

Low Impact Development BMP

5.4.2 Require Compliance with Performance Criteria

New development and redevelopment projects, as outlined in Permit Provision 4.E.II., are subject to Permittee conditioning and approval for the design and implementation of post-construction controls to mitigate stormwater pollution. New performance criteria outlined within the Permit include reducing the percentage of effective impervious area to five-percent or less of the total project area, hydromodification control criteria, and water quality mitigation criteria. These Permit conditions became effective 90 days after the TGM was approved by the Regional Board Executive Officer.

Project Review and Conditioning

For projects whose applications were deemed complete prior to the 2011 TGM effective date the Permittees are to ensure they comply with the previous performance criteria under the Stormwater Quality Urban Impact Mitigation Plan (SQUIMP)

and the 2002 TGM. Under both manuals the Permittees' approach to stormwater comes early in the project development process when the options for pollution control are greatest, and the cost to

incorporate these controls into new development or redevelopment projects is the least. In planning and reviewing a development project, the Permittees consider three key questions with respect to stormwater quality control: 1. what kind of water quality controls are needed? 2. where should controls be implemented? 3. what level of control is appropriate? During the planning and review process, the Permittees identify potential stormwater quality problems, communicate design objectives, and evaluate the plan for the most appropriate design alternatives.

Stormwater Quality Urban Impact Mitigation Plan (SQUIMP)

For those projects deemed complete before October 11, 2011 the Permittees require the implementation of the Stormwater Quality Urban Impact Mitigation Plan (SQUIMP) for new development projects that fall into one or more of the following categories:

- Single-family hillside residences;
- 100,000 square foot commercial development;
- Automotive repair shops;
- Retail gasoline outlets;
- Restaurants;
- Home subdivisions with 10 or more housing units;
- Locations within, or directly adjacent to or discharging to an identified Environmentally Sensitive Area (ESA); or
- Parking lots of 5,000 square feet or more with 25 or more parking spaces and potentially exposed to stormwater runoff.

In addition, redevelopment projects in one of the SQUIMP categories that result in the creation, addition or replacement of 5,000 square feet or more of impervious surfaces, that is not a part of routine maintenance, are subject to SQUIMP requirements. If a redevelopment project creates or adds 50% or more impervious surface area to the existing impervious surfaces, then stormwater runoff from the entire area (existing and redeveloped) must be conditioned for stormwater quality mitigation. Otherwise, only the affected area of the redevelopment project requires mitigation.

The SQUIMP lists the minimum required BMPs that must be implemented for new development and redevelopment projects subject to the SQUIMP. The minimum requirements include the following BMPs:

- Control peak stormwater runoff discharge rates
- Conserve natural areas
- Minimize stormwater pollutants of concern
- Protect slopes and channels
- Provide storm drain stenciling and signage
- Properly design outdoor material storage areas
- Properly design trash storage areas
- Provide proof of ongoing BMP maintenance
- Meet design standards for structural or treatment control BMPs
- Comply with specific provisions applicable to individual priority project categories, which include the following: 100,000 square foot commercial development; restaurants; retail gasoline outlets; automotive repair shops; and parking lots.

Santa Paula	<input checked="" type="checkbox"/>		
Simi Valley	<input checked="" type="checkbox"/>		
Thousand Oaks	<input checked="" type="checkbox"/>		

5.4.3 BMP Selection and Design Criteria

The Permittees consider site-specific conditions of development projects and pollutants of concern on the watershed when determining which BMPs are most appropriate for a site. Prior to approving BMPs, the staff conditioning the project evaluates post-construction activities and potential sources of stormwater pollutants. The project proponent is required to consider BMPs that would address the potential pollutants reasonably expected to be present at the site once occupied. BMPs to protect stormwater during the construction phase may also be a part of this conditioning process, although these are addressed through the grading permit process through the Construction Program

Low Impact Development BMP

In order to achieve appropriate stormwater quality controls, the Permittees use the following common criteria in screening and selecting, or rejecting BMPs during the planning stage with a priority given to non-proprietary designed BMPs:

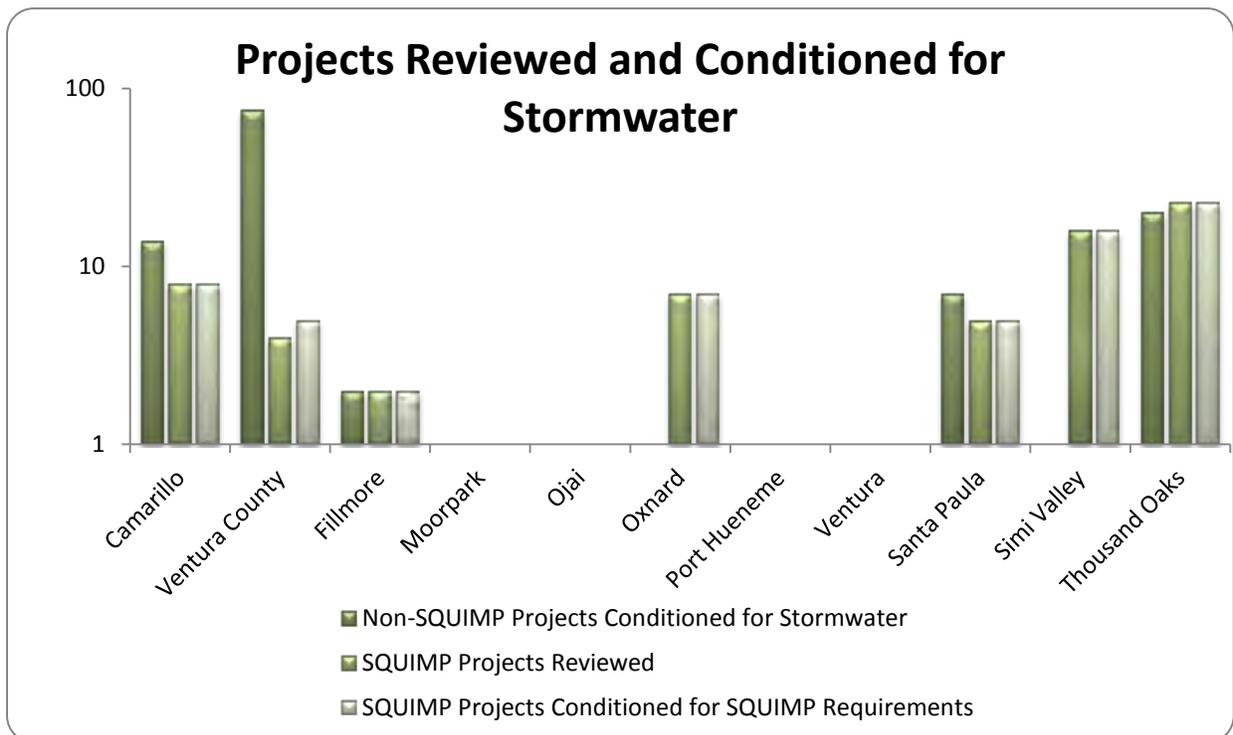

- Project characteristics;
- Site factors (e.g., slope, high water table, soils, etc.);

- Pollutant removal capability;
- Short term and long term costs;
- Responsibility for maintenance;
- Contributing watershed area; and
- Environmental impact and enhancement.

The BMP selection criteria listed above is applied by the Permittees in accordance with the overall objective of the Planning and Land Development Program, i.e. to reduce pollutants in discharges to the MEP. In some site-specific situations there will be BMPs clearly be more appropriate and effective than others, the BMP selection process reflects this variability.

The number of projects required to comply with the performance criteria during the permit year is outlined in Figure 5-1. This includes projects required by the Permit to implement stormwater treatment controls, but beyond that projects that due to their nature or potential to discharge pollutants of concern, were also required to implement stormwater management controls of either source control or water quality treatment.

Figure 5-1 Projects Reviewed and Conditioned

5.4.1 Potential of Offsite Mitigation Projects

The new requirements of the Permit allow an alternative to compliance with the land development criteria of onsite retention and biotreatment for projects with technical infeasibilities through the use of offsite mitigation. New developments and significant re-developments that have identified technical infeasibilities, and therefore cannot comply with the retention and biofiltration requirements onsite have the option of utilizing alternative mitigation offsite.

The Permittees are in the process of developing an offsite mitigation framework and identifying potential locations. Infill and redevelopment projects that demonstrate technical infeasibility may be eligible for offsite mitigation. As required by the Permit, Permittees will provide a list of offsite opportunities and track and summarize offsite mitigation projects.

The Permittees researched potential management and funding structures for creating a new offsite stormwater alternative mitigation program as identified in the Permit. The project focused on general funding mechanisms, accounting, and the program management structure needed to implement and sustain a long term stormwater retention and/or biofiltration program. The second prong of the project focused on potential locations for the offsite program using an integrated water resources approach. The first step was to determine the potential need for offsite mitigation to understand the scale of projects that may be needed.

Because development projects are required to manage as much water on site as possible the final results of the projected needs assessment yielded a volume of only eight acre feet countywide would need to be managed offsite by 2030. This volume of water is not a significant amount and did not attract the potential for integrated water resource management programs with third party partners (e.g. local water agencies) to support the development of offsite BMPs. From these studies the Permittees learned that the offsite need for any one project is likely to be small enough to be manageable in the public right-of-way of the permitting agency and maintained through conventional funding mechanisms.

5.4.2 Require Hydromodification Criteria

Permittees currently require the interim hydromodification criteria as specified in Permit provision 4.E.III.3(a)(3). Interim criteria will be required until the Southern California Water Monitoring Coalition (SMC) completes the Hydromodification Control Study (HCS).

The purpose of Hydromodification Control Measures is to minimize impacts to natural creeks due to changes in postdevelopment stormwater runoff discharge rates, velocities, and durations by maintaining, within a certain tolerance, the project's pre-project stormwater runoff flow rates and durations.

Hydromodification Control Measures may include onsite, subregional, or regional Hydromodification Control Measures; Retention BMPs; or stream restoration measures. Preference will likely be given to onsite Retention BMPs and Hydromodification Control Measures; however in-stream restoration measures may be determined to be the best use of resources and may more effectively and quickly address the beneficial uses of natural drainage systems.

The Southern California Stormwater Monitoring Coalition (SMC) is developing a regional methodology to eliminate or mitigate the adverse impacts of hydromodification as a result of urbanization, including

hydromodification assessment and management tools. The Program will develop and implement watershed specific Hydromodification Control Plans (HCPs) after the completion of the SMC study (Permit requires HCP is submitted 180 days after the completion of the SMC study). Until the completion of the HCPs, the Interim Hydromodification Control Criteria, described below, apply to applicable, non-exempt new development and redevelopment projects.

Performance Standard 5-3

Participate in the Stormwater Monitoring Committee's Hydromodification Control Study			
	Yes	No	N/A

Performance Standard 5-4

Develop and implement watershed specific HCPs? (180 days after the completion of the SMC HCS)			
	Yes	No	In Progress
Ventura Countywide Stormwater Quality Program			<input checked="" type="checkbox"/>

The Permit states that “Permittees may exempt projects from implementation of hydromodification controls where assessments of downstream channel conditions and proposed discharge hydrology indicate that adverse Hydromodification effects to present and future beneficial uses of Natural Drainage Systems are unlikely: Projects that discharge directly or via a storm drain into concrete or improved (not natural) channels (e.g., rip rap, sackcrete, etc.)” Because of the emphasis on natural drainage systems, defined by the permit as “not engineered” the Permittees have undertaken a mapping exercise to identify all the improved, or engineered, rivers and channels where the Permit identified hydromodification exemptions apply. This map can then be used to identify the rivers and channels where hydromodification will need to be considered by new and redevelopment.

5.4.3 Interim Hydromodification Control Criteria

Interim hydromodification controls for projects deemed complete after the effective date which disturb less than 50 acres shall be complying with the stormwater management standards contained in the 2011 TGM.

Projects disturbing 50 acres or greater must develop and implement a Hydromodification Analysis Study (HAS) that demonstrates that post development conditions are expected to approximate the pre-project erosive effect of sediment transporting flows in receiving waters. The HAS must lead to the incorporation of project design features intended to approximate, to the extent feasible, an Erosion Potential value of 1, or any alternative value that can be shown to be protective of the natural drainage systems from erosion,

incision, and sedimentation that can occur as a result of flow increases from impervious surfaces and damage stream habitat in natural drainage systems.

5.5 PLAN REVIEW AND APPROVAL PROCESS

Stormwater quality controls should be considered throughout the development plan review and approval process. Comprehensive review by the Permittees of development plans must be provided in order to ensure that stormwater controls minimize stormwater quality impacts.

5.5.1 Conduct BMP Review

Permittees conducted a detailed review of site designs and the proposed BMPs. Review included matching BMPs to the pollutants of concern, sizing calculations, pollutant removal performance and municipal approval. Project designs are not approved unless all conditions have been met.

Performance Standard 5-5

318 rain barrels were sold this year through the Program's co-operative effort with the County's Integrated Waste Management Division, over 1400 sold since Permit adoption.

5.5.2 Establish Authority among Municipal Departments with Project Review Jurisdiction

Permittees have an established structure for communication and delineated authority between municipal departments that have jurisdiction over project review, plan approval, and project construction. Each Permittee has approached this in the manner that will be most effective within their organization. Interdepartmental communication and coordination does not represent a complicated hurdle for the smaller agencies, however, larger agencies such as the County of Ventura have formally drafted Memorandums of Understanding to establish the structure and define responsibilities.

5.6 TRACKING, INSPECTION AND ENFORCEMENT – LD4

Permittees have implemented a tracking systems and an inspection and enforcement program for new development and redevelopment post-construction stormwater BMPs.

Figure 5-2 Publicly and Privately Maintained BMPs

5.6.1 **Develop/Implement a Tracking System for Post-Construction Treatment Control BMPs**

Permittees have been conditioning development projects for stormwater controls since the 2002 TGM and understand that maintenance of these BMPs is instrumental to their performance of improving water quality. Developing and implementing a system for tracking projects that have been conditioned for post-construction treatment control BMPs is necessary to ensure that BMPs are properly maintained and working. The Permit requires this tracking system be in place by July 8, 2011.

Each Permittees' electronic system should contain the following information:

1. Municipal Project ID
2. State WDID No.(IAGSP)
3. Project Acreage
4. BMP Type and Description
5. BMP Location (coordinates)
6. Date of Acceptance
7. Date of Maintenance Agreement
8. Maintenance Records
9. Inspection Date and Summary
10. Corrective Action
11. Date Certificate of Occupancy Issued
12. Replacement or Repair Date

5.6.2 **Conduct Inspections of Completed Projects**

Beginning July 8, 2011 the Permittees are required to conduct inspections of completed projects subject to the Planning and Land Development Program requirements to ensure proper installation of all approved control measures have been implemented and are being maintained. Identifying and tracking these projects will follow the development permitting process. The Certificate of Occupancy is withheld until a project can show that BMPs have been installed as designed on approved plans. See Attachment B for an example inspection checklist from the City of Camarillo.

Performance Standard 5-7

Develop and implement a system for tracking projects that have been conditioned for post-construction treatment control BMPs? (by July 8, 2012)

Simi Valley	<input checked="" type="checkbox"/>		
Thousand Oaks	<input checked="" type="checkbox"/>		

5.6.3 Conduct Inspections of Permittee Owned BMPs

The Permittees are responsible for the inspection and maintenance of BMPs they own and operate. Sometimes Permittees will accept this responsibility from a development as a way to ensure that proper maintenance is performed. Not all Permittees own and operate BMPs, and some have not yet installed or accepted ownership of permanent BMPs. These inspections are required once every two years. The first inspection was due July 8, 2012, which is outside the reporting period of this report.

Figure 5-3 Permittee Operated BMPs

Thousand Oaks	<input checked="" type="checkbox"/>			

5.6.4 Require Annual Reports for Post-Construction BMPs

In July of 2011 the Permittees were required to require the submittal of Annual Reports for BMPs maintained by parties other than the Permittees. The annual reports are to provide information to the Permittees showing that the BMPs have been properly maintained. In many cases a copy of an invoice from a service provider showing the date maintenance performed will suffice for an annual report.

Figure 5-4 BMP Annual Reports

Performance Standard 5-10

Ventura	<input checked="" type="checkbox"/>		
Santa Paula	<input checked="" type="checkbox"/>		
Simi Valley	<input checked="" type="checkbox"/>		
Thousand Oaks	<input checked="" type="checkbox"/>		

5.7 Take Enforcement Action

Inspections and the requirement for annual reports are only the first steps towards ensuring BMPs are operational. Enforcement actions based on the results of the inspection may be needed in order to bring the facility into compliance. The Permit requires inspections of Permittee owned BMPs and enforcement is not necessary in that scenario. To ease future compliance the Permittees are performing educational outreach to the owner/operators of BMPs.

A performance standard on enforcement may be developed in future reports, however, enforcement would only be needed when there is non-compliance. Low enforcement numbers (high level of compliance) may represent an effective program just as well as high enforcement numbers would represent a determined effort to return BMPs to compliance.

5.8 MAINTENANCE AGREEMENT AND TRANSFER – LD5

Maintenance agreement and transfers ensure that post-construction BMPs will remain effective upon project completion and continued occupancy. As a condition of approval for all priority development projects, Permittees require the owner/ developer/successor-in-interest of stormwater BMPs to provide proof of control measure maintenance in the form of a Stormwater Treatment Device Operation and Maintenance Agreement and a Maintenance Plan.

5.8.1 **Require Stormwater Treatment Device Operation and Maintenance Agreement**

Permittees integrated the development/submittal of a stormwater maintenance agreement as a condition within the project approval process for projects subject to the Permit's Planning and Land Development Program requirements. To enforce the requirements of post-construction BMPs, a Maintenance Agreement is required to be executed between the Permittee and the owner/developer/successor-in-interest for any private facilities who remain the responsible party in operating and maintaining the post-construction Treatment Control Measures.

The 2002 TGM and the 2011 TGM revisions address the development and submittal of Maintenance Agreements when a developer is responsible for ongoing maintenance of onsite treatment BMPs.

5.9 TRAINING – LD6

Training is important to the successful implementation of the Planning and Land Development Program Element. An effective training program is one of the best pollution prevention BMPs that can be implemented because this subject is complicated and requires many interpretations and judgment calls.

To facilitate the implementation of the new Technical Guidance Manual a special training session was held in June of 2011. This training was open to private sector developers as well as the planners and plan check engineers who will be interpreting and implementing the new standards. It was important to have everybody in the same room receiving the same training to minimize confusion and conflict at the counter when actual projects will be coming in for approval. This six-hour training was attended by well over one hundred people.

5.10 EFFECTIVENESS ASSESSMENT – LD7

Effectiveness assessment is a fundamental component for developing and implementing successful stormwater programs. In order to determine the effectiveness of the Planning and Land Development Program, a comprehensive assessment of the program data is conducted as a part of the annual report. The results of this assessment are used to identify modifications that need to be made to the program. Each year the effectiveness assessment is reviewed and revised as needed.

By conducting these assessments and modifying the program as needed, the Permittees ensure that the iterative process is used as an effective management tool. Due to the types of data collected for the Planning and Land Development Program, current and future assessments will primarily focus on Outcome Levels 1, 2 & 3.

- Outcome Level 1 (L1) answers the question: Did the Permittees implement the components of the Permit?
- Outcome Level 2 (L2) answers the question: Can the Permittees demonstrate that the control measure/performance standard increased awareness of a target audience?
- Outcome Level 3 (L3) answers the question: Can the Permittees demonstrate that the control measure/performance standard changed a target audience’s behavior, resulting in the implementation of recommended BMPs?

The following is an assessment regarding the effectiveness of the Planning and Land Development Program.

5.10.1 State Statute Conformity

Review/Revise CEQA Review Documents

The CEQA process and plan review process is an effective mechanism for addressing stormwater quality issues early in the planning stages. Where applicable, all Permittees have reviewed their internal planning procedures for preparing and reviewing CEQA documents. All Permittees have formally integrated stormwater quality issues into the CEQA review process (**L1**).

Revise the General Plan

The majority of Permittees have either already incorporated or are in the process of incorporating stormwater requirements into their General Plans (**L1**). This control measure is dependent on the scheduled updates/amendments to General Plans which varies greatly by municipality. Once updated,

Permittees will submit draft elements to the Regional Board for review. Effectiveness of this control measure will continue to be evaluated as progress is made.

5.10.2 **New Development Performance Criteria**

Update the 2002 Ventura County TGM

The 2002 Ventura County TGM was updated and submitted to the Regional Board on June 16, 2011 (L1). The updated TGM (2011 TGM) includes:

- Interim hydromodification criteria (addressed in Section 2);
- Expected BMP pollutant removal performance (addressed in Section 3 and Appendix D);
- Improved correlation of BMPs with stormwater POCs (addressed in Section 3 and Appendix D);
- BMP maintenance and cost considerations (addressed in Section 7, Appendices H & I);
- Integration of integrated water resources planning and management goals (Sections 1 and 4).

Require Compliance with Performance Criteria

Permittees continued to require compliance with 2002 TGM for all SQUIMP new development and redevelopment project categories (L1). As indicated in Figure 5-1, Permittees reviewed 465 projects and required 66 projects to implement source control and/or water quality treatment (note these numbers apply to both SQUIMP and non-SQUIMP project categories) (L2). The 2011 TGM became effective October 11, 2011, 90 days after its approval by the Regional Board Executive Officer. With the 2011 TGM in effect, priority new development and redevelopment project will be required to comply with the 5% EIA Requirement and other new development provisions contained within Order No. R4-2010-0108.

Documentation of Offsite Mitigation Projects

The Permittees are in the process of developing an offsite mitigation framework and creating a list of potential locations.

Require Hydromodification Criteria

The Permittees currently require SQUIMP project categories to comply with the interim hydromodification criteria (L1). The Ventura Countywide Stormwater Quality Program continues to participate in the SMC's hydromodification control study (L1). Permittees will implement watershed-specific HCP's once the hydromodification control study is complete.

5.10.3 **Plan Review and Approval Process**

Conduct BMP Review

Proposed post-construction BMPs were reviewed by each of the Permittees. BMP review included calculation sizing and pollutant removal performance. Permittees have effectively conducted BMP review for several years now and current review mechanisms are considered adequate (L1).

Establish Authority among Municipal Departments

Each Permittee has successfully established the authority for review of stormwater quality measures. The mechanism varies by Permittee and for the larger Permittees may consist of a formal MOU (L1).

5.10.4 Tracking, Inspection and Enforcement

Develop/Implement Tracking Mechanism

Permittees have been conditioning development projects for stormwater controls since the last permit and understand that maintenance of these BMPs is instrumental to their performance of improving water quality. Developing and implementing a system for tracking projects that have been conditioned for post-construction treatment control BMPs is necessary to ensure that BMPs are properly maintained and working. (L1)

Conduct Inspections of Completed Projects

This performance measure was due July 8, 2011 and all 11 Permittees have conducted inspections of completed projects to ensure they were done in accordance with the land development requirements, or do not have completed projects and are in the process of developing their inspections programs (L1) (L2).

Conduct Inspections of Permittee Owned BMPs

Eight of the Permittees are already inspecting the BMPs they own and operate, while others have not built or adopted BMPs. (L1)

Take Enforcement Action

Four of the Permittees have needed to take enforcement action to ensure proper BMP maintenance - five others reported that enforcement actions were not necessary to achieve compliance. This performance measure is reliant on the implementation of an inspection program which was not required to be fully implemented during this reporting period. (L2)

5.10.5 Maintenance Agreement and Transfer

Require Stormwater Treatment Device Access and Maintenance Agreement

Permittees have required since 2002 and will continue to require a maintenance agreement to ensure proper maintenance and permission to enter property and access BMPs (L1).

Require Annual Reports for Post-Construction BMPs

All Permittees reported that they have required annual reports or are in the process of generating the reporting procedures with the intention of having it operational by the July 2012 due date (outside of this reporting period).

5.10.6 Training

Conduct Training

During this reporting period, Permittees trained 88 staff. Training primarily focused on updates to the 2011 TGM (L1).

5.11 PLANNING AND LAND DEVELOPMENT PROGRAM MODIFICATIONS

On an annual basis, the Permittees plan to evaluate the results of the Annual Report, as well as the experience that staff has had in implementing the program, to determine if any additional program

modifications are necessary to comply with the Clean Water Act requirement to reduce the discharge of pollutants to the MEP. Any key modifications made to the Land Development Program Element during the next fiscal year will be reported in the following Annual Report, such as the implementation of the new requirements that became effective during the 2011/12 Permit year.

6 Development Construction

6.1 OVERVIEW

During construction projects, a number of activities have the potential to generate or mobilize pollutants. The purpose of the Development Construction Program Element is to coordinate programs and resources to effectively reduce pollutants in runoff from construction sites during all construction phases.

Reducing pollutants from construction activities has been a focus of the Permittees' compliance program since the stormwater program's inception. The Permittees regulate private construction activities, and also have responsibility for the construction and renovation of municipal facilities and infrastructure (these projects are reported in Section 7 Public Agency Activities). Major components of the Permittee's Construction Program include:

- Review of local SWPPPs for compliance with local codes, ordinances, and permits;
- Inspection of all construction sites for the implementation of stormwater quality controls a minimum of once during the wet season. Follow-up inspections take place within two weeks for sites found to have not adequately implemented their Local SWPPP;
- Require proof of filing a Notice of Intent (NOI) for coverage under the State General Construction Permit prior to issuing a grading permit for all projects requiring coverage.

Additionally, the Construction Program provides construction site owners, developers, contractors, and other responsible parties information on the requirements and guidelines for pollution prevention/BMP methods. To ensure construction sites are implementing the SWPPPs properly, each jurisdiction conducts inspections during the rainy season to verify the appropriateness and implementation of BMPs, taking enforcement action as necessary. Inspectors are also visiting the sites in the dry season to ensure the potential for illicit discharges has been reduced. Training and outreach is done regularly to improve the quality and consistency of program implementation throughout Ventura County.

The Permittees attend the Construction Subcommittee meetings to coordinate and implement a comprehensive program to mitigate impacts on water quality from construction sites to the maximum extent practicable (MEP). In order to facilitate effective inspections and to document compliance with this requirement the Construction Subcommittee developed a model Stormwater Quality Checklist for Permittee use, which can be found in Attachment C. The checklist and the meetings create countywide consistency in the programs, however, the Permittees usually modify their programs to address particular issues, concerns, or constraints that are unique to a particular watershed or to an individual municipality. The Subcommittee is attended by representatives of the Permittee's cities and other municipal staff from various departments including Engineering Services, Planning and Land Development, and Inspection Services.

6.2 CONTROL MEASURES

The Permittees have developed several Control Measures and accompanying performance standards to provide information for optimizing the program and ensure that the construction-related requirements in the Permit are met. For each Control Measure there are accompanying performance standards which, once accomplished, constitute compliance with the Permit.

The Development Construction Program Control Measures consist of the following:

DC	Control Measure
DC1	Plan Review and Approval Process
DC2	Inventory
DC3	Inspections and BMP Implementation
DC4	Enforcement
DC5	Training
DC6	Effectiveness Assessment

Table 6-1 Control Measures for the Development Construction Program Element

At the end of this chapter these control measures are evaluated to determine the effectiveness of this program element.

6.3 PLAN REVIEW AND APPROVAL PROCESS – DC1

The Plan Review and Approval Process control measure provides the Permittees with the mechanism to review and approve construction plans which address sediment and erosion controls. Effective planning of construction site activities leads to minimizing erosion and preventing pollutants from entering the storm drain system. The Permittees require all projects that disturb less than one acre of land to address pollutants and activities during the construction phase of the project by implementing the erosion control, sediment control, non-stormwater management, and waste management BMPs identified in the NPDES Permit. For larger projects greater than one acre, and less than five acres, the list of required BMPs gets progressively larger, more complex, and more protective. Prior to issuing a grading permit, the Permittees review construction and grading drawings to ensure that necessary erosion and sediment control BMPs and source and treatment control BMPs are identified and properly designed to control runoff pollution to the MEP. In the case of construction that encroaches in the Watershed Protection District's right-of-way, those projects are inspected but are invariably part of larger project and the lead agency for that project is the jurisdiction with land use authority permitting the design and building of that larger project.

6.3.1 Review Grading and Construction Permit Applications for SWPPP Requirements

Prior to approving a grading permit, the Permittees require a SWPPP be submitted for projects greater than one acre. Additionally, as is mandatory for all construction related activity disturbing one or more acres, Permittees require proof of filing an NOI for projects subject to the General Construction Permit. The SWPPP remains in effect until the construction site is stabilized and all construction activity is completed. The SWPPP includes identification of potential pollutant sources and the design, placement and maintenance of BMPs to effectively prevent the entry of pollutants from the construction site to the storm drain system. In addition, the Permittees require construction projects to include the following requirements:

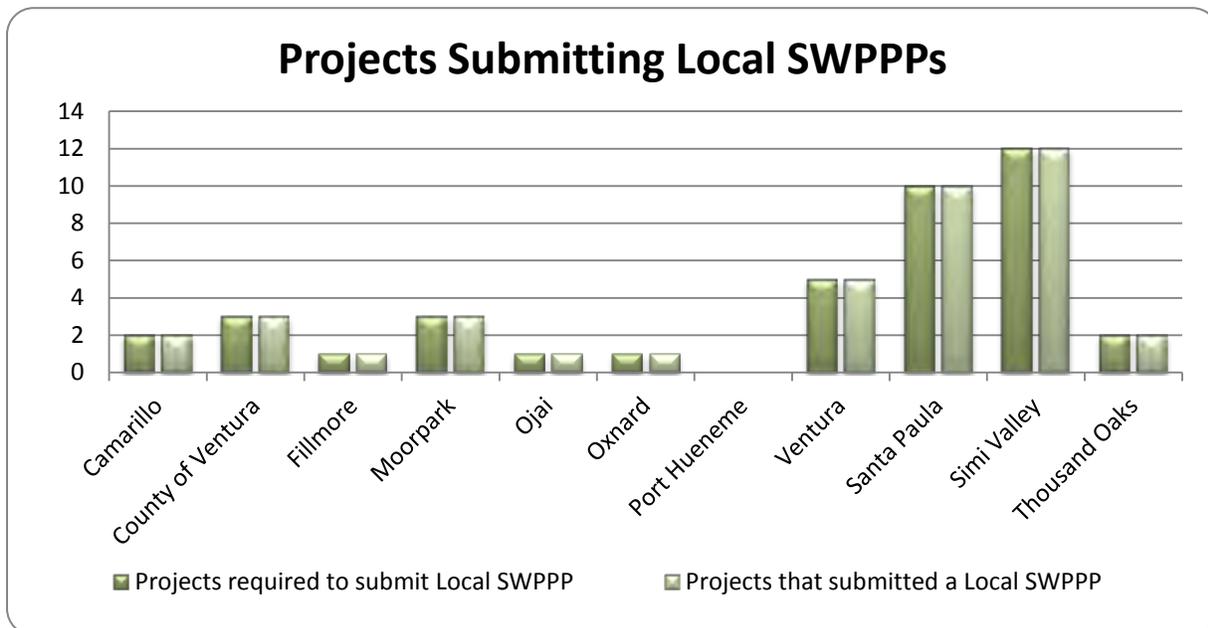

- Erosion from slopes and channels will be eliminated by implementing BMPs, including but not limited to, inspecting graded areas during rain events, planting and maintaining vegetation on slopes and covering erosion susceptible slopes;
- Sediments generated on the project site shall be retained using structural drainage controls;

- No construction-related materials, wastes, spills or residues shall be discharged from the project site to streets, drainage facilities or adjacent properties by wind or runoff;
- Non-stormwater runoff from equipment and vehicle washing and any other activity shall be contained at the project site;

The Permittees have also incorporated SWPPP provisions in their own construction projects resulting in soil disturbance of one acre or more, located in hillside areas, or directly discharging to an ESA. The Permittees include provisions delineating contractor responsibilities for SWPPP preparation, implementation and for performance of the work and ancillary activities in accordance with the SWPPP approved by the Permittee for the project. In some jurisdictions, Local SWPPPs were required and submitted for nearly all projects including those not exceeding Permit thresholds. This conservative approach underlines the importance the Permittees place on ensuring implementation of stormwater controls at construction sites.

This figure reflects the number of grading permits issued during this reporting period and does not necessarily reflect the number of active construction projects. This is due to the fact that some larger projects may take longer than a year to complete. Conversely, not all projects that received grading permits granted during the permit year actually began grading and construction. Because of these facts the number of active projects requiring inspection does not always match the number of grading permits granted. A project may be operating under a grading permit granted the previous year, or the grading permits may have been granted after the wet season so there was no opportunity for a wet season inspection, so the number of permits and projects inspected rarely match.

Figure 6-1 Local SWPPPs

6.3.2 Requirements for Projects Subject to the General Stormwater Permit

The Permittees require all construction projects subject to the General Stormwater Permit for Construction Activities to submit proof of filing a NOI prior to issuing a grading permit. Proof of filing a

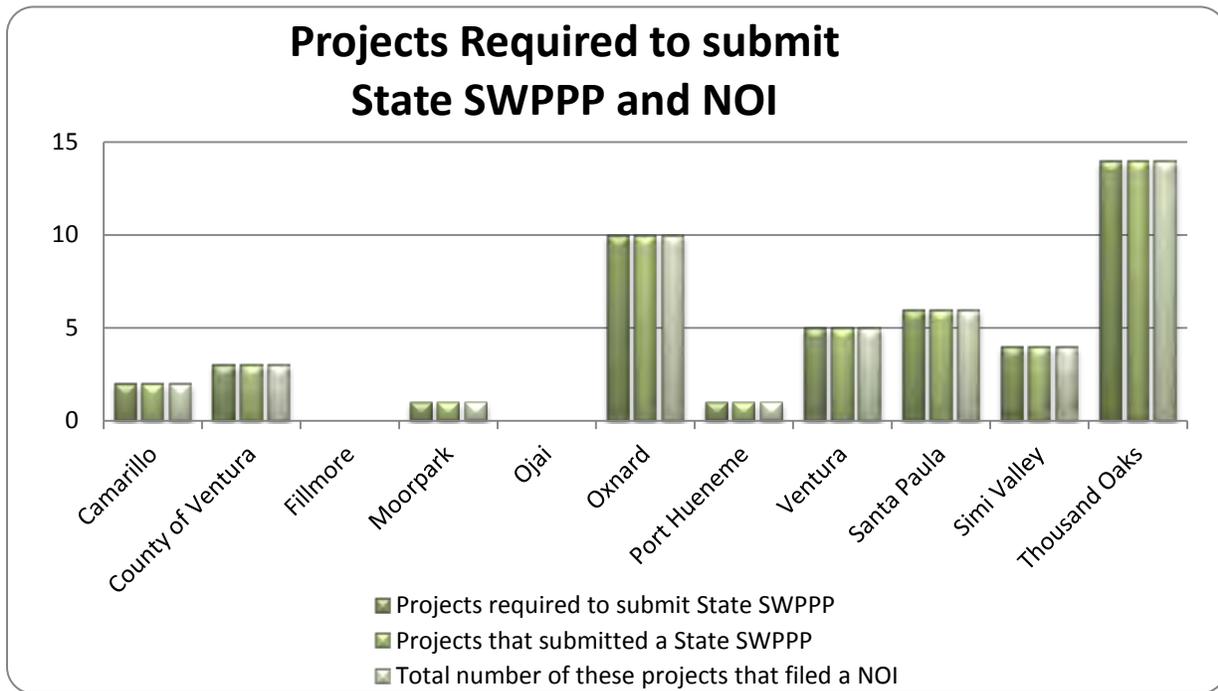

NOI can include a copy of the completed NOI form and a copy of the check sent to the State Water Resources Control Board (SWRCB), or a copy of the letter from the SWRCB with the Waste Discharge Identification Number (WDID) for the project.

Permittees inspect more construction sites than are required to submit a SWPPP, and inspect them more frequently for stormwater compliance than the permit requires.

In addition, the Permittees will file NOIs with the SWRCB and pay the appropriate fees when Permittee construction projects require coverage under the General Construction Permit. The NOIs and appropriate fees are sent to the State prior to the commencement of any construction activity covered by the General Construction Permit. A copy of the NOI is kept with the project files and in the SWPPP for the project.

Projects subject to the requirements of the General Construction Permit currently include those involving clearing, grading, or excavation resulting in soil disturbances of at least one acre. Permittee emergency work and routine maintenance projects do not require preparation of a SWPPP. That does not imply that stormwater controls are not implemented during these activities. Routine maintenance and emergency projects are performed in accordance with the Permit’s requirements for Public Agency Activities.

Figure 6-2 State SWPPPs and NOIs

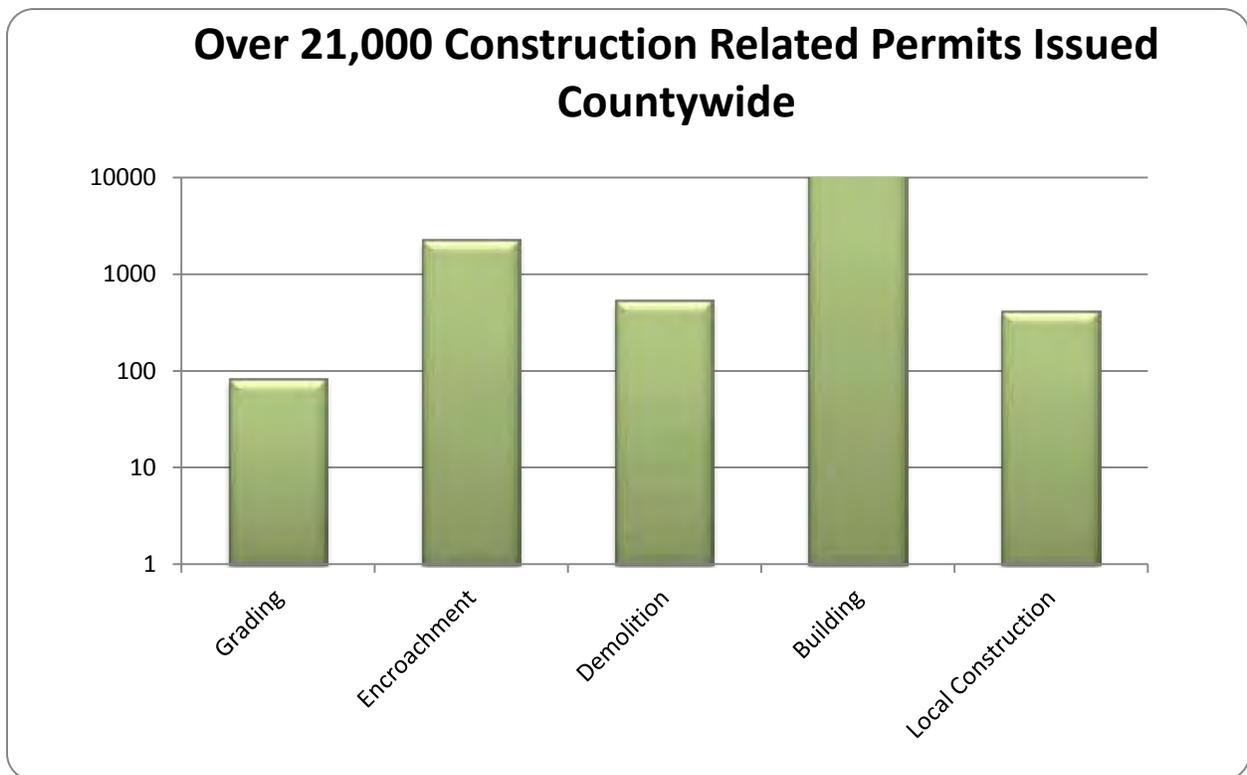

6.4 INVENTORY – DC2

The Construction Projects Inventory Control Measure involves tracking construction sites from the planning stage to completion. This is essential for ensuring that stormwater pollutants are reduced to the MEP. Maintaining a database to track all stages of the construction process is the foundation of

construction-related source identification and helps to ensure that pollution prevention and source control are emphasized during all phases of the construction project. The permitting process is also an opportunity to provide stormwater education and outreach to the construction community and to emphasize the penalties that can be incurred with non-compliance.

The Permittees have programs in place to track all grading, encroachment, demolition, and building permits as required by the NPDES Permit. In order to ensure the appropriate BMPs are being implemented when soil disturbing activities are taking place, the Permittees focus on the grading permit process to identify projects and the level of BMPs required. This has been determined as the most effective way to track projects with a potential to impact water quality as many encroachment, building, and other permits that are not associated with grading activities do not present the same level of risk to stormwater quality.

6.5 INSPECTIONS AND BMP IMPLEMENTATION – DC3

The Inspection and BMP Implementation Control Measure is critical to the ultimate success of the Development Construction Program Element. An effective construction site inspection program requires having adequate legal authority to enforce Permittee requirements, tracking active construction sites to identify repeat violators, and conducting inspections to ensure the sources are identified and that BMPs are being implemented and maintained. The inspection program also provides the basis for notifying the Regional Water Board when inspectors identify non-compliant sites including non-filers or repeat violators.

Figure 6-4 Site Inspections and Follow-Up

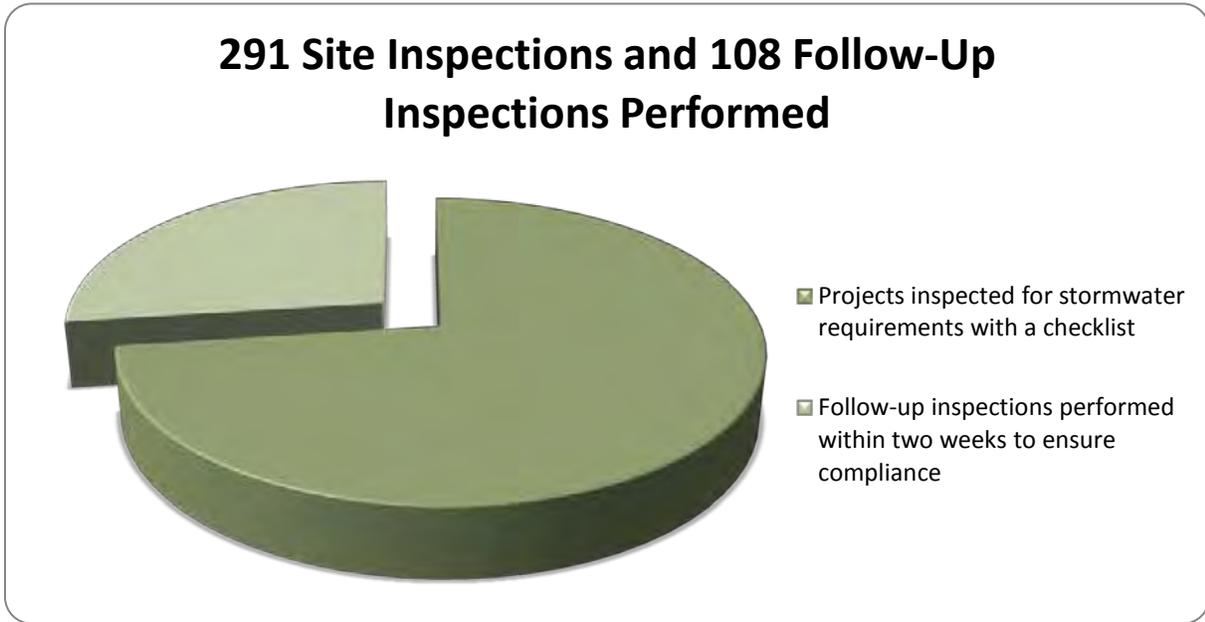

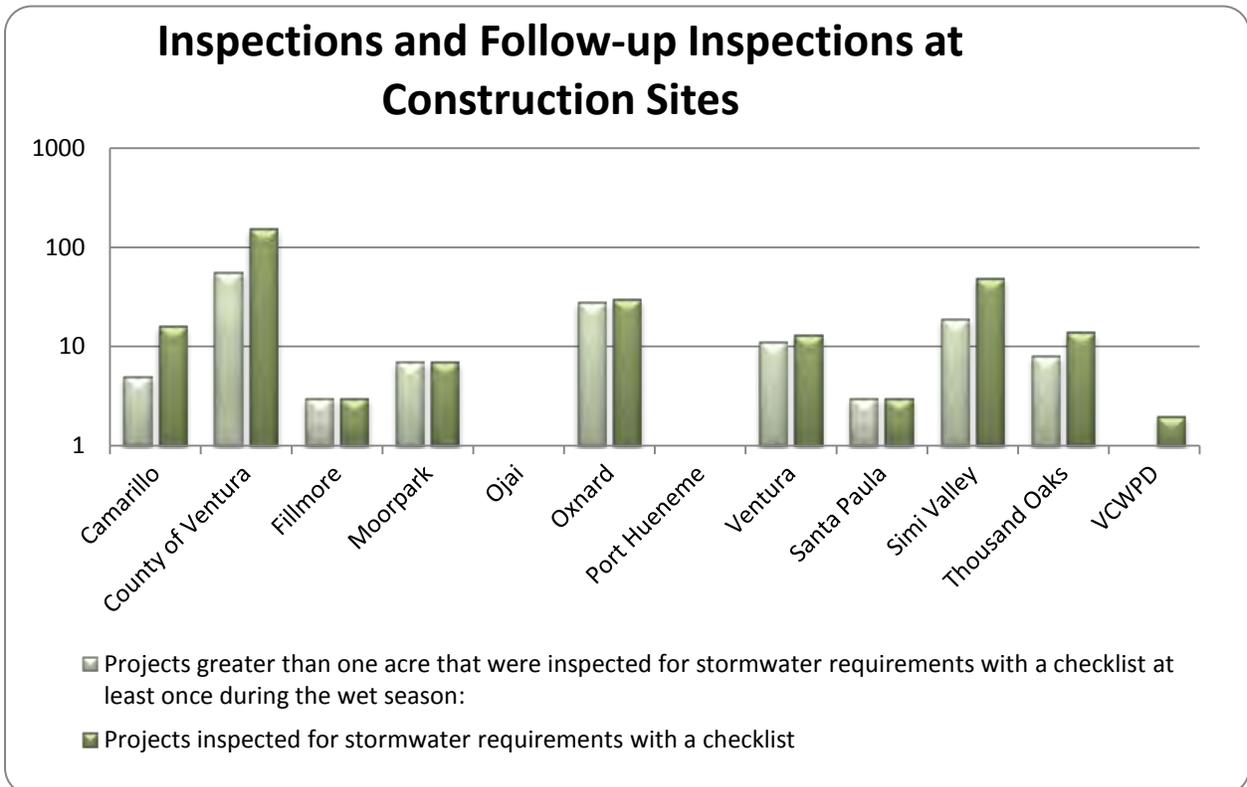

Figure 6-5 Construction Inspections and Follow-up Inspections

6.5.1 Inspect Construction Sites

The Permittees inspect all active construction sites for the implementation of stormwater quality controls a minimum of once during the wet season, and all construction sites with SWPPPs a minimum of once during the wet season to determine if the SWPPP is adequately implemented. During these site inspections, a checklist is completed to document inspection results. If it is determined the SWPPP is not adequately implemented, or when there is evidence of a reasonable potential for sediment, construction materials, wastes, or non-stormwater runoff to be discharged from the project site, the Permittees will inform the responsible party of what needs to be corrected and conduct a follow-up inspection within two weeks, but most often it is much sooner. The follow-up inspections are not always scheduled and often the response needed to correct the situation does not require two weeks to implement.

6.5.2 Implementation of Enhanced Practices at “High Risk” Sites

Construction sites located on hillsides, adjacent to CWA 303(d) listed waters for siltation or sediment, and directly adjacent to ESAs are termed "high risk" sites. The Permittees ensure implementation of enhanced practices such as increased BMP inspection and maintenance requirements at "high risk" sites to ensure that they do not create a threat to water quality.

The Permit requires that "high risk" sites be inspected by the project proponent's Qualified SWPPP Developer or Qualified SWPPP Practitioner or personnel or consultants who are Certified Professionals in Erosion and Sediment Control (CPESC) at the time of BMP installation, at least weekly during the wet season, and at least once each 24 hour period during a storm event that generates runoff from the site. Many of the permittees did not have any designated high risk construction sites but did have the program in place to identify and implement the added requirements.

Performance Standard 6-7

Watershed Protection	<input checked="" type="checkbox"/>		

6.5.3 Inspect for Post-Construction Controls

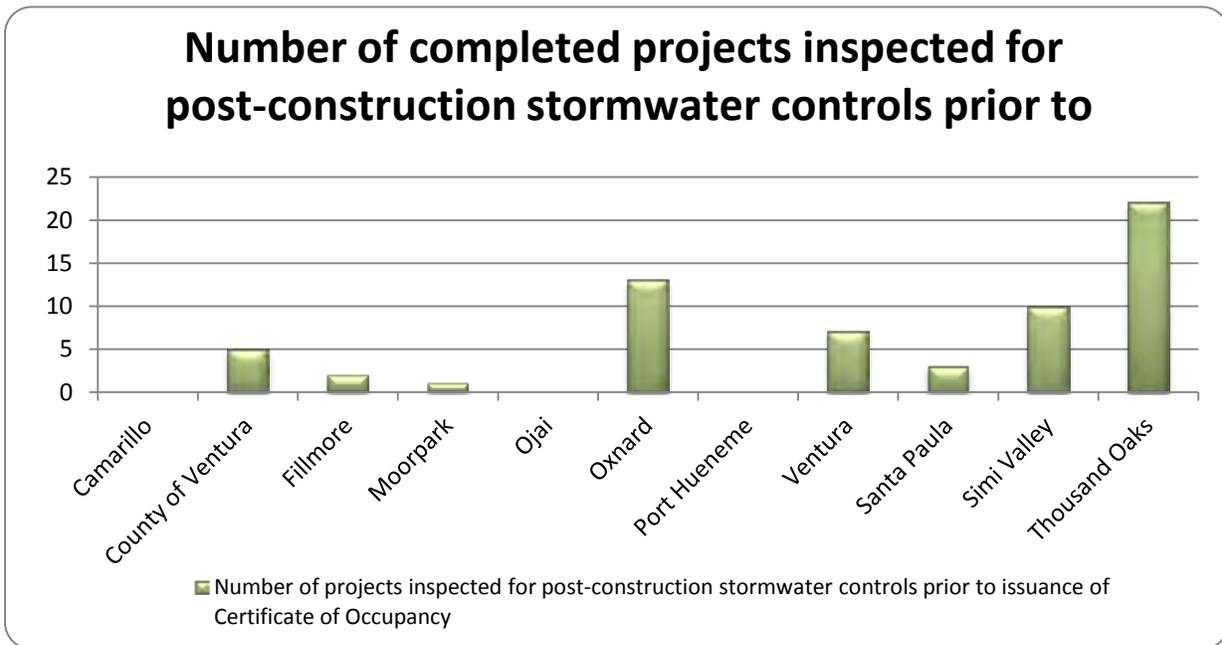

The Permittees inspected the site design as constructed, source control and treatment control BMPs conditioned during the development process to verify that they have been constructed in compliance with all specifications, plans, permits, ordinances, and the MS4 permit prior to approving and/ or signing off for occupancy and issuing the Certificate of Occupancy for all construction projects subject to post-construction controls. Permanent BMPs may be installed at any point during the construction process and therefore may be exposed to runoff conditions much worse than their intended design. The Permit also requires inspections to ensure that the BMPs are in good operating condition and are not in need of maintenance. These inspections are routinely performed at the same time to be cost efficient and to use the leverage the Certificate of Occupancy provides the Permittee. This requirement is in the Permit in Section F – Construction, and also Section E – Planning and Land Development.

As stated previously, the number of projects reaching the final stages of construction and requesting a Certificate of Occupancy will not directly match the number of active construction sites, or grading permits issued due to the elapsed time from permitting, to project initiation, completion and finally occupancy.

Performance Standard 6-10

Inspected constructed site design, source control and treatment control BMPs to verify constructed in compliance with all specifications prior to approving issuing the Certificate of Occupancy

6.6 ENFORCEMENT – DC4

The Enforcement Control Measure outlines the progressive levels of enforcement applied to construction sites that are out of compliance with local ordinances and establishes the protocol for referring apparent violations of construction sites subject to the General Construction Permit to the Regional Water Board. The progressive enforcement and referral policy, as well as the accompanying legal authority, is an important tool for providing a fair and equitable approach to bringing contractors and developers into

compliance with the Permittees' municipal code requirements. Enforcement actions range from verbal warnings to the issuance of stop work orders. Legal action may also be taken, although is rarely necessary, as in almost all cases stopping work at a site will focus the developers attention to the BMPs. For repeat offenders, or contractors that have not filed appropriate applications, the referral policy includes notification to the Regional Water Board.

6.6.1 Enforcement Action to Achieve Compliance

When a construction site fails to comply with the SWPPP, minimum BMPs or other stormwater requirements, a Permittee implements the appropriate notification and enforcement procedures. There are five general levels of notification and enforcement for most stormwater related problems for construction projects. These are: Verbal Notification, Job Memorandum, Notice of Violation, Administrative Compliance Order, and Stop Work Order. Sites that are permitted under the construction activities general permit (CASGP) are also referred to the RWQCB if they fail to achieve compliance and a good faith effort has been made by the Permittee to achieve compliance. At a minimum that is two follow-up inspections within three months, and at least two warning letters or NOV's. The decision to use any level of enforcement is based upon the severity of the violation(s). Severe violations may result in all construction activities being stopped at the job site and not allowed to proceed until compliance is achieved. The Regional Board may be notified of severe violations at sites under the CASGP if the situation warrants immediate attention. If such a case occurs, the Permittees will work with Board staff in identification of owners and operators, assist with joint inspections, and other efforts to reduce pollutants from entering an MS4.

Figure 6-7 Enforcement at Construction Sites

6.6.2 Implement Progressive Enforcement and Referral Policy

During the reporting year one construction site failed to return to compliance and was referred to the Regional Water Board for enforcement actions under the CAGSP. Referrals to the Regional Water Board would be summarized in Table 6-2.

Table 6-2 Summary of Referrals

WDID Number	Reason for Referral
N/A	No Referrals in 2011/12

6.6.3 Refer Non-filers Under the CASGP or the Small LUP General Permit

Countywide all construction activities that were required to file for coverage under the CASGP or the Small Linear Underground Project Permit did so. This is because the Permittees have developed the appropriate programs and procedures to ensure that local permits are not granted until the project proponent can provide adequate proof of state permit coverage.

6.6.4 Investigation of Complaints Regarding Facilities - Transmitted by the Regional Water Board Staff

The Permittees are required to initiate an initial investigation of complaints transmitted by the Regional Water Board Staff (other than non-storm water discharges) on the construction site(s) within its jurisdiction. During the reporting period the Regional Board did not transmit any complaints for Permittee investigation; any reports received would be summarized in Table 6-3 Summary of Complaints Transmitted by the Regional Water Board.

Table 6-3 Summary of Complaints Transmitted by the Regional Water Board

Permit #	Initial Investigation conducted within 1 business day? (Y/N)	Inspection of the Facility and its Perimeter? (Y/N)
None	**	**

6.6.5 Support of Regional Water Board Enforcement Actions

If the Regional Water Board is aware of non-compliance at a construction site they may request assistance from the Permittees to support their formal enforcement actions. Fortunately during the reporting period the Permittees were able to use their local authority to keep all construction sites in compliance and assistance to the Regional Water Board enforcement actions was not needed.

Table 6-4 describes what kind of assistance the Permittees could provide and will be used in future reports to summarize any enforcement action assistance.

Table 6-4 Summary of Complaints Transmitted by the Regional Water Board

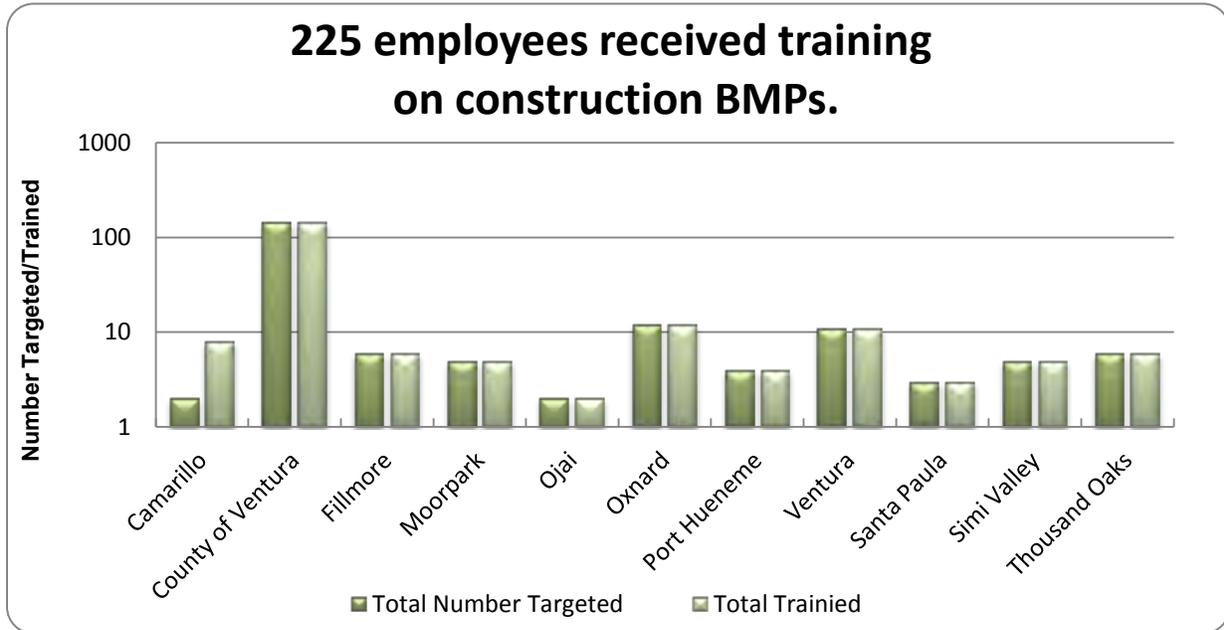

Permit #	Assisted in Identification of Current Owners/ Operators of Properties/Sites? (Y/N)	Provided Staff for Joint Inspections with Regional Water Board Inspectors? (Y/N)	Appeared to Testify as Witnesses in Regional Water Board Enforcement Hearings? (Y/N)	Provided Copies of Inspection Reports and Other Progressive Enforcement Documentation? (Y/N)
**	**	**	**	**

6.7 TRAINING – DC5

Training is important for the implementation of the Development Construction Program Element. An effective training program is one of the best pollution prevention BMPs that can be implemented because it prompts behavioral changes that are fundamentally necessary to protect water quality. The Permittees target employees involved with construction engineering and inspection for training regarding the requirements of the Program for Construction Sites. Training methods varied amongst the Permittees and ranged from informal meetings, formal classroom training, and seminars to self-guided training. The Permittees also trained staff on the prevention, detection and investigation of illicit discharges and illegal connections (IC/ID) associated with construction activities. See Chapter 8 of this report for more information regarding IC/ID training.

During this reporting period, the Permittees trained over 200 key staff, including contractors whose interactions, jobs, and activities affect development construction in stormwater management, construction inspections, SWPCPs, SWPPPs, illicit discharge response, and non-stormwater discharges. Figure 6-8 depicts the number of staff trained in the program areas for each Permittee.

Figure 6-8 Construction Inspection Training

6.8 EFFECTIVENESS ASSESSMENT – DC6

Effectiveness assessment is a fundamental component for developing and implementing successful stormwater programs. In order to determine the effectiveness of the Development Construction Program, a comprehensive assessment of the program data is conducted as a part of the annual report. The results of this assessment are used to identify modifications that need to be made to the program. Each year the effectiveness assessment is reviewed and revised as needed.

By conducting these assessments and modifying the program as needed, the Permittees ensure that the iterative process is used as an effective management tool. Due to the types of data collected for the Development Construction Program, current assessments will primarily focus on Outcome Levels 1, 2 & 3.

- Outcome Level 1 (L1) answers the question: Did the Permittees implement the components of the Permit?
- Outcome Level 2 (L2) answers the question: Can the Permittees demonstrate that the control measure/performance standard significantly increased the awareness of its target audience?
- Outcome Level 3 (L3) answers the question: Can the Permittees demonstrate that the control measure/performance standard significantly modified the behavior of a target audience?

The following is an assessment regarding the effectiveness of the Development Construction Program.

6.8.1 Plan Review and Approval Process

Review Grading and Construction Permit Applications for SWPPP Requirements

Prior to approving a grading permit, the Permittees require a SWPPP be submitted for projects greater than one acre. (L1) All projects required to submit a State SWPPP, submitted a State SWPPP and filed a

NOI. (L1) Proof of filing a NOI included a copy of the completed NOI form and a copy of the check sent to the SWRCB, or a copy of the letter the SWRCB with the WDID for the project. (L1)

In some jurisdictions, Local SWPPPs were required and submitted for nearly all projects, including those not exceeding Permit thresholds. (L1)

The Permittees required proof of state permit coverage so that all construction activities that were required to file for coverage under the CASGP or Small Linear Underground Project Permit did so.

6.8.2 Inventory

The majority of the Permittees maintained an electronic system to track grading permits, encroachment permits, and any other municipal authorization to move soil. (L1) They required a copy of the SWPPP any time a transfer of ownership took place. Ownership transfer did not happen in each jurisdiction, so some Permittees did not have the opportunity to require a revised SWPPP. (L1)

Inspection and BMP Implementation

As shown in Figure 6-4, the Permittees inspected all active construction sites for stormwater quality requirements during routine inspections a minimum of once during the wet season,. (L1) (L2) For inspected sites that had not adequately implemented their SWPPPs, the Permittees conducted a follow-up inspection within two weeks. Most often, the follow-up inspection occurred much sooner. (L1) (L2) (L3) In addition, the majority of Permittees inspected each project that included roadbed or street paving, repaving, patching, digouts, or resurfacing roadbed surfaces to ensure that the minimum set of BMPs were implemented. This was routinely done at the same time inspections were performed to ensure all work was being performed according to the design and standards required of public works projects. (L1) (L2)

The Permittees required a CPESC to inspect the construction sites at the time of BMP installation, at least weekly during the wet season, and at least once each 24 hour period during a storm event that generated runoff from the site if the site was:

- Within, or adjacent to an ESA
- On a hillside
- Discharging into a sedimentation/siltation impaired water body listed on the CWA 303(d) list

Many of the permittees did not have any of these types of high risk construction sites but did have the program in place to implement the added requirements.

Prior to approving and/or signing off for occupancy and issuing the Certificate of Occupancy for all construction projects subject to post-construction controls, the majority of Permittees inspected the constructed site design, and source control and treatment control BMPs conditioned during the development process to verify that they have been constructed in compliance with all specifications, plans, permits, ordinances, and the MS4 permit, as shown in Figure 6-7.

6.9 ENFORCEMENT

Enforcement Action to Achieve Compliance

When a construction site fails to comply with the SWPPP, minimum BMPS or other stormwater requirements, a Permittee implements the appropriate notification and enforcement procedures. (L1) Sites

that are permitted under the CASGP are also referred to the RWQCB if they fail to achieve compliance in two weeks and a good faith effort has been made by the Permittee to achieve compliance. (L1) (L2)

Figure 6-8 shows each enforcement level and the relative number of enforcement actions taken. The Permittees did not make any referrals of violation of the new development and redevelopment post construction requirements and municipal stormwater ordinances to the Regional Water Board because there were no violations. (L1) No sites were referred to the Regional Water Board to take appropriate enforcement actions under the CAGSP.

Training

During this reporting period, the Permittees trained 226 key staff, double last year, including contractors whose interactions, jobs, and activities affect development construction in stormwater management, construction inspections, SWPCPs, SWPPPs, illicit discharge response, and non-stormwater discharges. (L1) 100% of targeted staff members received training on construction BMPs, as shown in Figure 6-8.

6.9 DEVELOPMENT CONSTRUCTION PROGRAM MODIFICATIONS

On an annual basis the Permittees plan to evaluate the results of the Annual Report, as well as the experience that staff has had in implementing the program, to determine if any additional program modifications are necessary to comply with the Clean Water Act requirement to reduce the discharge of pollutants to the MEP. Any key modifications made to the Development Construction Program Element during the next fiscal year will be reported in the following Annual Report.

7 Public Agency Activities

7.1 OVERVIEW

The Permittees own and operate public facilities, and build and maintain much of the infrastructure of the urban and suburban environment throughout their jurisdictions. Some programs under Public Agency Activities help remove pollutants before they reach receiving waters, and others focus on source control ensuring all the activities performed do not contribute to stormwater pollution to the maximum extent practicable. Therefore public agencies have a dual role: removing pollutants before they are transported by the storm drain system, and preventing pollution from being generated in the operation and maintenance of these facilities.

Permit requirements include both maintenance of infrastructure to remove pollutants and implementing control measures to prevent the generation or transport of pollutants. Maintenance activities include street sweeping and drainage facility inspection and cleaning. As part of their normal operations the Permittees conduct a number of activities (e.g., catch basin cleaning, street repairs, street sweeping) that have the potential to generate or mobilize pollutants. Control Measures in the Public Agency Activities Program Element are designed to ensure that these operations and maintenance activities are performed using processes and procedures to minimize the pollutants generated and the potential for pollutants to enter the storm drain system.

7.2 CONTROL MEASURES

The Permittees have developed several Control Measures and accompanying performance standards to ensure that the public agency activities permit requirements are effectively developed and implemented. For each Control Measure there are accompanying performance standards which, once accomplished, constitute compliance.

The Public Agency Activities Control Measures are organized to be parallel to the organization of the Permit and consist of the following:

Table 7-1 Control Measures for the Public Agency Activities Program Element

PA	Control Measure
PA1	Public Construction Activities Management
PA2	Vehicle Maintenance/Material Storage Facilities/Corporation Yards Management/Municipal Operations
PA3	Vehicle and Equipment Wash Areas
PA4	Landscape, Park, and Recreational Facilities Management
PA5	Storm Drain Operation and Management
PA6	Street And Roads Maintenance
PA7	Emergency Procedures
PA8	Training
PA9	Effectiveness Assessment

7.3 PUBLIC CONSTRUCTION ACTIVITIES MANAGEMENT 1-PA

The Public Construction Activities Control Measure provides protocols to be followed in the design and construction phases of capital projects undertaken by the Permittees. In essence, the Permittees will follow the Planning and Land Development and Construction Programs requirements for all Permittee-owned or operated public construction projects. Those requirements include complying with the Development Planning Program requirements at public construction projects and all the Development Construction Program requirements at Permittee owned or operated construction sites including requiring the development of SWPCP for projects that disturb less than 1 Acre.

Performance Standard 7-1

Comply with all the Development Planning Program requirements at public construction projects.			
	Yes	No	N/A
Camarillo	<input checked="" type="checkbox"/>		
Ventura County	<input checked="" type="checkbox"/>		
Fillmore	<input checked="" type="checkbox"/>		
Moorpark	<input checked="" type="checkbox"/>		
Ojai	<input checked="" type="checkbox"/>		
Oxnard	<input checked="" type="checkbox"/>		
Port Hueneme	<input checked="" type="checkbox"/>		
Ventura	<input checked="" type="checkbox"/>		
Santa Paula	<input checked="" type="checkbox"/>		
Simi Valley	<input checked="" type="checkbox"/>		
Thousand Oaks	<input checked="" type="checkbox"/>		
Watershed Protection	<input checked="" type="checkbox"/>		

Performance Standard 7-2

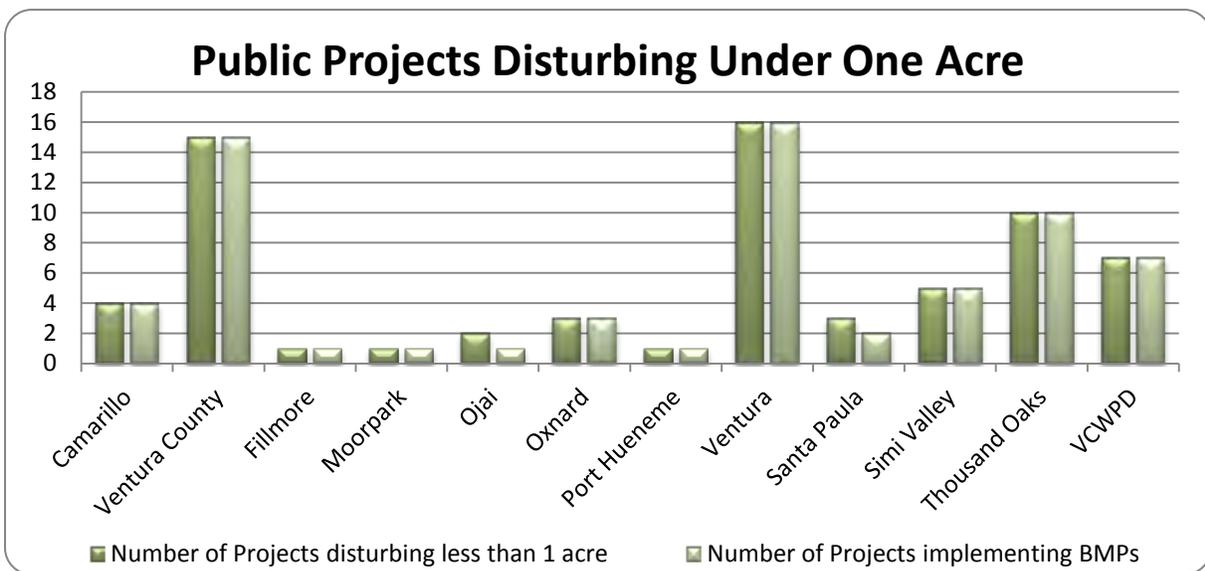

Grading or building permits are not routinely granted for public construction projects within an agency's jurisdiction and so identifying and defining small construction projects is less straight forward. To ensure that extremely small projects such as installing a stop sign or providing wheelchair access to a sidewalk meet permit requirements the Permittees have adopted standard practices to serve as the SWPCP. The practices include the BMPs identified in the permit for construction projects under one acre.

Comply with all the Development Construction Program requirements at Permittee owned construction sites

Figure 7-1 Public Projects Disturbing Less Than One Acre

Larger projects have requirements in the construction bid documents which require the contractor to draft and implement an approved SWPCP with the size appropriate BMPs. All public constructions projects are required to be in compliance the State’s requirements under the Construction Activities General Stormwater Permit (CAGSP). Figure 7-2 indentifies how many projects the Permittees had that fell under those requirements.

Figure 7-2 Public Projects Disturbing Greater Than One Acre

7.4 VEHICLE MAINTENANCE/MATERIAL STORAGE FACILITIES/CORPORATION YARDS MANAGEMENT/MUNICIPAL OPERATIONS – PA2

The Vehicle Maintenance/Material Storage Facilities/Corporation Yards Management/Municipal Operations Control Measure addresses pollutants entering the storm drain system from Permittee-owned/leased facilities (e.g., vehicle equipment maintenance facilities, material storage facilities, collectively referred to as corporation yards). There are other non-operation oriented facilities that are owned or leased by the Permittees where these permit conditions are not relevant, such as libraries, parks, and office buildings. However, these facilities are still required to comply with all other applicable permit requirements such as pesticide use. Camarillo recently installed covers over the material bunkers at their Corporation yard. In addition, solar panels were installed on top of the covers which will provide power to several buildings at the corporation yard.

The Permittees’ corporation yards support operation and maintenance activities within their jurisdiction. Corporation yards are operated and maintained by the Permittees for the following activities or facilities:

- Vehicle and equipment
- Storage and parking
- Maintenance

Thousand Oaks’ car wash facility that drains to wastewater treatment plant

- Fueling
- Washing and cleaning
- Sign painting activities
- Bulk material storage areas

Material storage covers in Camarillo also support solar panels

7.4.1 Implement Required BMPs for each Facility

The Permittees have written SWPCPs for corporation yards to ensure implementation of appropriate BMPs, including those identified in Table 10 of the Permit. The SWPCPs were required under the previous permit and serve to help implement the current permit requirements. The SWPCPs call for annual inspections to be performed and documented by trained staff. Any insufficiencies identified during inspections are quickly corrected by facility staff.

Table 7-2 Summary of Permittee-Owned and Leased Facilities

7.5 VEHICLE AND EQUIPMENT WASH AREAS – PA3

The Vehicle and Equipment Wash Areas Control Measure addresses pollutants entering the storm drain system from Permittee-owned/leased vehicle and equipment wash areas. The Permit provides several options to eliminate wash water discharges from vehicles and equipment washing facilities by implementing one of the following:

- Self-contain, and haul-off for disposal;
- Equip with a clarifier;
- Equip with an alternative pre-treatment device; or
- Plumb to the sanitary sewer.

The Permittees have been successful in implementing applicable BMPs to eliminate wash water discharges from vehicles and equipment washing. As municipal facilities are constructed, redeveloped, or replaced all vehicle wash areas will be plumbed to the sanitary sewer or be self-contained and all wastewater disposed of legally.

7.6 LANDSCAPE, PARK, AND RECREATIONAL FACILITIES MANAGEMENT – PA4

The Landscape, Park, and Recreational Facilities Management Control Measure ensure that the discharges of pollutants from the Permittees’ use and storage of fertilizers and pesticides are reduced. The control measures include the use of BMPs that promote the use of integrated pest management (IPM) and retention and planting of native plant species requiring less water and chemical augmentation to remain healthy.

7.6.1 Implement IPM Program

A model integrated pest management (IPM) program was drafted through the Public Agencies Activities Subcommittee and used as a template by the Permittees to develop their own plans. This standardized protocol was posted on the Program’s website November 2009. The due date in the Permit for implementation of IPM plans was October 8, 2010.

The purpose of this standardized protocol is to define an application protocol for the routine and non-routine application of pesticides, fertilizers, and herbicides (including pre-emergents). This protocol provides a comprehensive policy to comply with the Ventura County Permit.

The intent is to focus on preventing pesticides, fertilizers, and herbicides from entering the storm drain system and discharging to receiving waters. This protocol is applicable to 1) the outdoor use of pesticides, herbicides, and fertilizers; 2) the use of pesticides and fertilizers where the materials may come into contact with precipitation; 3) the use of pesticides, herbicides, and fertilizers where these materials may come into contact with runoff (natural or irrigation); and 4) the use of pesticides, herbicides, or fertilizers anywhere where they may be directly or indirectly discharged to a storm drainage system.

The protocol is applicable to Permittee staff and contracted services that apply pesticides, fertilizers, or herbicides. Such staff commonly include, park, public works, building/grounds maintenance, and pesticide application staff. It is not applicable to the indoor use of pesticides, but is applicable to the consequential outdoor handling, mixing, or disposal of materials related to indoor use. This protocol also does not apply when another NPDES permit and/or abatement orders are in effect at the selected site. Furthermore, this protocol is not intended to replace federal or state requirements or provide complete directions for applying, handling, transporting, mixing, or storing pesticides, fertilizers, or herbicides.

An effective IPM program should include the following elements:

- Pesticides are used only if monitoring indicates they are needed according to established guidelines.

- Treatment is made with the goal of removing only the target organism.
- Pest controls are selected and applied in a manner that minimizes risks to human health, beneficial, non-target organisms, and the environment.
- Use of pesticides, including Organophosphates and Pyrethroids do not threaten water quality.
- Partner with other agencies and organizations to encourage the use of IPM.
- Adopt and verifiably implement policies, procedures, and/or ordinances requiring the minimization of pesticide use and encouraging the use of IPM techniques (including beneficial insects) in the Permittees' overall operations and on municipal property.
- Policies, procedures, and ordinances shall include commitments and timelines to reduce the use of pesticides that cause impairment of surface waters by implementing the following procedures:
 - Quantify pesticide use by its staff and hired contractors.
 - Prepare and annually update an inventory of pesticides used by all internal departments, divisions, and other operational units.
 - Demonstrate reductions in pesticide use.

The prevention of pesticides from harming non-target organisms is the primary goal of the Permittees IPM program. The Permit also asks for the demonstration of a reduction in pesticide use, however that is not as simple as comparing one year's use to another. Many factors go into the decision to use pesticides and year to year variables can have a significant impact on that decision. For example, an above average wet year will require more weed abatement than a dry year. The need to address an insect infestation before it spreads will require an intensified use of pesticides in that area. Since year to year reductions cannot be accurately measured due to variable needs, the reduction in use of pesticides by the Permittees will be compared to the amount of pesticides that would have been used under a non-IPM program.

Performance Standard 7-4

Implement an integrated pest management (IPM) program consistent with Permit			
	Yes	No	Draft
Camarillo	<input checked="" type="checkbox"/>		
Ventura County	<input checked="" type="checkbox"/>		
Fillmore	<input checked="" type="checkbox"/>		
Moorpark	<input checked="" type="checkbox"/>		
Ojai		<input checked="" type="checkbox"/>	
Oxnard	<input checked="" type="checkbox"/>		
Port Hueneme	<input checked="" type="checkbox"/>		
Ventura	<input checked="" type="checkbox"/>		
Santa Paula	<input checked="" type="checkbox"/>		
Simi Valley	<input checked="" type="checkbox"/>		
Thousand Oaks	<input checked="" type="checkbox"/>		
Watershed Protection	<input checked="" type="checkbox"/>		

7.6.2 Maintain and Expand Internal Inventory on Pesticide Use

Permittees require all staff applying pesticides to be either certified by the California Department of Food and Agriculture, or under the direct on-site supervision of a certified pesticide applicator, as defined in the standardized protocol. Permittees have also restricted the purchase and use of pesticides and herbicides to certified staff.

Performance Standard 7-5

Prepare an annual update an inventory of pesticides used by all internal departments and hired contractors			
	Yes	No	N/A
Camarillo	<input checked="" type="checkbox"/>		
Ventura County	<input checked="" type="checkbox"/>		
Fillmore	<input checked="" type="checkbox"/>		
Moorpark	<input checked="" type="checkbox"/>		
Ojai	<input checked="" type="checkbox"/>		
Oxnard	<input checked="" type="checkbox"/>		
Port Hueneme	<input checked="" type="checkbox"/>		
Ventura	<input checked="" type="checkbox"/>		
Santa Paula	<input checked="" type="checkbox"/>		
Simi Valley	<input checked="" type="checkbox"/>		
Thousand Oaks	<input checked="" type="checkbox"/>		
Watershed Protection	<input checked="" type="checkbox"/>		

Permittees that contract out for pesticide applications have included contract provisions requiring the contract applicator meet all requirements of this program. Contract language includes compliance with the standardized protocol, the prohibitions and requirements for certification, and supervision of pesticide applicators.

Performance Standard 7-6

7.7 STORM DRAIN OPERATION AND MANAGEMENT – PA5

The Storm Drain Operation and Management Control Measure provides for the long-term performance and integrity of the Permittees' storm drain system. The Permittees must prioritize catch basins for cleaning based on the required level of maintenance, and all catch basins are marked with a storm drain message, whether stenciled or permanently imprinted. This Control Measure also includes a requirement for special events to prevent debris accumulation in catch basins and storm drains.

Establish standard protocols for routine and non-routine application of pesticide consistent with the permit requirements			
	Yes	No	N/A
Camarillo	<input checked="" type="checkbox"/>		
Ventura County	<input checked="" type="checkbox"/>		
Fillmore	<input checked="" type="checkbox"/>		
Moorpark	<input checked="" type="checkbox"/>		
Ojai	<input checked="" type="checkbox"/>		
Oxnard	<input checked="" type="checkbox"/>		
Port Hueneme	<input checked="" type="checkbox"/>		
Ventura	<input checked="" type="checkbox"/>		
Santa Paula	<input checked="" type="checkbox"/>		
Simi Valley	<input checked="" type="checkbox"/>		
Thousand Oaks	<input checked="" type="checkbox"/>		
Watershed Protection	<input checked="" type="checkbox"/>		

7.7.1 Implement Storm Drain System Mapping

The Permit requires that the Permittees to create a map at a scale and in a format specified by the Principal Permittee showing the location and length of underground pipes 18 inches and greater in diameter, and channels within their permitted area. A schedule was provided to allow time to develop the needed information. The first due date was October 6, 2010. Since Ventura Counties cities are all separated by open space and the MS4 from one city does not discharge to another, the need to integrate the maps into a countywide storm drain map is not as imperative as the need for a Permittee to be able to know what is upstream from any point in their MS4, and where that water will discharge. Given that the priority for the mapping is internal to the agency operating the system, the Permittees were given the autonomy to decide what form of mapping will work best for their needs. All maps will be incorporated into the Principal Permittee's Watershed Protection District, GIS system as best as possible. This incorporation will allow for other formats to be available and viewed when needed.

Performance Standard 7-7

Prepare a map or list of catch basins, with GPS coordinates, designations, and rationale for designations			
	Yes	No	in progress
Camarillo	<input checked="" type="checkbox"/>		
Ventura County	<input checked="" type="checkbox"/>

Simi Valley			<input checked="" type="checkbox"/>
Thousand Oaks	<input checked="" type="checkbox"/>		
Watershed Protection			N/A

7.7.2 Implement Catch Basin Maintenance Program

Each Permittee developed the criteria and method of a catch basin mapping and prioritization system for their agency. This is due to the different types of databases, mapping systems, infrastructure, and methods used by the Permittees for inspection and cleaning. The Permit does not specify the criteria for designating catch basin priorities, nor require a uniform system of mapping catch basins. The Permittees have begun to implement catch basin cleaning schedules based upon the prioritization designations as required by the Permit, however, the requirement of a list or map of catch basins with their GPS coordinates and their prioritization designation was due July 8 2011. Figure 7-4 through Figure 7-7 shows the Permittees' efforts on prioritization, inspection and maintenance.

Figure 7-3 Example of Storm Drain Map

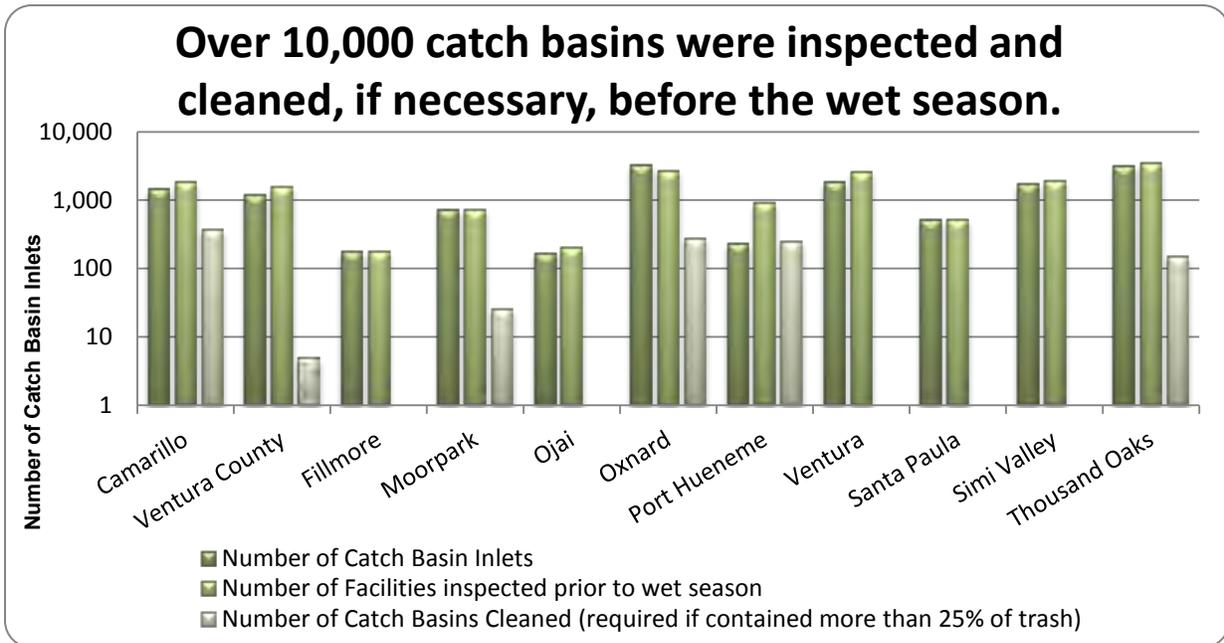

Permittees routinely inspect catch basins and other drainage facilities that are a part of their system. These inspections are scheduled and completed in accordance with the requirements of the catch basin prioritization (due July 2011). The prioritization requires:

- Priority A inspected 3 times a wet season and once during the dry season;
- Priority B inspected once during the wet season and once during the dry season;
- Priority C inspected a minimum of once per year.

Over 230 tons of debris was removed from catch basins countywide through the storm drain maintenance program.

Figure 7-4 Catch Basin Inspections and Cleaning

Catch Basin Cleaning Using a Vacuum Truck

Inspections include the visual observation of each catch basin, and open channel to determine if the device or conveyance has accumulated trash, sediment or debris requiring removal. All debris removed (including trash and natural debris such as leaves from street trees) from the system is disposed of properly and therefore represents pollutants that would have been washed downstream to a receiving water. For catch basins, “as-needed cleaning” occurs whenever trash, sediment, or debris accumulation is found to be at least 25% of capacity. Watershed Protection District cleans and maintains their flood control facilities, but does not operate any catch basins that receive runoff directly from streets or roads.

Performance Standard 7-8

Inspect the legibility of the catch basin label by all inlets before the beginning of the wet season			
	Yes	No	N/A

Figure 7-5 Priority A Catch Basins Inspected and Cleaned

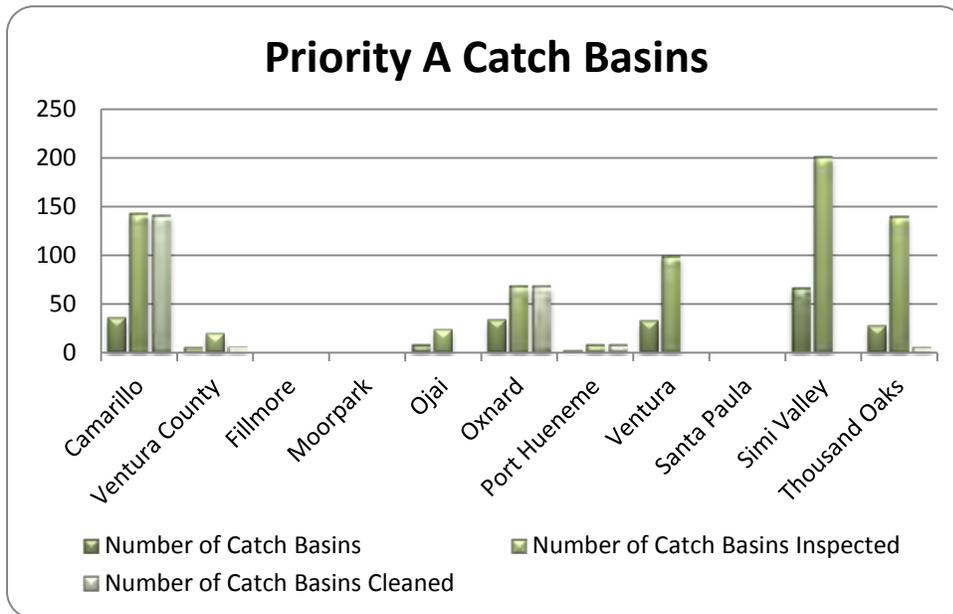

Figure 7-6 Priority B Catch Basins Inspected and Cleaned

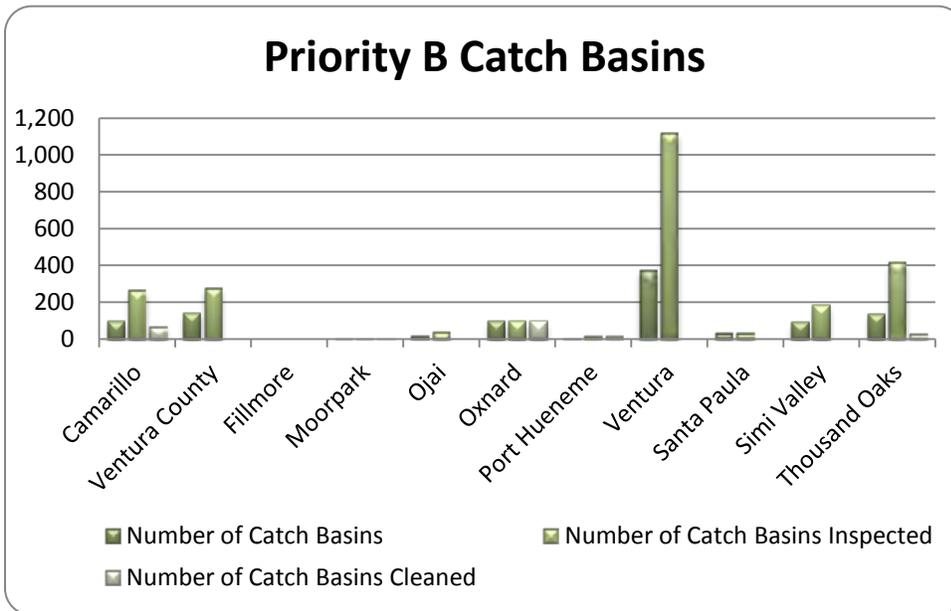

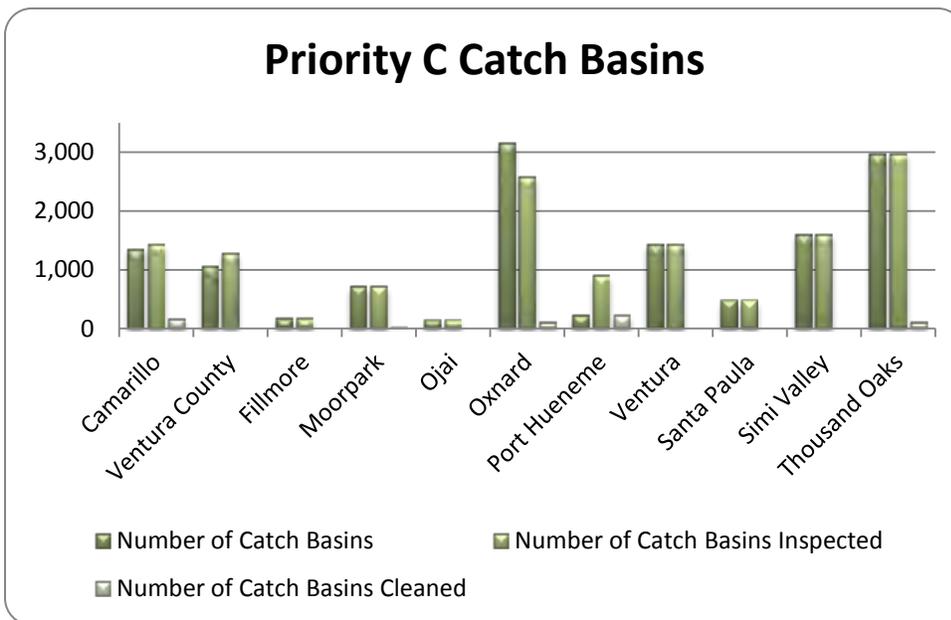

Figure 7-7 Priority C Catch Basins Inspected and Cleaned

7.7.3 Install Trash Receptacles

Permittees have identified the bus stop areas which are typically located in commercial areas and near schools as areas to install trash receptacles. All Permittees have installed trash receptacles at areas subject to high trash accumulation. Commercial areas are typically required to install trash receptacles at store fronts to aid in proper disposal. Trash programs usually involve agency solid waste divisions who bring their expertise in performing trash audits to determine the need for additional trash receptacles.

Performance Standard 7-9

Trash receptacles, or equivalent trash capturing devices in areas subject to high trash generation within jurisdiction

Thousand Oaks	<input checked="" type="checkbox"/>		
Watershed Protection	<input checked="" type="checkbox"/>		

Camarillo - Camarillo installed 31 full capture connector pipe screen trash devices at all priority A locations throughout the city, in addition they installed trash receptacles at the city's bus stop areas which are typically located in commercial areas and near schools. Trash containers were also installed at entrances to city-maintained trails and the city's park. In addition, the city contracted special monthly trash cleanups along major arterials in the commercial areas of the Revolon Slough/Beardsley wash subwatershed. Also, the city mailed letters to all commercial businesses/property managers (42) in the Revolon Slough/Beardsley wash subwatershed requesting they maintain their property and keep it free of litter. Further, via California Coastal Cleanup Day, the City held cleanups at two locations in which over 340 volunteers removed approximately 1,800 lbs. of trash and recyclables. The City also published an article, “Do you Know Where Your Litter Goes?”, in the May/June 2012 Cityscene newsletter which was mailed to all residents.

County of Ventura – Public Works Agency - Transportation provides for street sweeping in high trash (Priority A) areas. Trash and litter pick-up are required by the Encroachment Permits. All public park facilities are equipped with trash receptacles and covered 3-yard bins for public use. Trash containers are checked and emptied as needed on a daily basis or more often as required in accordance with use patterns.

Airports staff patrols facilities and is able to identify moderate trash areas, especially prior to rain and during high wind events.

Hard working trash excluder

Fillmore - The city has regular Public Works crew and trash truck to empty receptacles and to clean areas of high trash. During special events the use permits require additional trash facilities.

Moorpark – Annual inspections of the City's catch basins determine whether or not any Priority A catch basins exist. A Priority A catch basin is defined as any catch basin that is found with 25% or more of trash. Majority of commercial business areas are required to have trash containers installed at the entrances/exits of the buildings. Bus shelters also include a 32-gallon trash container, which is emptied at least weekly.

Ojai – Performs field inspections, placement of no dumping signs, and clean up after public events, as part of the city permit process users are required to provide BMP and cleanup procedures.

Oxnard - The City of Oxnard utilizes the services of Oxnard City Corps to inspect and maintain the high priority catch basins. In September 2010, City Corps started using a small street sweeper/vacuum modified with a hose attachment to remove debris from the catch basins. The City of Oxnard owns and maintains two Fresh Creek trash removal devices located downstream of the high priority areas in the Wooley Road and Oxnard West Drains. The City of Oxnard has made a request to the County Watershed Protection District to install trash booms downstream of the high priority catch basins that flow into the J Street and Oxnard Industrial Drain.

Port Hueneme - Street sweeping goes beyond permit requirements. Solid Waste performs regular audits during their day to day services. The city is part of a joint effort with City of Oxnard that monitors and collects trash from the Oxnard West Drain. The city provides cleaning services and also supplies nets for the Fresh Creek device in the Oxnard West Drain. Areas where Priority A basins are located have full inlet screens and/or trash capture devices that were previously installed

Simi Valley - Identified the following high trash areas: pedestrian high traffic areas; restaurant concentration areas; special events. The city increased the number of trash receptacles in public areas prone to high amount of trash. The city has increased trash pickup to weekly or bi-weekly in public areas prone to high amount of trash.

Thousand Oaks - Trash cans at the MSC are emptied daily and roll off boxes containing scrap metal and greenwaste are covered with a tarp during inclement weather. Fifty-six public trash and recycling

containers are distributed at high trash areas, including high schools, California Lutheran University, the day labor site and other business, recreation and residential areas throughout the city where high foot traffic necessitates proper disposal options. A majority of these container are located near bus stops to meet the needs of both public transportation riders and pedestrians. All containers are serviced twice weekly by the city's franchised commercial solid waste hauler, Waste Management.

The MSC collects and recycles greenwaste, metal, antifreeze, motor oil and wheel weights. In addition to regular cleaning, clearing and sweeping the interior area of the MSC, all catch basins are cleaned regularly and include the use of a filter within each catch basin.

Ventura - Data collected from the cleaning of catch basins was used to determine the location of "high trash" generating areas. Those catch basins were designated "Priority A" catch basins and were fitted with trash excluder devices. In addition, other areas of the City were considered for the installation of trash excluders and at present over 100 devices have been installed. The City has gone out to bid for an additional 106 devices that will be installed by the end of the year. City staff regularly remove trash from right-of-way areas throughout the City. These include streets, medians, parkways, on and off ramps to freeways, walking and biking paths, and other public areas which may not otherwise receive litter abatement services. An average month requires over 100 "cleaning incidents" with significant amounts of litter and debris along public right-of-ways removed. Debris can include small objects such as cigarette butts or large items such as mattresses and couches. The City of Ventura has begun a "Safe and Clean" program that require City staff to participate in the cleanup of homeless encampments throughout the City. Trash receptacles throughout the City are emptied 1-5 times per week, depending on the location and the trash generated. The City trash contractor monitors and removes trash before it accumulates and overflows. In addition, bus shelters that have trash receptacles located nearby, are monitored and emptied daily if required. This last year the Ventura Pier was targeted for adding six recycle bins, six trash bins, and two fishing filament bins.

7.7.5 Trash Management at Public Events

Events in the public right of way, or wherever it is foreseeable that substantial quantities of trash and litter may be generated, require the following measures:

- Proper management of trash and litter generated

- Arrangement for temporary screens to be placed on catch basins
- Arrangement that trash is removed after the event

The Permittees appreciate having the ability to select the option that will work best in their jurisdiction and have employed several methods to ensure trash does not get into a storm drain after a public event. Most cities use the power of the Special Use Permit or Temporary Use Permit. With this they can, and do, require a trash and recycling management plan and/or a substantial deposit before issuing an event permit. Funds can be withheld if trash has not been properly managed and costs recovered and even fines levied if after the event staff is needed to clean up. A few agencies take on this responsibility and have street sweepers employed to clean streets of any trash immediately after a large event, or services the affected drains with a vacuum truck after the event has concluded.

Camarillo - Camarillo inspects the area after each public event held in public right-of-way and if trash is present, removes the debris. If a large quantity is left, the city withholds funds from the Special Use Permittee's deposit to cover expenses related to trash removal.

County of Ventura - All park facilities are equipped with trash containers that are checked and emptied on a daily basis. Additional containers are provided as required. Additional collection dates are scheduled if needed based on historical use patterns, site reservations, and field assessment by staff.

Airports Department added extra trash receptacles and dumpster bins. Also, Airports Department swept paved areas and increased litter and trash pick-ups.

Fillmore - Public events permits are required to have temporary trash receptacles and to pay for staff or to have a volunteer crew to clean trash during events. The Public Works Department also provides additional manpower for events that are designated City events.

Moorpark – Standard conditions for Temporary Use Permits (which include public events) include requirements for protection of the storm drain system from litter and other material. Proper trash management is required for the event and the nearby catch basins must be screened during the event.

Oxnard - Technical Services Program-Stormwater staff worked in conjunction with the Planning Division to revise the Temporary Use Permit Application. A "Drainage and Trash Management" requirement has been added as a condition for obtaining a TUP. Any applicant seeking a TUP for a public event where substantial quantities of trash may be generated must meet the above referenced conditions.

Ojai - As part of the city permit process permitted public events are required to provide BMP and cleanup procedures.

Port Hueneme - City staff vacuums out catch basins immediately after the events and also has the event host use BMPs such as placing fiber rolls in front of inlets during the course of the event.

Santa Paula - The city has increased the number of trash receptacles in public areas prone to high amounts of trash. The city schedules trash pickup immediately following public events.

Simi Valley – has created a trash management plan for public events which requires the event's responsible party to obtain a permit. This permit gives specific requirements for trash management at the event.

Thousand Oaks - Parking and storage areas are kept clean and orderly. Litter control at the MSC is managed by weekly sweeps of the facility grounds and by daily pick up of litter. The limited number of public events at the MSC include follow-up litter removal. City-sponsored public events, events charging admission fees and events attracting 2000+ participants are required to submit a Recycling Plan to ensure that proper solid waste management procedures are in place before the city will issue a Special Event Permit. Additionally, the City Environmental Programs division loans recycling containers to non-profit organizations free of charge for public events within the city.

Ventura - Most large public events are concentrated in the Downtown District. A total of 26 trash excluders were installed in the catch basins in this area. They are cleaned on the same schedule as the "Priority A" drains. The Downtown Organization employs personnel to clean up litter and other debris as part of their daily routine. The addition of one trash receptacle in the downtown mini-park and one trash receptacle on an additional street corner in the downtown, brings the total trash receptacles to 46 in the downtown..

7.7.6 Implement Storm Drain Maintenance Program

Permittees also routinely inspect and clean their drainage facilities during the year on an as-needed basis. "Routine cleaning" for these facilities, means the removal of accumulations of trash, sediment and debris likely be washed downstream with the next runoff event or cause a loss of hydraulic capacity and result in potential flooding.

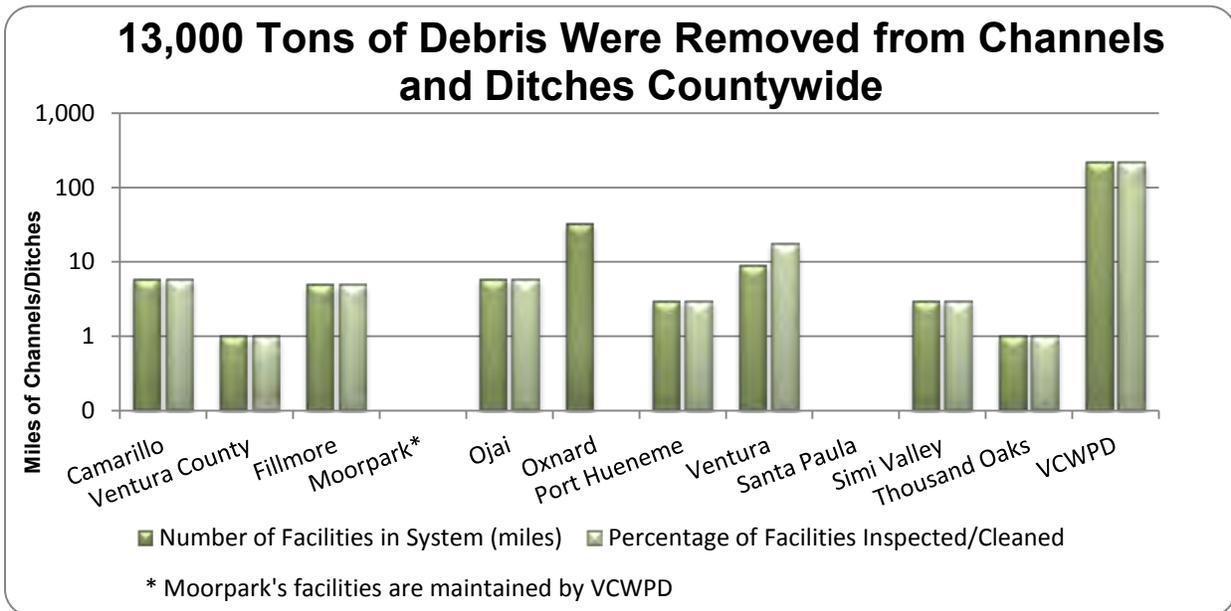

The Public Information and Participation section requires Permittees to have completed labeling or marking the curb inlets in their entire storm drain system, but the inspection and relabeling is required under Public Agencies. During the reporting period, some Permittees maintained their inlet signs by reapplying stencils/markers as they wore out and applying stencils/markers to new inlets as they were installed.

Performance Standard 7-12

Require appropriate litter control measures for public events			
	Yes	No	In Progress
Camarillo	<input checked="" type="checkbox"/>		
Ventura County	<input checked="" type="checkbox"/>		
Fillmore	<input checked="" type="checkbox"/>		
Moorpark	<input checked="" type="checkbox"/>		
Ojai	<input checked="" type="checkbox"/>		
Oxnard	<input checked="" type="checkbox"/>		
Port Hueneme	<input checked="" type="checkbox"/>		
Ventura	<input checked="" type="checkbox"/>		
Santa Paula	<input checked="" type="checkbox"/>		
Simi Valley	<input checked="" type="checkbox"/>		
Thousand Oaks	<input checked="" type="checkbox"/>		

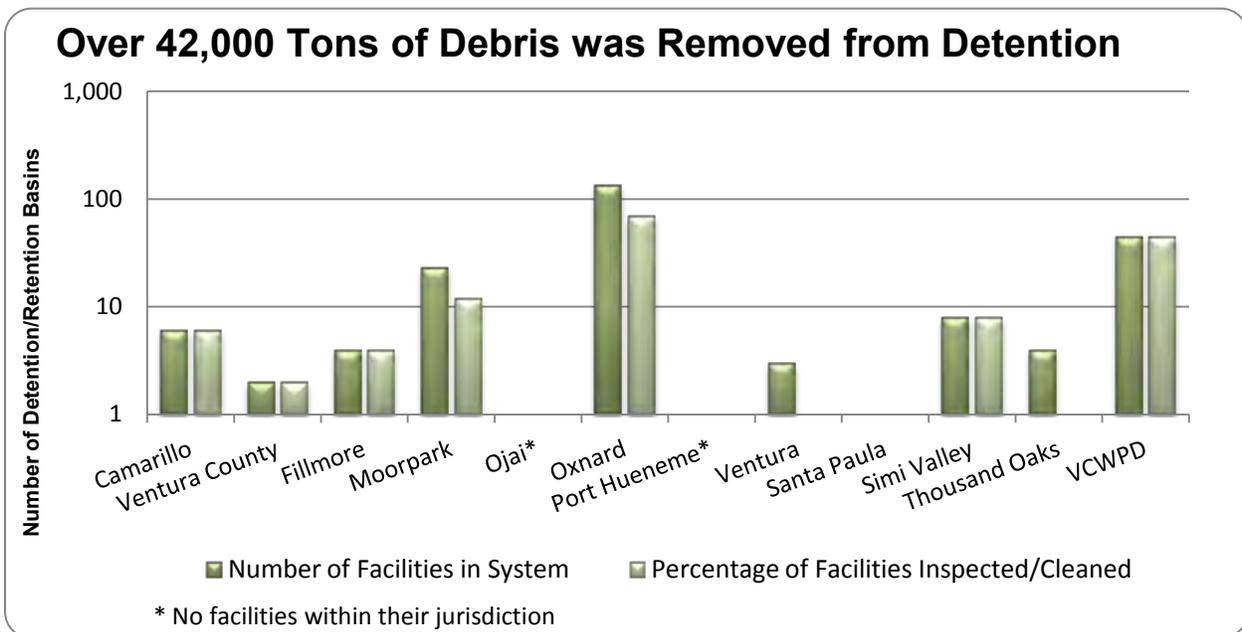

Signs at curb inlets have varying useful lives due to the materials from which they are constructed (e.g., paint or thermoplastic), their position (e.g., on top of curb or on curb face), and wear factors (e.g., traffic, street sweeping, sunlight). As a result, the Permittees have different programs to maintain curb inlet signage within their respective jurisdictions. Some Permittees replace a portion of their signs each year whereas others re-sign all inlets every few years. In the cases where a Permittee has a separate program for catch basin label maintenance from their catch basin debris maintenance program the catch basin debris maintenance inspection does not inspect for the label. Catch basin label data is reported in public outreach program.

Figure 7-8 Tons Removed from Channels and Ditches

When performing cleaning activities, Permittees implement appropriate BMPs to prevent sediments and debris from being washed downstream. By removing this amount of material from the catch basin inlets, open channels, and detention basins the Permittees prevent the passage of these materials to downstream receiving waters. During the reporting period, the Permittees tallied the collection of over 55,000 tons of solid debris from drainage facility maintenance activities.

Figure 7-9 Tons Removed from Detention Basins

7.7.7 Implement Spill Response Plan

Within their respective jurisdiction the Permittees implement a response plan for spills generated from their operations that have the potential to enter the MS4 system. Response plans include:

- Investigation of all complaints received within 24 hours of the incident report;
- Containment response within 2 hours to spills upon notification, except where such overflows occur on private property, in which case the response should be within 2 hours of gaining legal access to the property; and
- Notification to appropriate public health agencies and the Office of Emergency Services (OES).

Unfortunately, even with good training and well maintained equipment there are occasions where a spill or release will happen and need to be cleaned up. Cleanup can be as simple as dispatching a crew to pick up fallen debris, or a street sweeper or vacuum truck to clean an area or catch basin and storm drain after a known spill. It could also become a major multi-agency operation if hazardous materials are involved.

7.7.8 Inspect and Maintain Permittee-Owned Treatment Control BMPs

Permittees that own or are authorized to maintain treatment control BMPs have programs to implement an inspection and maintenance program for those treatment control BMPs, including post-construction treatment control BMPs. Private BMPs required for new development are managed in different ways. Some Permittees do not want to be responsible for the cleaning and maintenance of these BMPs and limit their role to inspection and enforcement to ensure effectiveness. Others will take on that responsibility on a case by case basis, and there are occasions where a Permittee has installed their own treatment BMPs to improve water quality.

When Permittees are performing maintenance of structural BMPs they implement their own BMPs to ensure that residual water produced by a treatment control BMP (not internal to the BMP performance) is:

- Hauled away and legally disposed of; or
- Applied to the land without runoff; or
- Discharged to the sanitary sewer system (with permits or authorization); or
- Treated or filtered to remove bacteria, sediments, nutrients, and meet all limitations

7.8 STREET AND ROADS MAINTENANCE – PA6

The Street and Roads Maintenance Control Measure ensures that the streets and roads are both cleaned to reduce pollutants and maintained in ways that prevent the release of pollutants..

7.8.1 Implement Street Sweeping Program

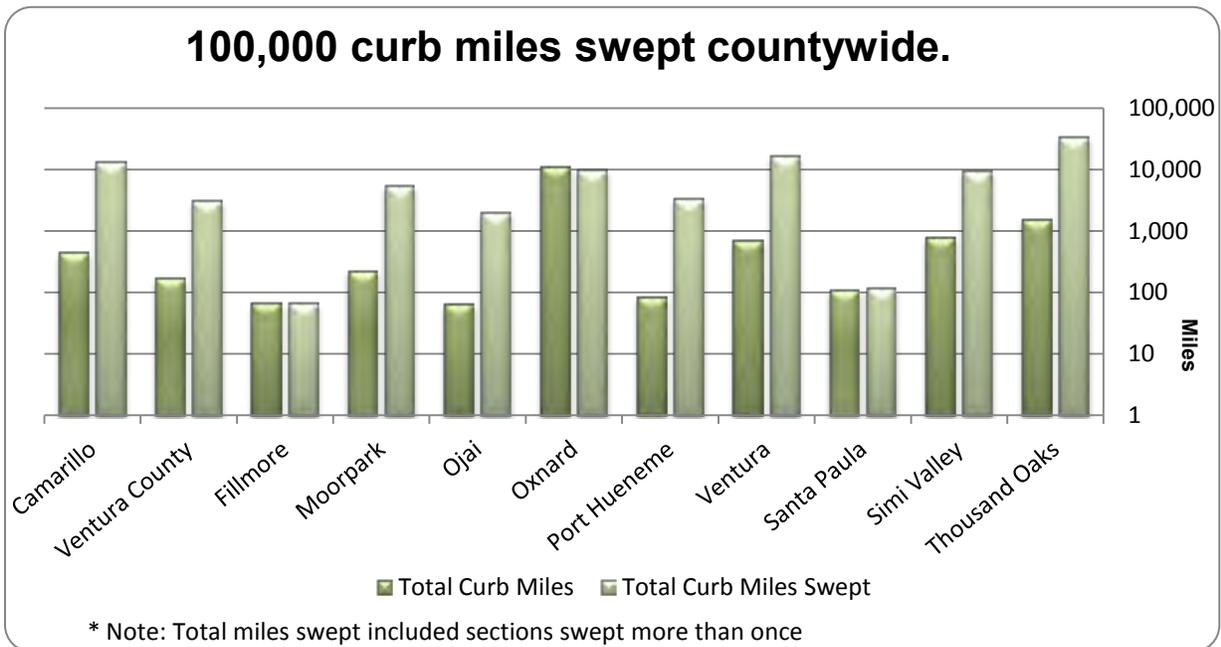

Permittees have identified curbed streets within their jurisdiction and have implemented a sweeping program for these streets. In many cases the frequency of street sweeping is beyond the permit requirement of at least twice a month for commercial areas and areas subject to high trash generation.

To increase the efficiency of the street sweeping, Permittees have made an effort to encourage voluntary relocation of street-parked vehicles on scheduled sweeping days. This has been achieved by placing temporary “no stopping” and “no parking” signs, posting permanent street sweeping signs and/or distributing street sweeping schedules to residents and businesses. Many of the Permittees have coordinated street sweeping to follow the routine trash collection days in order to remove any litter left in the streets by the trash removal service.

Performance Standard 7-13

Perform street sweeping of curbed streets in commercial areas and areas subject to high trash generation at least two times a month

7.8.2 BMP Implementation for Road Reconstruction Projects

For any road reconstruction project that includes roadbed or street paving, repaving, patching, digouts, or resurfacing road surfaces, the Permittees require that appropriate BMPs are implemented. The vast majority of this work falls under the definition of routine maintenance as the road will maintain the line and grade and original purpose of the facility. The implementation of these BMPs ensures the project will not impact stormwater without the need for a formal SWPPP or other documentation.

Performance Standard 7-14

Require that appropriate BMPs be implemented for any project that includes roadbed or street paving, repaving, patching, digouts, or resurfacing road surfaces

7.9 EMERGENCY PROCEDURES – PA7

The Emergency Procedures Control Measures ensures that each Permittee can conduct repairs of essential public service systems and infrastructure in emergency situations with a self-waiver. A self-waiver is required when there is a discharge to the storm drain system and the repairs needed to halt that discharge cannot be made within one day.

7.9.1 Invoke Emergency Procedures Self-Waiver

During the Permit term there was only one emergency that caused a Permittee to invoke Emergency Procedures Self-Waiver. The source was potable water, but the discharge was not dechlorinated and had the potential to mobilize pollutants. Self-Waivers invoked are reported here.

Table 7-3 Summary of Emergency Procedures

Summary of Emergency Procedures		
Permittee	Date Emergency	Description
Oxnard	9/15/2011	Main water line break at Perkins Road and Hueneme Road.

7.10 TRAINING – PA8

Training is important for the implementation of the Public Agency Activities Program Element. An effective training program is one of the best pollution prevention BMPs that can be implemented because it prompts behavioral changes that are fundamentally necessary to protect water quality.

Each Permittee targets staff based on the type of stormwater quality and pollution issues they typically encounter during the performance of their regular maintenance activities. Targeted staff included those who perform activities in the following areas: stormwater maintenance, drainage and flood control systems, streets and roads, parks and public landscaping, and corporation yards.

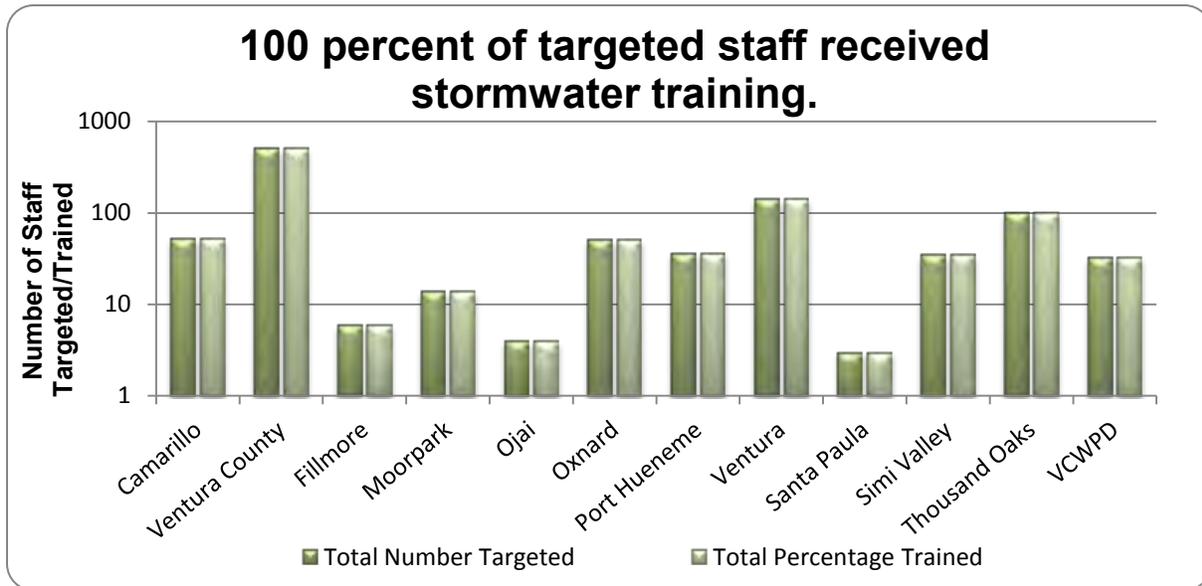

Performance Standard 7-15

Provide training, or ensure that contractors were trained, whose interactions, and activities affect stormwater quality			
	Yes	No	N/A
Camarillo	<input checked="" type="checkbox"/>		
Ventura County	<input checked="" type="checkbox"/>		
Fillmore	<input checked="" type="checkbox"/>		
Moorpark	<input checked="" type="checkbox"/>

Santa Paula	<input checked="" type="checkbox"/>		
Simi Valley	<input checked="" type="checkbox"/>		
Thousand Oaks	<input checked="" type="checkbox"/>		
Watershed Protection	<input checked="" type="checkbox"/>		

Training methods vary among Permittees and range from informal meetings to formal classroom training to self-guided training materials. The Permittees also train staff on the prevention, detection, and investigation of illicit discharges and illegal connections (IC/ID). (See Section 8 for more information regarding IC/ID training).

The Permittees provide training for contractors, or in some cases where contractors are hired for their expertise, to ensure that contractors hired had the required training, whose interactions, jobs, and activities affect stormwater quality. Not all employees receive the same training as certain positions require special focus, such as key staff that use or have the potential to use pesticides or fertilizers.

<ul style="list-style-type: none"> • Employees and contractors who use or have the potential to use pesticides and/or fertilizers 	<ul style="list-style-type: none"> • Potential for pesticide-related surface water toxicity • Proper use, handling, and disposal of pesticides • Least toxic methods of pest prevention and control, including IPM • Reduction of pesticide use
<ul style="list-style-type: none"> • Employees and contractors responsible for the IC/ID program 	<ul style="list-style-type: none"> • Cover the full IC/ID program from identification to enforcement.

7.11 EFFECTIVENESS ASSESSMENT – PA9

Effectiveness assessment is a fundamental component for developing and implementing successful stormwater programs. In order to determine the effectiveness of the Public Agency Activities Program, a comprehensive assessment of the program data is conducted as a part of the annual report. The results of this assessment are used to identify modifications that need to be made to the program. Each year the effectiveness assessment is reviewed and revised as needed.

By conducting these assessments and modifying the program as needed, the Permittees ensure that the iterative process is used as an effective management tool. Due to the types of data collected for the Public Agency Activities Program, current and future assessments will primarily focus on Outcome Levels 1-3.

- Outcome Level 1 (L1) answers the question: Did the Permittees implement the components of the Permit?

- Outcome Level 2 (L2) answers the question: Can the Permittees demonstrate that the control measure/performance standard significantly increased the awareness of a target audience?
- Outcome Level 4 (L4) answers the question: Can the Permittees demonstrate that the control measure/performance standard reduced the pollutant load?

The following is an assessment regarding the effectiveness of the Public Agency Program.

7.11.1 Public Construction Activities Management

Require Public Projects to Comply with Planning and Land Development and Construction Program Requirements

Where applicable, all Permittees require publically-owned or operated construction projects to comply with the Planning and Land Development and Construction Program requirements, or adopted standard practices for very small projects. (L1)

Require Development of SWPCP for Projects that Disturb less than 1 Acre

Grading or building permits are not an effective mechanism for identifying or defining small construction projects since they are not granted for public construction projects. Instead, all Permittees have effectively required small public projects to submit a SWPCP that identifies BMPs. (L1)

7.11.2 Vehicle Maintenance/ Material Storage Facilities/ Corporation Yard Management/ Municipal Operations

Implement Required BMPs for Each Facility

As indicated in table 7-2 Permittees have developed and implemented SWPCPs at all corporate yards. Inspections are performed annually and deficiencies are quickly corrected by Facility staff. (L1)

7.11.3 Vehicle and Equipment Wash Areas

Eliminate Wash Water Discharges

The majority of Permittees have successfully eliminated wash water discharges through a variety of options including offsite disposal, disposal to sanitary sewer, and treatment through clarifier. (L1) Discharges will continue to be eliminated as facilities are constructed, redeveloped or replaced.

7.11.4 Landscape, Park and Recreational Facilities Management

Implement IPM Program

The majority of Permittees have a draft IPM program that is consistent with the Permit. Further assessment is being conducted. (L1) (L2)

Maintain and Expand Internal Inventory on Pesticide Use

Permittees have effectively restricted the purchase and use of pesticides and herbicides to staff certified by the California Department of Food and Agriculture. Permittees that contract out for pesticide applications include standard protocols and requirements as a condition of the contract. (L1)

7.11.5 Storm Drain Operation and Management

Implement Storm Drain System Mapping

Since Ventura County's cities are all separated by open space and the MS4 from one city does not discharge to another, the need to integrate the maps into a countywide storm drain map is not as imperative as the need for a Permittee to be able to know what is upstream from any point in their MS4, and where that water will discharge. Given that the priority for the mapping is internal to the agency operating the system, the Permittees were given the autonomy to decide what form of mapping will work best for their needs.

Implement Catch Basin Maintenance Program

Each Permittee has identified criteria and a methodology for catch basin mapping and prioritization. More than 12,000 catch basins were cleaner during the Annual Reporting period. (L1) The Permittees have completed the process of designating and reporting debris removal by prioritization. During 2011/12, Permittees collectively removed more than 250,000 tons of debris from catch basins. (L4)

Install Trash Receptacles

The majority of Permittees have installed trash receptacles in high trash generation areas. Trash receptacles are cleaned out as necessary. (L1)

Install Additional Trash Management Devices

Permittees have begun the implementation of this performance standard. A more detailed assessment will be conducted once the deadline has passed (July 8, 2012).

Trash Management at Public Events

All Permittees have required trash management for any event in the public right-of-way. (L1) (L4)

Implement Storm Drain Maintenance Program

Each Permittee has a program to maintain curb inlet labeling. (L1) Additionally, all Permittees regularly maintain channels, ditches and detention basins. (L1) Implementation of this performance standard removed more than 23,000 tons of debris from channels and ditches and 98,000 tons of debris from detention basins countywide. (L4)

Implement Spill Response Plan

All Permittees maintain a spill response plan. (L1)

Inspect and Maintain Permittee-Owned Treatment Control BMPs

Permittees that own or are authorized to maintain treatment control BMPs have programs to implement an inspection and maintenance program for all Permittee-owned treatment control BMPs, including post-construction treatment control BMPs. (L1)

7.11.6 **Street and Roads Maintenance**

Implement Street Sweeping Program

Permittees have implemented a street sweeping program that at a minimum, targets commercial areas and high trash generation areas twice a month. More than 100,000 curb miles were swept countywide. (L1) (L4)

BMP Implementation Road Reconstruction Projects

All Permittees required BMPs for any road reconstruction project that includes roadbed or street paving, repaving, patching, digouts, or resurfacing. (L1)

7.11.7 **Emergency Procedures**

Invoke Emergency Procedures

One Permittee had an emergency that required Permittees to invoke Emergency Procedures. (L1)

7.11.8 **Training**

Conduct Training

Permittees provided training for 100% of targeted staff. Over 1000 staff were trained on the implementation of BMPs, reduction of pesticide use, and reduction of illicit connections/illicit discharges. (L1)

7.12 PUBLIC AGENCY ACTIVITIES PROGRAM MODIFICATIONS

On an annual basis, the Permittees plan to evaluate the results of the Annual Report, as well as the experience that staff has had in implementing the program, to determine if any additional program modifications are necessary to comply with the Clean Water Act requirement to reduce the discharge of pollutants to the MEP. Any key modifications made to the Public Agency Program Element during the next fiscal year will be reported in the following Annual Report.

8 Illicit Connections and Illicit Discharges Elimination

8.1 OVERVIEW

Illicit connections and illicit discharges (IC/ID) can be concentrated sources of pollutants to municipal storm drain systems. To reduce this source of pollutants the Permittees have developed and implemented programs for the identification and elimination of IC/ID to the MS4. Key components of these programs are public reporting, field screening, incidence response, and enforcement actions.

The Permittees have developed and implemented programs for the identification and elimination of illicit connections and illicit discharges to the municipal separate stormwater sewer system (MS4).

The term “illicit discharges” used in this program is any discharge to the storm drain system that is prohibited under local, state or federal ordinances. The term includes all discharges not composed entirely of stormwater except discharges allowed under an NPDES permit. Examples of illicit discharges include:

- Incidental spills, or disposal of wastes and non-stormwater. These may be intentional, unintentional, or accidental and would typically enter the storm drain system directly through drain inlets, and catch basins;
- Discharges of sanitary sewage due to overflows or leaks;
- Discharges of prohibited non-stormwater other than through an illicit connection. These typically occur as surface runoff from outside the public right-of-way (e.g., area washdown from an industrial site).

Categories of non-stormwater discharges not prohibited (exempted or conditionally exempted) under the Permit are listed below.

- Stream diversions permitted by the State Board
- Natural springs and rising groundwater
- Uncontaminated groundwater infiltration [as defined by 40 CFR 35.2005(20)]
- Flows from riparian habitats of wetlands
- Discharges from potable water sources
- Drains for foundation, footing and crawl drains
- Air conditioning condensate
- Water from crawl space pumps
- Reclaimed and potable landscape irrigation runoff
- Dechlorinated/debrominated swimming pool discharges
- Non-commercial car washing by residents or non-profit organizations
- Sidewalk rinsing
- Pooled stormwater from treatment BMPs

Accidents are inevitable, so it will be impossible to eliminate all illicit discharges. Just as police cannot eliminate all crime in a community, unfortunately, there will always be an element of society that will contribute to the problem. However, through the combined efforts of the public education, business inspection, construction inspection, and illicit discharge programs the preventable acts of willfully using the storm drain system to dispose of waste will be kept to a minimum.

Illicit connections, while sometimes done in error, cannot be considered accidents. An illicit connection to the storm drain system is an undocumented and/or un-permitted physical connection from a facility or

fixture to the storm drain system. Finding and eliminating illicit connections requires ongoing investigation and screening efforts.

8.2 CONTROL MEASURES

The Permittees have developed several Control Measures and accompanying performance standards to ensure that the Illicit Discharges/Connections Program requirements found in the Permit are met and information provided for optimizing the Program.

The Illicit Discharges/Connections Program Control Measures are organized the same as in the Permit and consist of the following:

Table 8-1 Control Measures for the Illicit Discharges/Connections Program Element

ID	Control Measure
ID1	Detection of Illicit Discharges and Illicit Connections
ID2	Illicit Discharge and Illicit Connection Response and Elimination
ID3	Training
ID4	Effectiveness Assessment

At the end of this chapter these control measures are evaluated to determine the effectiveness of this program element.

8.3 DETECTION OF ILLICIT CONNECTIONS AND ILLICIT DISCHARGES – ID1

Detection of IC/ID through public awareness, the availability of a public hotline, and conducting illicit connection screening ensures that the IC/ID Program is proactive in identifying and eliminating problematic discharges. This control measure reflects the Permittee’s efforts to detect and eliminate IC/ID and provides several mechanisms for collecting information.

The Permittees have a number of programs supporting the detection of IC/ID. These programs include:

- Industrial and commercial facility site visits (outlined in Section 2: Industrial/Commercial Facilities Program)
- Public education materials (outlined in Section 3: Public Outreach)
- Drainage facility inspection (see Section 5: Public Agency Activities)
- Construction inspections and BMP implementation (outlined in Section 6: Development Construction)
- Water quality monitoring (detailed in Section 9: Monitoring and Reporting Program)

The performance standards for this IC/ID control measure and the activities that have been initiated and/or completed during this reporting period are summarized below.

8.3.1 Public Reporting

The Public Outreach Program control measures (See Section 3) detail the methods by which the Permittees educate the community about stormwater pollution. Part of this outreach is information about

the IC/ID Program and part is reporting of IC/ID when observed. For the first few years, as the Stormwater Program evolved and the public became aware of what was not allowed down storm drains, reports of IC/ID increased; however, for the last six years reports of IC/ID have demonstrated a decreasing trend. Since the public is more aware of IC/ID this decrease likely represents a change in behavior and fewer pollutants are reaching the storm drains.

Since the public are the eyes of the IC/ID program, many illicit discharges are identified through public reporting of the situation. The goal of this component, in tandem with the Public Outreach component, is to educate the public and facilitate public reporting of illicit discharges and illicit connections. The baseline objectives are:

- Implement a program to receive calls from the public regarding potential illicit discharges and illicit connections, communicate and coordinate a timely response, perform all necessary follow up to the complaint, and maintain documentation.
- Provide educational material on non-stormwater discharges and why they are harmful to streams, and oceans and how to report them;
- Target the land development/construction community with educational material and provide workshops on stormwater quality regulations and illicit discharge prevention response; and
- Target the industrial/commercial community with educational material and provide workshops on stormwater quality regulations and illicit discharge prevention and response.

8.3.2 Publication of IC/ID Program Procedures

As part of the IC/ID outreach effort, the Permittees have documented their IC/ID Program through past Annual Reports which are available for public review at the Program’s web site (www.vcstormwater.org). This is one means by which interested individuals can educate themselves on what constitutes IC/ID and how to report it. More directly, however, the program promotes the reporting of illicit discharges through the Public Information and Public Participation Program.

8.3.3 Public Reporting

Public reporting is one of the most important ways that the public can help prevent the discharge of pollutants from IC/ID. Each Permittee has identified staff serving as the contact person(s) for public reporting of IC/ID, as discussed further in Public Outreach Control Measures (See Section 3). As required by the Permit Permittees maintain a phone hotline to receive reports of IC/ID. Due to the need for timely response to illicit discharges by

inspectors the web sites direct people to report by telephone to a “live person” instead of through email which, while quickly delivered, may not be read within the short time frame that a discharge is occurring.

The Program maintains a website that contains the phone numbers for all the Permittees. This information is updated as necessary and, as required in the Permit, published in the government pages of the local phone book and other appropriate locations. A list of hotlines are presented in Table 8-2 .

Timely responses to reports of illicit discharges are necessary to have the opportunity to determine the source, identify the responsible party, and have them initiate any cleanup to reduce pollutants from such discharge to the MEP. The baseline objectives include:

- Initiate response within 24 hours of receiving a report of discharge from the public, other agencies or observed by a Permittee field staff during the course of their normal daily activities;
- Investigate to determine the nature and source of discharge and eliminate through voluntary termination (when possible) or enforcement action; and
- Educate identified responsible parties and initiate clean up and enforcement actions as necessary.

While the goal is to respond within 24 hours, most reports of illicit discharges are responded to within a few hours. Some Permittees have prioritized problem areas (geographical and/or activity-related) for increased inspections using the methods defined in the program. All illicit discharges reported by the public and found through the results of inspections are presented in Figure 8-1.

Figure 8-1 Illicit Discharge Investigations

8.3.4 IC/ID Tracking

Tracking the location of illicit connections and illicit discharge, aside from being a Permit requirement is assumed to assist the Program’s efforts understanding which land uses, age of neighborhood or other potential identifier is common to the problem of illicit discharges and connections. That knowledge could be useful in the future as the Public Outreach and Business Inspections programs continue to evolve.

Performance Standard 8-4

Keep records of all illicit discharge discoveries, reports, responses, and formal enforcement

Mapping of Known Connections to Storm Drain System

The benefit of mapping all storm drain connections is to allow the Permittees the ability to know the upstream location of an unknown, and conversely what might be possibly affected downstream. This is required in the Permit by May 7, 2012. Since the storm drain system includes all streets and gutters, literally mapping all known connections would include every driveway and property that drains to a street. Since an endeavor of that scale would be resource intensive and with an end product that will lack practical usability, the Permittees have looked to the Regional Board for clarification of the requirement. In the response to comments on this topic the Regional Board provided the following statement: “*Known connections in the Order refer to permitted below grade*”

Mapping connections in the field

connections whose locations are likely already known to Permittees. Staff agrees that mapping may reveal additional connections, but those are likely to be un-permitted.” This guidance creates a manageable effort and ultimately a useful product that will increase the Permittees ability to respond to IC/IDs.

Mapping Illicit Connection and Discharge Incidents

The Permit requires the mapping of all incidents of illicit connections and illicit discharges to their storm drain system since January 2009 by May 7, 2012 at a scale and in a format specified by the Principal Permittee.

Using this requirement to identify priority areas for further investigation and elimination of IC/ID, the Permittees mapped all known connections to their storm drain system and all IC/ID incidents by July 8, 2012, outside of the reporting period for this report. While no obvious hotspots jumped out while reviewing the maps, the discharges were plotted on GIS and compared to other data layers to identify any consistent correlations that could be used to focus resources to prevent illicit discharges before they contribute to stormwater pollution. Figures 8-3 shows the illicit discharges by land use. Residential areas by far have the highest number of illicit discharges, but they are also the largest areas of the cities. When normalized for area commercial land uses become the major source of illicit discharges. This was not a surprise to the Permittees. By their nature commercial areas have lots of activity and high visibility, discharges in those areas have a high chance of being reported by residents or neighbors who do not want the mess near their business. Overall nothing new was learned about illicit discharges through the mapping exercise. The Permittees have learned through experience which areas have problems with illicit discharges, and have strong inspection programs to prevent them.

Figure 8-2

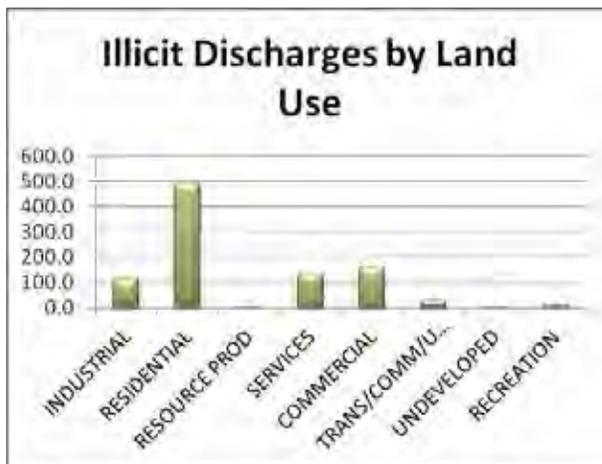

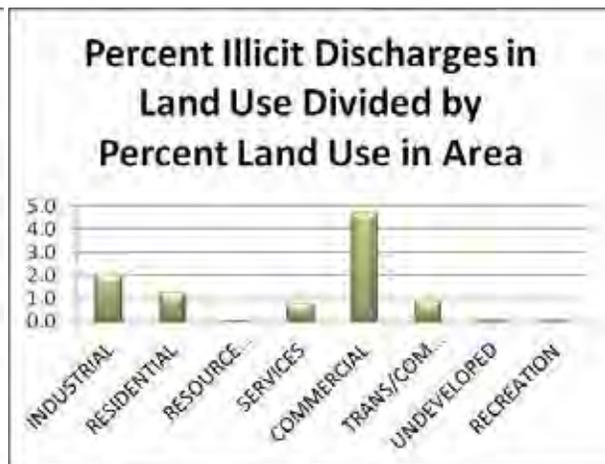

Figure 8-3

8.3.5 Screening for Illicit Connections

Inspections of infrastructure can detect and eliminate illicit connections to the MS4 and reduce pollutants discharged through such connections to the MEP. The objectives of illicit connections screening are to:

- Inspect the storm drain system to identify illicit connections during scheduled infrastructure maintenance by personnel

- Investigate and determine the origin and nature of the discharge when connections to the storm drain system are suspected or observed to be a source of an illicit discharge

Mapping of Storm Drain System

Similar to mapping requirements of known connections to the storm drain system the Permit requires mapping of the entire system in a phased approach outlined below.

- Map all channeled portions of the storm drain system by October 6, 2010
- Map all portions of the storm drain system consisting of pipes 36 inches in diameter or greater by May 7, 2012
- Map of all portions of the storm drain system consisting of pipes 18 inches in diameter or greater by May 7, 2014

Performance Standard 8-5

Submit a map of all channeled portions of the storm drain system in a uniform format			
	Yes	No	In Progress
Camarillo	<input checked="" type="checkbox"/>		
Ventura County	<input checked="" type="checkbox"/>		
Fillmore	<input checked="" type="checkbox"/>		
Moorpark	<input checked="" type="checkbox"/>		
Ojai	<input checked="" type="checkbox"/>		
Oxnard	<input checked="" type="checkbox"/>		
Port Hueneme	<input checked="" type="checkbox"/>		
Ventura	<input checked="" type="checkbox"/>		
Santa Paula	<input checked="" type="checkbox"/>		
Simi Valley	<input checked="" type="checkbox"/>		
Thousand Oaks	<input checked="" type="checkbox"/>		
Watershed Protection	<input checked="" type="checkbox"/>		

Performance Standard 8-6

Submit to the Principal permitted a map of all portions of the storm drain system consisting of pipes 36 inches in diameter or greater in a uniform format			
	Yes	No	In Progress
Camarillo	<input checked="" type="checkbox"/>		
Ventura County	<input checked="" type="checkbox"/>		
Fillmore		<input checked="" type="checkbox"/>	
Moorpark	<input checked="" type="checkbox"/>		
Ojai	<input checked="" type="checkbox"/>		
Oxnard	<input checked="" type="checkbox"/>		
Port Hueneme		<input checked="" type="checkbox"/>	
Ventura	<input checked="" type="checkbox"/>		
Santa Paula	<input checked="" type="checkbox"/>		
Simi Valley	<input checked="" type="checkbox"/>		
Thousand Oaks	<input checked="" type="checkbox"/>		
Watershed Protection	<input checked="" type="checkbox"/>		

Performance Standard 8-7

Submit map of all portions of the storm drain system consisting of pipes 18 inches in diameter or greater in a uniform format? (Due by May 7, 2014)			
	Yes	No	In Progress
Camarillo	<input checked="" type="checkbox"/>		
Ventura County	<input checked="" type="checkbox"/>		
Fillmore		<input checked="" type="checkbox"/>	
Moorpark	<input checked="" type="checkbox"/>		
Ojai	<input checked="" type="checkbox"/>		
Oxnard	<input checked="" type="checkbox"/>		
Port Hueneme			<input checked="" type="checkbox"/>
Ventura	<input checked="" type="checkbox"/>		
Santa Paula	<input checked="" type="checkbox"/>		
Simi Valley	<input checked="" type="checkbox"/>		
Thousand Oaks	<input checked="" type="checkbox"/>		
Watershed Protection	<input checked="" type="checkbox"/>		

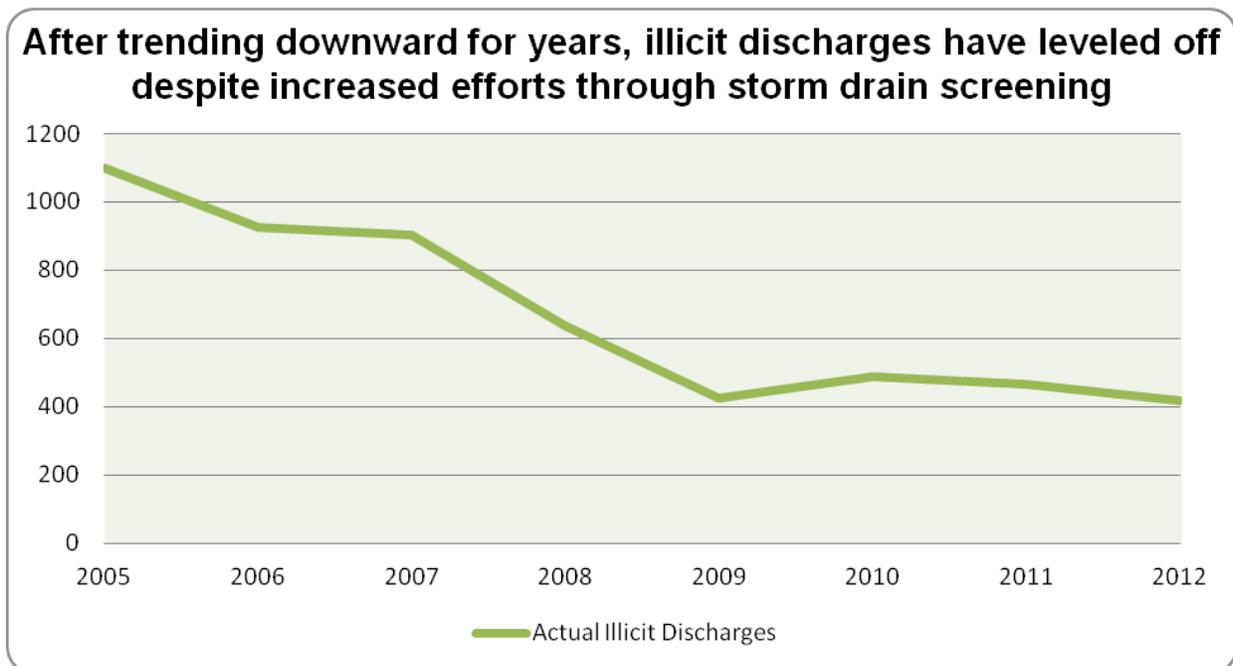

To assist in screening for illicit connections, the Permittees have mapped channels within their permitted area and the storm drain system. These maps were transmitted to the Principal Permittee and are in the process of being incorporated into the Watershed Protection District's GIS system. This incorporation may be as simple as having scanned drawings available through the GIS system when no true GIS data exists. Maps depicting the storm drain system consisting were completed by May 7, 2012 and those 18 inches or greater will be completed by May 7, 2014.

Field Screening

The Permittees have developed an IC/ID Field Screening Protocol using the guidance from the “Illicit Discharge Detection and Elimination, A Guidance Manual for Program Development and Technical Assessments”². This document is included as Attachment D and suggests that field screening consist of:

- Progressive sampling of manholes to isolate IC/ID to specific sections of the storm drain system (e.g., sampling progressively up the storm drain trunk from an outfall)
- Based on a specific indicator in IC/ID and land use of drainage area, survey of suspected generating sites within the drainage area and on-site testing (e.g., based on sudsy discharge and commercial drainage area, investigation of drainage area to identify laundromats and conduct on-site testing would be warranted)
- Tracking ID/IC to a pipe section of the storm drain system through video or smoke testing.
- Septic system inspections through homeowner surveys, surface inspections, or infrared photography (e.g., Inspect area above septic system for foul odors, wet ground)

Figure 8-4 Illicit Discharge Trends

²*Illicit Discharge Detection and Elimination, A Guidance Manual for Program Development and Technical Assessments*. The Center for Watershed Protection, Pitt R., October 2004. Chapter 13, 13.1,13.2, 13.3, 13.4

As discussed previously in this section, the Permittees have begun to map the storm drain system in order to identify high priority areas for inspection. The Permittees inspected the storm drain system based on these maps, and report illicit connections to the Regional Water Board. The screening effort did not identify a high number of illicit discharges, this can be seen in Figure 8-4 that displays the trend of actual illicit discharges countywide. The reduction seen in illicit discharges can be seen as a change of behavior as the public gains knowledge of stormwater pollution. The field screening may have identified a few discharges, but public reporting remains the most efficient way to identify them. The requirements for screening were during the reporting period and are outlined below.

- Screen all portions of the storm drain system consisting of pipes 36 inches in diameter or greater by May 7, 2012
- Screen all high priority areas identified during the mapping of illicit connections and discharges by May 7, 2012
- Screen all portions of the storm drain system 50 years of age or older by May 7, 2012

Performance Standard 8-8

8.4 ILLICIT DISCHARGE/CONNECTION INVESTIGATION AND ELIMINATION – ID2

Timely investigations of reports of IC/ID are necessary to have the opportunity to determine the source, identify the responsible party and initiate any cleanup to reduce pollutants from such discharge to the MEP. This reporting year, the Permittees continued to:

- Investigate the cause, determine the nature, and estimate the amount of discharge for each reported illicit discharge/dumping incident;
- Determine when possible the type of materials and source type for each reported illicit discharge/dumping incidents;
- Determine when possible the probable cause for the illicit discharge/dumping;
- Conduct enforcement or educational activities to prevent similar discharges from reoccurring;
- Verify that reported illicit discharge/dumping incidents were terminated and/or cleaned up;
- Refer illicit discharge/dumping or illicit connections to other agencies when appropriate;
- Identify and eliminate illicit connections;
- Provide educational materials and contact numbers for reporting illicit discharge/dumping when conducting stormwater inspections.

Performance Standard 8-11

Thousand Oaks	<input checked="" type="checkbox"/>		
Watershed Protection	<input checked="" type="checkbox"/>		

8.4.1 Legal authority

Although adequate legal authority existed for most potential pollutant discharges at the inception of the stormwater program in 1994, the Permittees determined for the first stormwater ordinance a Model Stormwater Quality Ordinance should be developed to provide a more uniform countywide approach and to provide a legal underpinning to the entire Ventura Countywide NPDES Stormwater Program.

Subsequently, all of the Permittees adopted largely similar versions of the model Stormwater Quality Ordinance. In addition, each Permittee has designated Authorized Inspector(s) responsible for enforcing the Ordinance. The Authorized Inspector(s) is the person designated to investigate compliance with, detect violations of and/or take actions pursuant to the Ordinance. These ordinances prohibit un-permitted discharges, and provide the Permittees with legal standing and legal authority to prevent and remove

illicit connections and illicit discharges. A Stormwater Quality Ordinance has been adopted in each Permittees' jurisdictions as indicated in Table 8-3.

Performance Standard 8-13

Take appropriate enforcement action to eliminate the illicit discharge			
	Yes	No	N/A
Camarillo	<input checked="" type="checkbox"/>

Thousand Oaks	<input checked="" type="checkbox"/>		
Watershed Protection	<input checked="" type="checkbox"/>		

8.4.2 Response to Illicit Connections

Investigation

Each Permittee detects and eliminates illicit connections within its municipal storm drain system. Any illicit connection identified by the Permittees during routine inspections or reported by a third party is investigated. Appropriate actions are then taken to approve undocumented connections by permit procedure or pursue removal of those connections determined to be illicit connections and therefore not permissible.

Performance Standard 8-15

Maintain a list of all connections under investigation for possible illicit connection and their status			
	Yes	No	N/A
Camarillo	<input checked="" type="checkbox"/>		
Ventura County	<input checked="" type="checkbox"/>		
Fillmore	<input checked="" type="checkbox"/>		
Moorpark	<input checked="" type="checkbox"/>		
Ojai	<input checked="" type="checkbox"/>		
Oxnard	<input checked="" type="checkbox"/>		
Port Hueneme			<input checked="" type="checkbox"/>
Ventura	<input checked="" type="checkbox"/>		
Santa Paula		<input checked="" type="checkbox"/>	
Simi Valley	<input checked="" type="checkbox"/>		
Thousand Oaks	<input checked="" type="checkbox"/>		
Watershed Protection	<input checked="" type="checkbox"/>		

If the discharge from an identified connection is determined to consist only of stormwater or exempted non-stormwater, the connection will be allowed to remain and will no longer be considered an illicit connection. Permittees may elect to issue a permit for the connection or allow the connection to remain if information on the connection is documented; or the discharge will be permitted through a separate NPDES permit; if not the connection will be terminated through voluntary action or enforcement proceedings.

Screening has been implemented by the Permittees and has proven to be a very labor intensive effort resulting in very few suspect connections turning out to be illicit connections that need to be terminated. Of the 139 possible illicit

connections only 26 were identified as actual unpermitted illicit connections, and as of this report 4 were terminated. Termination or formal enforcement of illicit connections must occur within 180 days.

Each of the Permittee also maintains a record of all connections currently under investigation for possible illicit discharge and tracks their status.

Performance Standard 8-16

Complete investigation of reports of illicit connections to determine the source, nature, and volume of the discharge as well as the responsible party within 21 days			
	Yes	No	N/A
Camarillo	<input checked="" type="checkbox"/>		
Ventura County	<input checked="" type="checkbox"/>		
Fillmore	<input checked="" type="checkbox"/>		
Moorpark	<input checked="" type="checkbox"/>		
Ojai	<input checked="" type="checkbox"/>		
Oxnard	<input checked="" type="checkbox"/>		
Port Hueneme			<input checked="" type="checkbox"/>
Ventura	<input checked="" type="checkbox"/>		
Santa Paula	<input checked="" type="checkbox"/>		
Simi Valley	<input checked="" type="checkbox"/>		
Thousand Oaks	<input checked="" type="checkbox"/>		
Watershed Protection	<input checked="" type="checkbox"/>		

The response time to an illicit connection is included in the Permittees' IC/ID database and does not exceed 21 days. The source, nature, and type of discharges from these connections as well as the responsible party are also documented in the Permittees' IC/ID database. Summary statistics of the source of the illicit discharge from these connections is grouped with all other illicit discharges.

Performance Standard 8-17

Terminate the connection using formal enforcement within 180 days of completion of the investigation			
	Yes	No	In Progress
Camarillo	<input checked="" type="checkbox"/>		
Ventura County			<input checked="" type="checkbox"/>
Fillmore		<input checked="" type="checkbox"/>	
Moorpark	<input checked="" type="checkbox"/>		
Ojai		<input checked="" type="checkbox"/>	
Oxnard	<input checked="" type="checkbox"/>		
Port Hueneme			<input checked="" type="checkbox"/>
Ventura	<input checked="" type="checkbox"/>		
Santa Paula		<input checked="" type="checkbox"/>	
Simi Valley	<input checked="" type="checkbox"/>		
Thousand Oaks	<input checked="" type="checkbox"/>		
Watershed Protection	<input checked="" type="checkbox"/>		

Termination

The Permit requires the connection be terminated within 180 days of completion of the investigation. Upon confirmation of an illicit connection, the Permittees terminate the connection using formal enforcement within 180 days of completion of the investigation.

Performance Standard 8-18

Documentation

The Permittees' IC/ID database documents the time by which the illicit connection is terminated. Owners of existing drains without appropriate permits (including encroachment permits) are notified to comply. For those drains where the owner is unresponsive or cannot be identified, each Permittee is responsible for deciding whether to formally accept the connection as part of their public drainage system or cap it off.

Keep records of all illicit connection investigations and formal actions taken to eliminate all illicit connections			
	Yes	No	N/A
Camarillo	<input checked="" type="checkbox"/>		
Ventura County	<input checked="" type="checkbox"/>		
Fillmore	<input checked="" type="checkbox"/>		
Moorpark	<input checked="" type="checkbox"/>		
Ojai	<input checked="" type="checkbox"/>		
Oxnard	<input checked="" type="checkbox"/>		
Port Hueneme			<input checked="" type="checkbox"/>
Ventura	<input checked="" type="checkbox"/>		
Santa Paula	<input checked="" type="checkbox"/>		
Simi Valley	<input checked="" type="checkbox"/>		
Thousand Oaks	<input checked="" type="checkbox"/>		
Watershed Protection	<input checked="" type="checkbox"/>		

Upon receipt of a complaint, the Permittees investigate the source and nature of the IC/ID with the goals of:

- Eliminating the IC/ID through voluntary termination or enforcement action (when possible)
- Educating identified responsible parties and initiating enforcement actions as necessary

Investigation and Cleanup

Timely responses to reports of illicit discharges are necessary to have the opportunity to determine the source, identify the responsible party and initiate any necessary cleanup to reduce pollutants from such discharge to the MEP. The baseline objectives include:

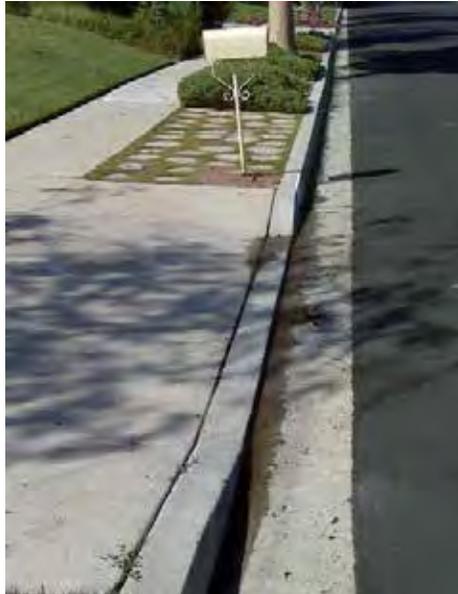

- Initiate response within 24 hours of receiving a report of discharge from the public, other agencies or observed by a Permittee field staff during the course of their normal daily activities;
- Investigate to determine the nature and source of discharge and eliminate through voluntary termination (when possible) or enforcement action; and

- Educate identified responsible parties and initiate enforcement actions as necessary.

While the goal is to respond within 24 hours, most reports of illicit discharge are responded to within a

Evidence of an illicit discharge

Pollutants removed after cleanup

few hours. Some Permittees have prioritized problem areas (geographical and/or activity-related) for inspection, cleanup and enforcement using the methods defined in the program. In the normal course of an investigation the responsible party will be directed to perform any possible clean-up. 100% of illicit discharges were investigated and 100% of confirmed illicit discharges were resolved.

The discovery of potential or likely illicit discharges through business inspections has worked to reduce the number of overall illicit discharges. Inspections of infrastructure can also detect and eliminate illicit connections to the MS4 and reduce pollutants discharged through such connections to the MEP. The baseline objectives include:

- Inspect the storm drain system to identify illicit connections during scheduled infrastructure maintenance by personnel
- Connections to the storm drain system that are suspected or observed to be a source of an illicit discharge will be investigated to determine the origin and nature of the discharge
- Use business inspections to identify and resolve potential illicit discharges and illicit connections; and
- Educate the business community on the environmental and legal consequences of illicit discharges.

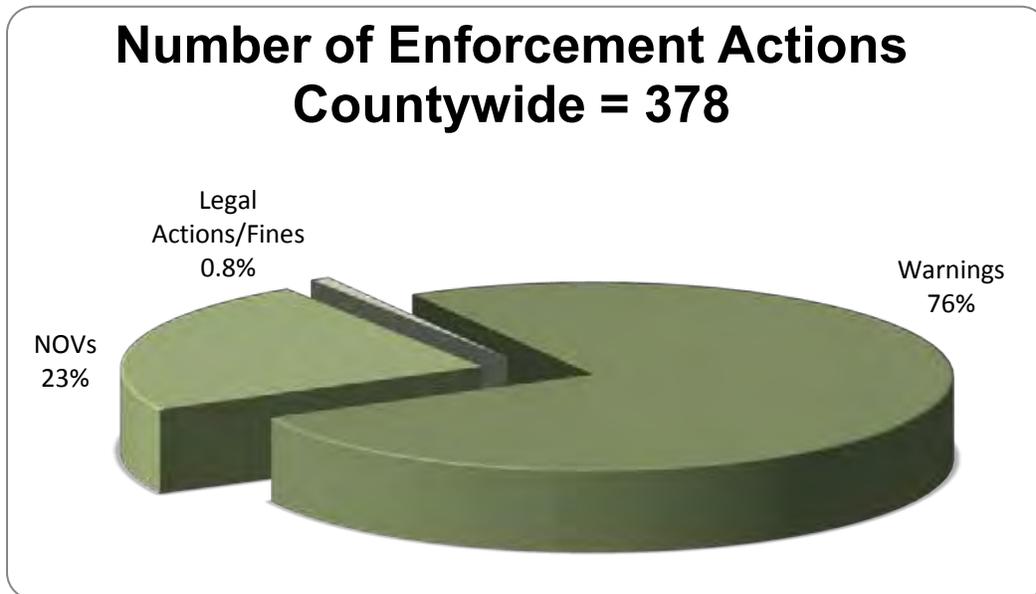

While the goal is to respond to illicit discharges reports within 24 hours, most reports are responded to within a few hours.

Enforcement

Permittees continue to implement enforcement procedures to eliminate illicit discharges and illicit connections available through their legal authority of their respective ordinances. Most enforcement processes follow a common sequence. These typically include:

- Verbal or written warnings for minor violation
- Formal notice of violation or non-compliance with compliance actions and time frames
- Cease and desist or similar order to comply
- Specific remedies such as civil penalties (e.g., infraction), non-voluntary termination with cost recovery, referral for criminal penalties, or further legal action
- Authority to issue civil citations of \$100 on site

Figure 8-5 Enforcement Actions Countywide

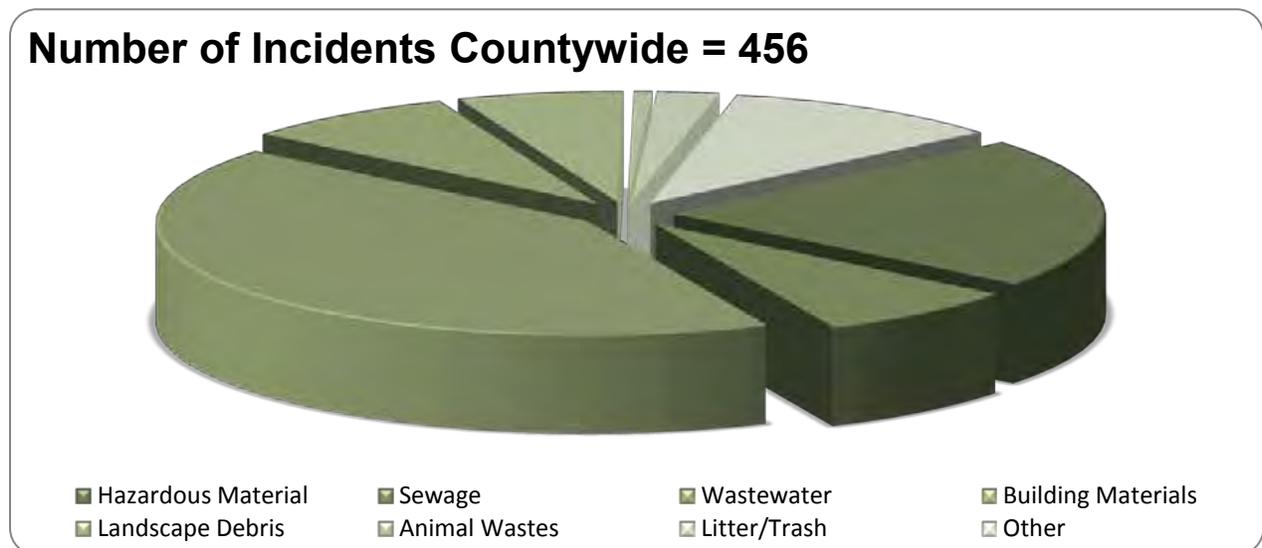

Every time a responsible party is identified for an illicit discharge there is an opportunity for education and enforcement. Enforcement activity begins at the appropriate level as determined by the Permittees' authorized representative. For incidents more severe or threatening at the onset, enforcement starts at an increased level. Often times a verbal warning and requiring cleanup of the discharge is effective, if necessary the Permittee will charge the responsible party for cleanup services provided. Enforcement steps are accelerated if there is evidence of a clear failure to act or an increase in the severity of the discharge. Enforcement actions for violating any of the provisions of the Permittees' ordinances may include any of the following or a combination thereof:

- Criminal Penalties
- Monetary punishment
- Imprisonment
- Civil Penalties

Education of targeted audiences occurs through inspections of illicit discharges, businesses, and construction activities. The importance of eliminating or mitigating non-stormwater discharges to local streams and channels is emphasized.

The capacity to issue civil citations has been added to the City of Oxnard’s enforcement plan to ensure that repeat violators of local, state, and federal stormwater quality regulations are assessed a fine for their illicit (illegal) activities. The integration of this enforcement action allows the municipality to assess a \$100.00 fee for those individuals or entities that receive a notice of violation (NOV) and thereafter again engage in the same illicit discharge activity. An additional \$100.00 fine is assessed, per day and per violation, if a repeat violation is committed within a thirty (30) day period. If, after thirty (30) days, the same party is once again engaging in similar illicit activities then a \$200.00 citation is given. A \$500.00 fine is issued to third time participants of an illicit discharge committed within sixty (60) days after the initial citation. Since current City policy allows the Mayor to delegate the authority to issue civil citations to designated employees, no changes to the City’s stormwater ordinance were necessary. The only prerequisite imposed on these employees was that they receive training on civil citation writing from the City of Oxnard Code Enforcement Unit. Simply having the ability, and threat, to issue a civil citation has proven to be enough of a deterrent to discourage/eliminate future occurrences of the same type of illicit activities from the local residents and the construction/building communities.

Figure 8-6 Illicit Discharges Incidents

Documentation

Permittees keep records of all illicit discharge discoveries, reports, responses, and enforcement and track the efforts during the permit term in the Permittees' IC/ID database and summarized in the figures below.

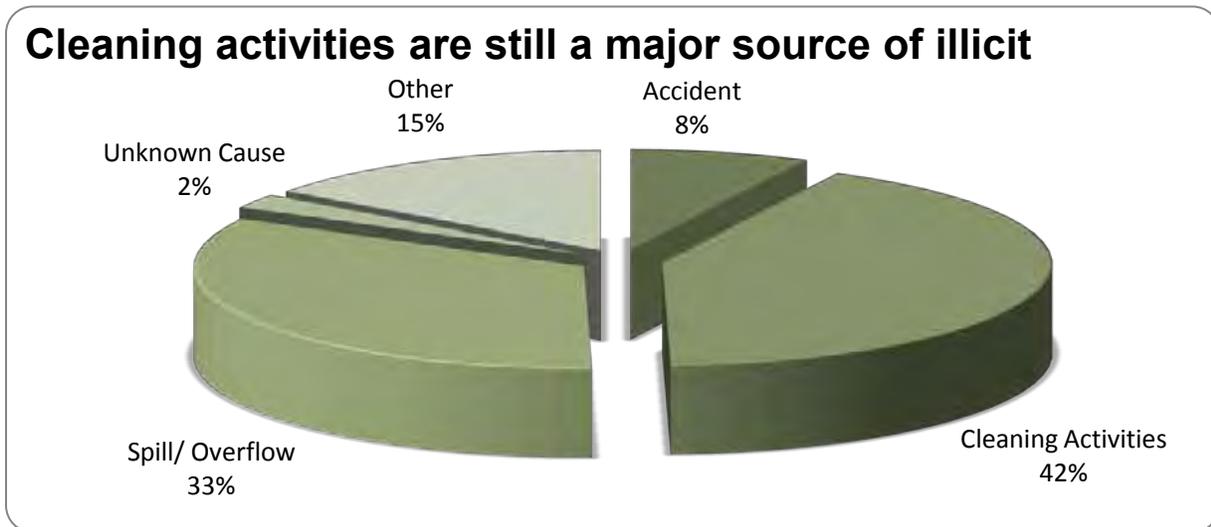

As part of their field investigation of reported illicit discharges/dumping incidents, the Permittees attempt to determine the material's source. This investigation begins at the surface drainage system in the vicinity of suspected illicit discharges. This may include accessible areas in the public right-of-way adjacent to residences and businesses, catch basins, open channels near known points of discharge, and upstream manholes. If the source and responsible party can be determined, Permittees take one, or all, of the following actions when appropriate:

- Voluntary cleanup/termination;
- Initiate enforcement procedures;
- Take steps to prevent similar discharges from reoccurring.

When the source cannot be determined, the appropriate municipal department, or a contractor, will be notified to contain and clean up the material. Because these situations and materials can vary, procedures vary as well. In general, the following are steps that are taken by Permittees to determine sources:

- Verify location of the spill/discharge;
- Containment and cleanup;
- Investigate the cause (look for origin);
- Determine the nature and estimate the amount of illicit discharge/dumped material;
- When appropriate, refer documented non-stormwater discharges/dumping or illegal connections to the proper agency for investigation; and
- If appropriate, notify the RWQCB and/other proper agencies.

Figure 8-7 Sources of Illicit Discharges

8.5 TRAINING – ID3

The Training Control Measure is important for the implementation of the IC/ID Program Element. An effective training program is one of the best pollution prevention BMPs that can be implemented because it prompts behavioral changes that are fundamentally necessary to protect water quality. The Permittees evaluate the efficacy of the training modules they offer by conducting pre- and post-training surveys used to assess a trainee’s command of a topic before and after receiving training on the subject.

8.5.1 Conduct Training

Each Permittee targets staff based on the type of stormwater quality and pollution issues they may encounter. Targeted staff included illicit discharge inspectors, drainage, roadway, landscape and facilities staff, industrial pretreatment inspectors and code enforcement officers. Training is incorporated with existing business inspection, construction site, and public agency activity programs.

Staff is trained in a manner that provides adequate knowledge for effective illicit discharge identification, investigation, reporting and/or clean up. Training was achieved in a variety of ways, including informal “tailgate” meetings, formal classroom training and/or self-guided training methods. During this reporting period, Permittees trained 310 municipal staff on illicit discharge response and non-stormwater discharges. The staff trained by the Permittees is presented in figure 8-8 and training program is outlined in Table 8-4

8.6 EFFECTIVENESS ASSESSMENT – ID4

Effectiveness assessment is a fundamental component required for the development and implementation of a successful stormwater program. In order to determine the effectiveness of the IC/ID Program Element, a comprehensive assessment of the program data is conducted as part of the Annual Report. The results of this assessment are used to identify modifications that need to be made to the Program Element. Each year the effectiveness assessment is reviewed and revised as necessary.

By conducting these assessments and modifying the Program Element as needed, the Permittees ensure the iterative process is used as an effective management tool. Due to the types of data collected for the IC/ID Program, current and future assessments will primarily focus on Outcome Levels 1 through 4.

- Outcome Level 1 (L1) answers the question: Did the Permittees implement the components of the Permit?
- Outcome Level 2 (L2) answers the question: Can the Permittees demonstrate that the control measure/performance standard significantly increased the awareness of its target audience?
- Outcome Level 3 (L3) answers the question: Can the Permittees demonstrate that the control measure/performance standard significantly modified the behavior of a target audience?
- Outcome Level 4 (L4) answers the question: Can the Permittees demonstrate that the control measure/performance standard reduced the pollutant load?

The Permittees have effectively implemented an IC/ID program as described in the following sections. Past Annual Reports have documented the program and are available for public review at the Program's website.³ (L1)

8.6.1 Detection of Illicit Connections and Illicit Discharges Public Outreach Implementation

Public Reporting

Each Permittee has identified staff serving as the contact person(s) for public reporting of IC/ID. The majority of the Permittees maintain a phone hotline to receive IC/ID complaints. (L1) Due to the need for timely response to illicit discharges Permittee web sites direct people to report by telephone to a "live person" instead of through email which, while quickly delivered, may not be read within the short time frame that a discharge is occurring. The Program maintains a website that contains the phone numbers for all the Permittees. (L1)

- For the first few years, as the Stormwater Program evolved and the public became more aware of what was not allowed down storm drains, reports of IC/ID increased; however, for the last five years reports of IC/ID have demonstrated a decreasing trend as shown in Figure 8-1. Since the public is more aware of IC/ID this decrease likely represents a change in behavior and fewer pollutants reaching the storm drains. (L3)

IC/ID Tracking

The Permit requires the mapping of all incidents of illicit connections to their storm drain system since January 2009 by May 7, 2012 at a scale and in a format specified by the Principal Permittee. The Permittees have mapped channels within their permitted area and the storm drain system. These maps

³ <http://www.vcstormwater.org>

were transmitted to the Principal Permittee and were incorporated into the Watershed Protection District's GIS system. (L1)

Screening for Illicit Connections

Screening has been implemented by the Permittees and has proven to be a very labor intensive effort resulting in very few suspect connections turning out to be illicit connections that need to be terminated. Of the 139 possible illicit connections only 26 were identified as actual illicit connections, and as of this report 4 were terminated. As illicit connections are terminated it immediately reduces the discharge of pollutants. (L4)

8.6.1 Illicit Connection and Illicit Discharge Response and Elimination

Legal Authority

Legal authority for most potential pollutant discharges has existed since 1994. More recently Permittees recently adopted a stormwater quality ordinance which more effectively and consistently ensured adequate legal authority across permittees. (L1)

Response to Illicit Discharges and Illicit Connections

Each IC/ID complaint and the actions undertaken in response were documented. (L1) The Permittees responded to all reports of illicit discharge within 24 hours and often within a few hours. (L1) Where possible, the Permittees identified the source, nature, and volume of the discharge. Data shows that the source was identified 95% of the time. The Permittees eliminated all known illicit discharges during this fiscal year. (L1) The Permittees took enforcement action as shown in figure 8-5. (L1)

The Permittees have developed an IC/ID Field Screening Protocol using the guidance from the "Illicit Discharge Detection and Elimination, A Guidance Manual for Program Development and Technical Assessments"⁴ In order to identify high priority areas for inspection, the Permittees have begun to map the storm drain system. (L1) The Permittees investigated all illicit connections identified during inspections or reported by a third party within 21 days. (L1) Where possible, the Permittees determined the source, nature, and volume of the discharge.

8.6.2 Enforcement

Appropriate actions were then taken to approve undocumented connections or pursue removal of illicit connections. Upon confirmation of an illicit connection, the Permittees terminated the connection using formal enforcement within 180 days. (L1) (L4) Some of the Permittees maintained a list containing all connections under investigation for possible illicit connection and their status. (L1) The Permittees eliminated all known illicit connections during this reporting year. (L1)

⁴*Illicit Discharge Detection and Elimination, A Guidance Manual for Program Development and Technical Assessments*. The Center for Watershed Protection, Pitt R., October 2004. Chapter 13, 13.1,13.2, 13.3, 13.4

8.6.3 Training

Conduct Training

During this reporting year, the Permittees trained a total of 310 municipal staff members. Each Permittee targets staff based on the type of stormwater quality and pollution issues they may encounter. Targeted staff included illicit discharge inspectors, drainage, roadway, landscape and facilities staff, industrial pretreatment inspectors, and code enforcement officers. This permitting year 100% of targeted staff members were trained. (L1)

8.6.4 Illicit Discharges and Illicit Connections Program Element Modifications

On an annual basis, the Permittees evaluate the results of the Annual Report, as well as the experience that staff has had in implementing the program, to determine if any additional program modifications are necessary to comply with the Clean Water Act requirement to reduce the discharge of pollutants to the maximum extent practicable.

9 Water Quality Monitoring

9.1 OVERVIEW

As required by Order R4-2010-0108 (issued July 8, 2010), the Ventura Countywide Stormwater Quality Management Program successfully monitored water chemistry, toxicity and biological communities of creeks, rivers, and channels within Ventura County during the 2011/12 monitoring season.

Monitoring locations for water chemistry and toxicity included Mass Emission stations and Major Outfall stations. Mass Emission stations are located in the lower reaches of the three major watersheds in Ventura County (Ventura River, Santa Clara River, and Calleguas Creek). Major Outfall stations, a component of the Stormwater Monitoring Program since 2009, are located in subwatersheds representative of each particular Permittee's contribution to downstream waters.

Water chemistry samples were collected at Mass Emission and Major Outfall stations during three rainfall events, with each site sampled once per event. The rain events occurred on October 5, 2011 (all sites), January 21, 2012 (all sites), and March 17, 2012 (all sites). Samples were collected at Mass Emission and Major Outfall stations during one dry event which was split into three days: April 23, 2012 (MO-MEI, MO-OJA, and MO-MEI), May 21, 2012 (ME-SCR, MO-FIL, MO-OXN, and MO-VEN) and May 23, 2012 (ME-CC, MO-CAM, MO-SIM, MO-THO, and MO-HUE). Note: dry event samples were not collected at MO-SPA or MO-MPK due to lack of flow. Toxicity samples were collected during the first wet event of the season for all fourteen sites. A smaller subset of water chemistry samples was collected at each of the Major Outfall stations (or similar alternate location if no flow was observed) on August 15, 2012, and August 16, 2012, as part of the dry -season, dry-weather monitoring prescribed in the NPDES permit.

Through rigorous adherence to the Stormwater Monitoring Program's sampling protocols and through selection of a high-quality analytical laboratory, the Stormwater Monitoring Program was able to achieve a 91.8% success rate in meeting program data quality objectives.

This year the Ventura Countywide Stormwater Quality Management Program re-evaluated and modified its application of the California Toxics Rule (CTR) Numeric Criteria for Priority Toxic Pollutants to determine water quality exceedances in receiving waters. The driver for this change was the inconsistent application of acute and chronic criteria in the past. The new approach provides more consistent protection of beneficial uses and is more consistent with how other stormwater agencies in southern California determine. The details and benefits of the new approach, and the implications for historical exceedances are discussed in this report.

Aluminum, E. coli and fecal coliforms were commonly found at elevated levels at most sites during wet-weather events, but with the exception of E. coli, rarely during dry-weather events. Other constituents that were found at elevated levels during the 2011/12 monitoring season include chloride and total dissolved solids (predominantly during the dry-weather event); dissolved oxygen; dissolved copper; and pH (dry weather). Constituents that were seen at elevated levels at Major Outfalls only once during the season include total chromium, bis(2-ethylhexyl)phthalate, benzo(a)pyrene, and pentachlorophenol. Constituents that were seen at elevated levels at Mass Emission stations only once during the season include the metals (total) barium, cadmium, chromium, and nickel. The Program is using this information to identify pollutants of concern and direct efforts to reduce their discharge from the storm drain system.

Bioassessment sampling was performed at fifteen random [probabilistic (P)] and three targeted [trend (T)] sites throughout Ventura County, divided among each of the three major watersheds (six P and one T in the Ventura

River Watershed, six P and one T in the Calleguas Creek Watershed, and three P and one T in the Santa Clara River Watershed). Sampling was conducted over eight days between June 4, 2012 and July 19, 2012.

The Ventura Countywide Stormwater Quality Management Program started a comprehensive data analysis effort, aiming to identify historical trends in water quality, priority pollutants and their sources to receiving waters. As part of this year's report, the trend analysis results are presented.

9.2 INTRODUCTION

This report summarizes the effort undertaken by the Ventura Countywide Stormwater Quality Management Program (Program) and the Stormwater Monitoring Program during the 2011/12 monitoring season. Pursuant to NPDES Permit No. CAS0040002, the Program must submit a Stormwater Monitoring Report annually by December 15th, and include the following:

- Results of the Stormwater Monitoring Program
- General interpretation of the results
- Tabular and graphical summaries of the monitoring data obtained during the previous year

Analysis of samples collected at various stations throughout the watershed gives an overall representation of the quality of stormwater discharges. The monitoring also aids in the identification of pollutant sources, as well as the assessment of Program effectiveness. Feedback provided by the monitoring program allows for changes to be made in the implementation of other Program aspects in order to resolve any problems and reduce pollutants that may exist. This adaptive management strategy should eventually show improved water quality through the stormwater monitoring program. The Stormwater Monitoring Program includes the following components.

9.2.1 Mass Emission Monitoring

Mass Emission stations are located in the lower reaches of the three major watersheds in Ventura County (Ventura River, Santa Clara River, and Calleguas Creek). As such, the Mass Emission drainage areas are much larger than the drainage areas associated with Major Outfall stations (described in Section 9.2.2), and include large contributions from other sources of discharge, such as wastewater treatment plants, agricultural runoff, non-point sources, and groundwater discharges.

The purpose of mass emission monitoring is to identify pollutant loads to the ocean and identify long-term trends in pollutant concentrations. This type of monitoring, in conjunction with the Major Outfall monitoring, is also useful in helping to determine if the Municipal Separate Storm Sewer System (MS4) is contributing to exceedances of water quality objectives by comparing results to applicable water quality objectives in the Los Angeles Region Water Quality Control Plan (Basin Plan) and the California Toxics Rule (CTR), as described in Section 9.5.1.

During the 2011/2012 monitoring season, water quality samples from three wet-weather events and one dry-weather event were collected for water chemistry analysis at each Mass Emission station, as required by the NPDES permit. Also, aquatic toxicity samples were collected at each Mass Emission station during Event 1 (October 5, 2011) and tested with the species that was determined to be the most sensitive to contaminants for each station, based on the results from the 2009/10 monitoring year. In addition, trend analysis was performed for all constituents using historical data from Mass Emission stations, in order to identify potential improvements or deterioration in chemical water quality since 2001.

9.2.2 Major Outfall Monitoring

The Permit requires sampling at one representative station (major outfall) for each Permittee's municipal separate storm sewer system (MS4). Many of the monitoring requirements for Major Outfall stations are similar to those for the Mass Emission stations, as are the reasons for undertaking this monitoring. Four of the stations were monitored beginning with the 2009/10 monitoring season and seven of the stations were new to the 2010/11 monitoring season. Station selection for these new sampling locations is described in Section 9.3.2.

During the 2011/12 monitoring season, water quality samples from three wet-weather events and one dry-weather event were collected for water chemistry analysis at each of the eleven Major Outfall stations⁵, as required by the NPDES permit. Aquatic toxicity samples were collected at each of the Major Outfall stations during Event 1 (October 5, 2011) and tested with the species that was determined to be the most sensitive to contaminants for that station, based on the results from the 2009/10 or 2010/11 monitoring year, as applicable.

Using the data from the Major Outfall monitoring in conjunction with the Mass Emission monitoring, the Stormwater Monitoring Program will help the Program determine if an MS4 is potentially contributing to exceedances of water quality objectives by comparing results to applicable water quality objectives in the Basin Plan and the CTR. And, over the course of many years, the data will be able to describe trends in waters from the Major Outfall stations over time. This information will be useful in evaluating the effectiveness of the Program implementation and provide Permittees with real data on which to base future management decisions.

9.2.3 Dry-Season, Dry-Weather Analytical Monitoring

The Permit requires the analysis of pollutant discharges from representative MS4 outfalls in each municipality and in the unincorporated County area during dry-weather between May 1 and Sept 30. The Stormwater Monitoring Program met this requirement by sampling once during the summer at or near Major Outfall stations, or at another representative site if flow was insufficient at the Major Outfall station.

9.2.4 Bioassessment Monitoring

Prior to the adoption of the new Orders (No. 09-0057 in 2009 and its replacement, R4-2010-0108 in 2010), the Stormwater Monitoring Program performed bioassessment monitoring in the Ventura River watershed at fixed locations. That sampling effort was terminated in favor of a new program working to standardize bioassessment monitoring throughout Southern California undertaken by the Stormwater Monitoring Coalition of Southern California (SMC) and led by the Southern California Coastal Water Research Project (SCCWRP). The Stormwater Monitoring Program was instructed to participate in this new program by performing sampling at 15 random sites and three targeted sites throughout the County annually, for the duration of the five year study. The sampling for this report year was performed in early summer of 2012.

⁵ With the exception of MO-SPA and MO-MPK which were not sampled during the dry weather event due to a lack of consistent flow.

9.3 MONITORING STATION LOCATIONS AND DESCRIPTIONS

9.3.1 Mass Emission Stations

Mass Emission stations are located in the three major Ventura County watersheds: Ventura River (ME-VR2), Santa Clara River (ME-SCR), and Calleguas Creek (ME-CC). In locating these stations, every effort was made to position the station as low as possible in the watershed to capture as much of the runoff as possible, while still remaining above tidal influence. See Figure 9-1 for the location of Mass Emission stations.

The ME-VR2 station is located at the Ojai Valley Sanitary District's wastewater treatment plant (WWTP) near Canada Larga Road and captures runoff from the city of Ojai, several unincorporated communities (e.g., Meiners Oaks, Casitas Springs), and a large portion of undeveloped landscape, the latter of which comprises the bulk of the watershed. Monitoring at the ME-VR2 station was initiated during the 2004/05 monitoring season after landslide activity at the original Ventura River Mass Emission station, ME-VR, precluded further sampling at that location.

The ME-CC station is located along University Drive near California State University at Channel Islands and captures runoff from the cities of Camarillo, Thousand Oaks, Moorpark and Simi Valley. This watershed has the largest urban influence (roughly 30% urbanized), but also includes significant contributions from agricultural runoff found predominantly in the lower two-thirds of the watershed. Monitoring at the ME-CC station was initiated during the 2000/01 monitoring season.

The ME-SCR station is located at the United Water Conservation District's (UWCD) Freeman Diversion Dam east of Saticoy and captures runoff from the cities of Santa Paula and Fillmore, communities upstream in Los Angeles County, agricultural fields, and a large amount of undeveloped landscape. Monitoring at the ME-SCR station was initiated during the 2001/02 monitoring season. Unlike at the other two Mass Emission stations, accurate measurement of flow at this location is not possible due to the configuration and operation of the diversion structure. In dry conditions, the river is usually diverted to groundwater infiltration ponds. In wet-weather conditions, the Santa Clara River can also flow past the diversion dam through two other routes. One route is through the river diversion gate structure where the majority of wet-weather flow passes. The other route is over the diversion dam, a situation which occurs only during high flows generated by large storm events. Wet-weather flow can only be measured at the diversion dam because there is no flow meter installed at the river diversion gate. There are technical challenges involved with measuring flow at the river diversion gate since floating debris and sediment can interfere with flow measurement and the large fluctuation in water level due to gate operation makes non-contact stage measurement difficult.

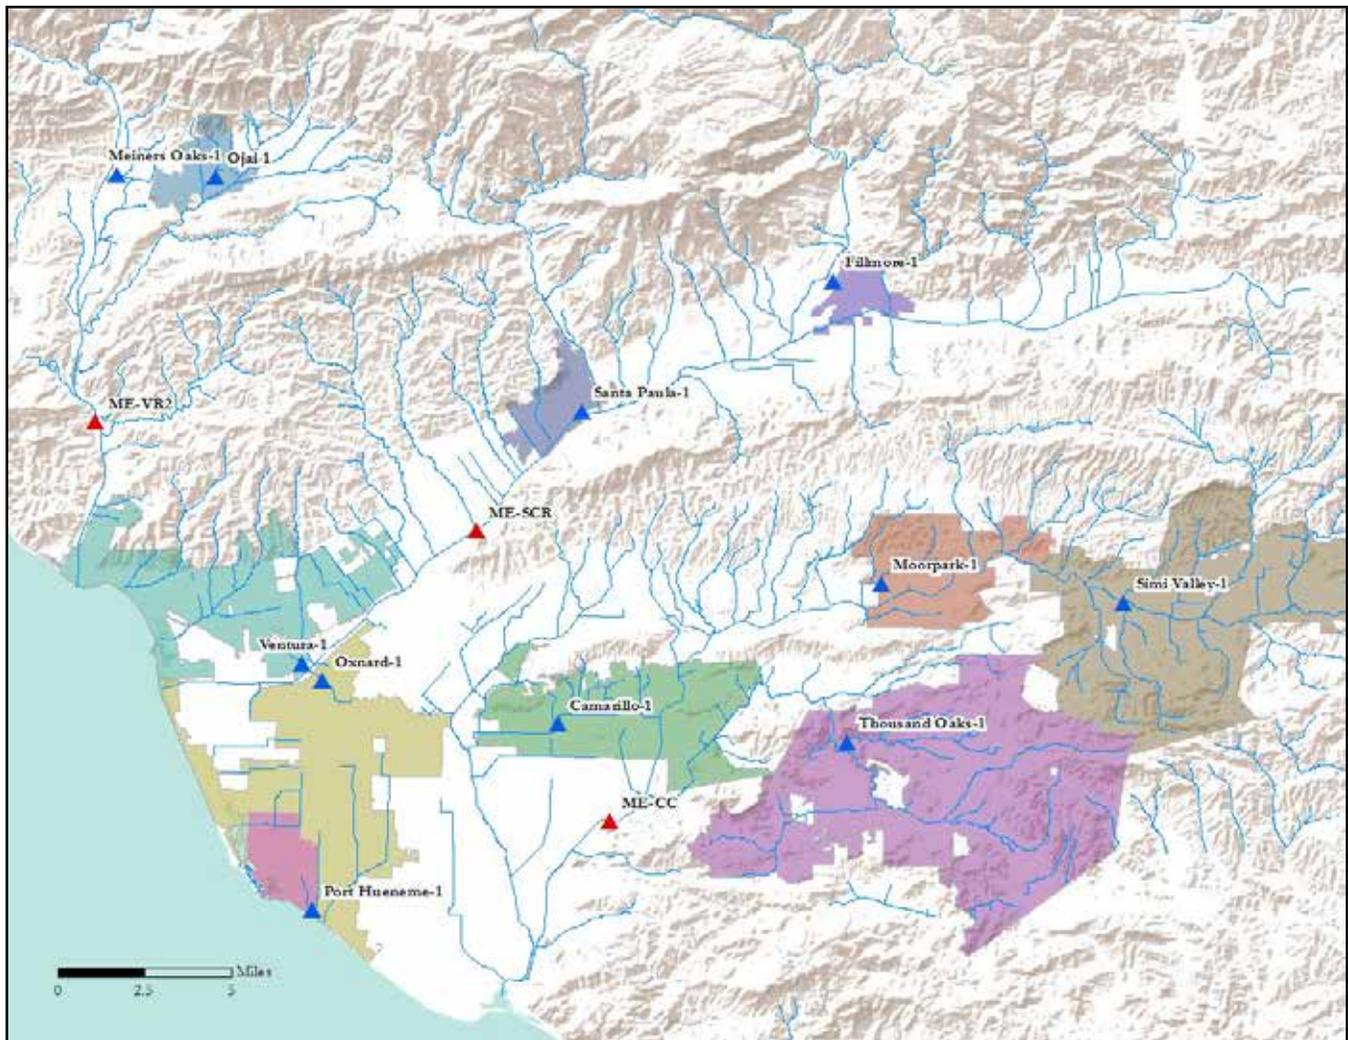

9.3.2 Major Outfall Stations

Of the eleven Major Outfall stations, four were added to the Stormwater Monitoring Program in 2009 and seven were added in 2010. As directed by the NPDES permit, these stations represent the runoff from each city/unincorporated county (Permittee) in which they are located. Municipalities selected for inclusion in the 2009/10 Stormwater Monitoring Program include Camarillo (MO-CAM), Ojai (MO-OJA), unincorporated Meiners Oaks (MO-MEI) and Ventura (MO-VEN).⁶ The stations in the seven remaining municipalities brought

⁶ Site names shown on the map reflect the names given to each site in the NPDES permit; site names throughout this report are shortened to those shown on chains-of-custody (COCs) for brevity. Under this naming convention, MO-CAM is synonymous with Camarillo-1, MO-FIL with Fillmore-1, MO-HUE with Port Hueneme-1, MO-OJA with Ojai-1, MO-OXN with Oxnard-1, MO-MEI with Meiners Oaks-1 (VCUunincorporated-1), MO-MPK with Moorpark-1, MO-SPA with Santa Paula-1, MO-SIM with Simi Valley-1, MO-THO with Thousand Oaks-1, and MO-VEN with Ventura-1.

online for the 2010/11 Stormwater Monitoring Program include Fillmore (MO-FIL), Moorpark (MO-MPK), Oxnard (MO-OXN), Port Hueneme (MO-HUE), Santa Paula (MO-SPA), Simi Valley (MO-SIM), and Thousand Oaks (MO-THO). Details of the land use of each city and the representative watershed can be found in Appendix A in Attachment E.

Figure 9-1 Mass Emission and Major Outfall Sampling Locations

The MO-CAM station is located on Camarillo Hills Drain (a tributary of Revolon Slough) just north of Daily Drive in Camarillo. The predominant land use in the watershed is residential. Less than 8% of the watershed is commercial and less than 1% is agricultural.

The MO-OJA station is located on Fox Canyon Barranca (a tributary of San Antonio Creek) near the Ojai Valley Athletic Club in Ojai. Almost half of the watershed is classified as vacant, with residential land use comprising about 40%. About 3% of the watershed is commercial and about 5% is agricultural.

The MO-MEI station is located on Happy Valley Drain (a tributary of the Ventura River) near Rice Road in Meiners Oaks. Almost half of the watershed is classified as residential. Another quarter of the watershed is classified as vacant. About 3% of the watershed is commercial and about 15% is agricultural.

The MO-VEN station is located on Moon Ditch (a tributary to the Santa Clara River) near the US101-Johnson Drive interchange in Ventura. Over half of the watershed is residential and a quarter is commercial. Industrial land uses account for almost 7% of the watershed, while agriculture comprises less than 1% of the watershed.

The MO-FIL station is located on the North Fillmore Drain (a tributary of Sespe Creek) near Shiells Park in Fillmore. Almost half the watershed is residential and just over a third is classified as vacant. Agriculture land uses account for almost 7% of the watershed, while commercial comprises less than 1% of the watershed.

The MO-MPK station is located on the Gabbert Canyon Drain (a tributary to Arroyo Las Posas) near the intersection of Los Angeles Avenue and Mira Sol Drive. Over half the watershed is classified as vacant, less than 10% of the land is residential, and almost 13% of the watershed is used for agriculture.

The MO-OXN station is located on El Rio Drain (a tributary to the Santa Clara River) near the corner of Buckaroo Avenue and Winchester Drive. Most of the watershed is classified as residential, however almost 20% is commercial and less than 2% is agricultural.

The MO-HUE station is located on Hueneme Drain (a tributary of the J Street Drain at the Pacific Ocean) southeast of Bubbling Springs Park. The land use is predominantly residential, with commercial and vacant land uses accounting for only 3% each.

The MO-SPA station is located on the 11th Street Drain where it enters the Santa Clara River, east of the Santa Paula airport. About half of the watershed is classified as residential, less than 15% as commercial, and schools and transportation account for about 10% each.

The MO-SIM station is located on Bus Canyon Drain (a tributary of the Arroyo Simi) near the intersection of 5th Street and Los Angeles Avenue. Over half (57%) of the watershed is classified as vacant and about one third is residential. All other land uses account for less than 1% of the watershed each.

The MO-THO station is located on the North Fork Arroyo Conejo (a tributary to Conejo Creek) in the Hill Canyon WWTP. The main land uses in the watershed are residential (56%) and vacant land (31%).

Figure 9-1 shows the location of the eleven Major Outfall and three Mass Emission stations.

9.4 METHODS

The NPDES permit requires flow-paced sampling at monitoring stations where technically feasible. The reason for this type of sampling is two-fold. First, by collecting sub-samples (aliquots) based on flow, a more accurate representation of the Event Mean Concentration (EMC) of each constituent in the runoff can be achieved. Second, by multiplying the EMC by the total flow during sample collection, a mass of each constituent discharged during each sampling event can be determined. Ideally, sampling events represent the entire hydrograph, however difficulties inherent in predicting precipitation quantity, intensity, and resulting runoff may result in partial representation of the complete storm event. Therefore, EMC are only representative of the sampling event duration and not the entire storm and mass emission quantities are calculated accordingly. These benefits are discussed further below.

Flow-paced sampling is not technically feasible at three sites, ME-SCR, MO-FIL, and MO-HUE. Since its installation in 2001, the monitoring station at ME-SCR has been monitored on a time-paced basis, as allowed by the RWQCB. This site is located at the UWCD's Freeman Diversion Dam, where irregular operation of the gates associated with the diversion dam makes it impossible to calculate flow. During most of the year, water is sent through a canal in which it is easy to calculate flow. However, during rainfall events and periodically throughout the year, the UWCD will close the gates to the diversion canal, allowing water to go through a high-velocity bypass or spill over the dam itself. Computing flow over the latter is difficult, given the breadth of the dam, which spans the entire river bottom. Computing flow through the bypass is impossible due to the wide ranges in water surface elevation and velocity. The MO-FIL station is located at an outfall into Sespe Creek and is subject to backwater due to plant growth and sediment deposition, which makes accurate flow determination impossible. The MO-HUE station is located in a canal which is drained via pumps that are triggered based on water surface elevation. The pumps are operated intermittently which makes flow-paced sampling inappropriate.

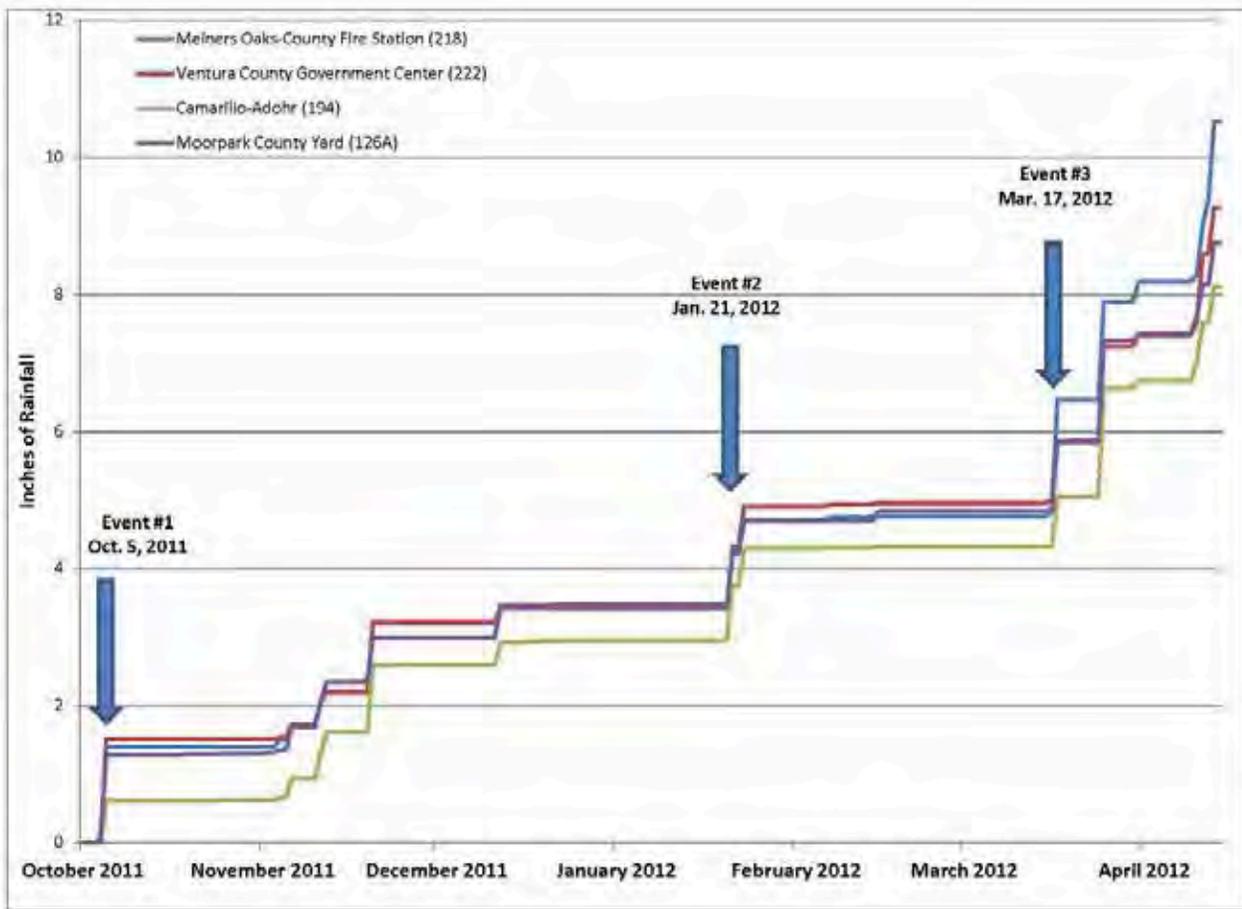

9.4.1 Precipitation

Precipitation amounts, both historical and predicted, are integral to performing flow-weighted sampling. Historical precipitation data is necessary to determine the relationship between rainfall and runoff. In the major watersheds with long-term Mass Emission stations, the rainfall-to-runoff (RTR) ratio is based on over 65 years of data and takes into account antecedent soil moisture conditions. These RTR tables have been used and refined by the Stormwater Monitoring Program for over 10 years.

At the time the Major Outfall stations were installed, the Stormwater Monitoring Program had access to real time precipitation data from the VCWPD's Hydrology section [part of the Automated Local Evaluation in Real Time (ALERT) network]; however it was not in a form that was usable by the Program. Changes to the processing of the ALERT data allowed the Program to capitalize on the already installed and maintained ALERT rainfall gauges. Most of the monitoring stations were able to use data from nearby ALERT gauges. Those monitoring stations that do not have nearby ALERT gauges (ME-SCR, ME-VR2, MO-CAM, MO-MEI, MO-VEN, and MO-HUE) have tipping bucket rainfall gauges (0.01" per tip) installed instead.

While the rainfall gauges purchased and maintained by the Stormwater Monitoring Program are of high quality, the data generated by these gauges are subjected to less stringent quality control measures than the "official" gauges maintained by the Hydrology section. Therefore, the Stormwater Monitoring Program has opted to show cumulative totals from representative ALERT gauges when indicating dates that actual sampling events occurred, as shown in Figure 9-2 Precipitation at Selected Sites. Gauge 218 is located in the Ojai Valley near the MO-MEI station. Gauge 222 is located at the County Government Center near the MO-VEN station. Gauge 194 is located at the base of the Conejo Grade, somewhat equidistant from the ME-CC and MO-CAM stations. Gauge 126A is located at the Moorpark County Yard near the MO-MPK station. Rainfall data gathered at specific monitoring stations can be found in Appendix B in Attachment E.

Figure 9-2 Precipitation at Selected Sites

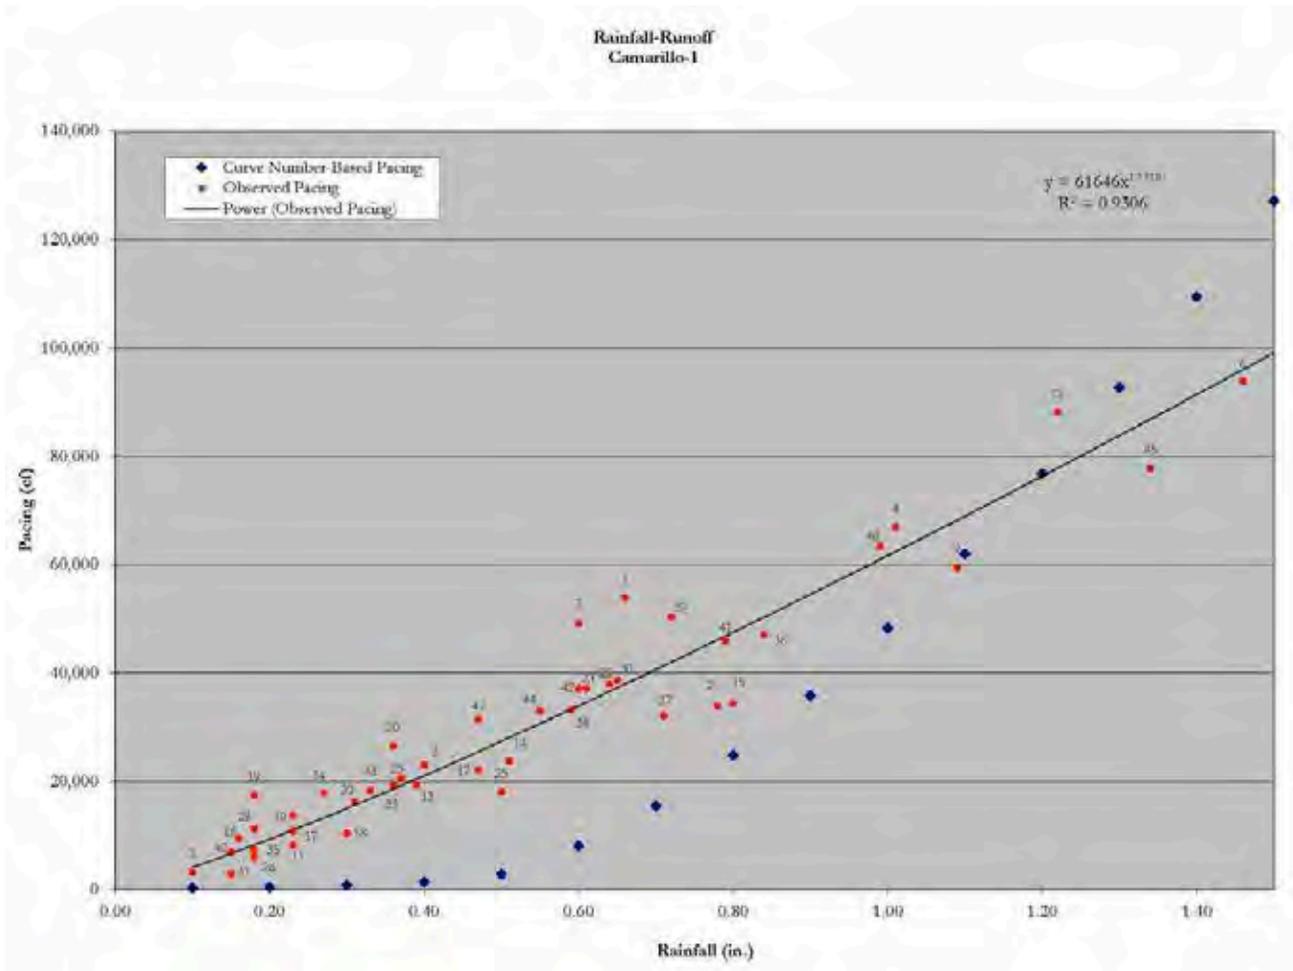

9.4.2 Rainfall-to-Runoff Ratios

Prior to starting monitoring under the new permit (before monitoring season 2009/10), the Stormwater Monitoring Program enlisted the VCWPD's Hydrology section to assist in modeling the expected rainfall-to-runoff (RTR) ratio for each new Major Outfall station. The Hydrology section used the NRCS Curve Number approach that is commonly used in hydrologic modeling. This model takes into account land use and soil types within each watershed, but relies on using a wetter soil moisture condition than actually exists for all but the largest of rainfall events. Despite these known limitations, these RTR ratios represented a good beginning point for flow-weighted sampler pacing. A further description of the methods and limitations of this approach, as described by the Hydrology section, can be found in Appendix C in Attachment E.

Over the course of the 2009/10, 2010/11, and 2011/12 monitoring years, the Stormwater Monitoring Program refined these model results by comparing the runoff generated at each site with the corresponding rainfall, where runoff was sufficient to be detected by the equipment and rainfall was greater than 0.1 inch. Figure 9-3 shows an example of these two pieces of information, as a function of the proper pacing of the automated sampler (see Section 9.4.3 for a further description of sampler pacing).

Figure 9-3 shows all rainfall events together, regardless of antecedent soil moisture conditions. However, as more data becomes available, the RTR ratios will be divided into dry, moderate and wet antecedent soil moisture conditions as has been done for the Mass Emission stations. This will allow the Stormwater Monitoring Program to more accurately pace automated samplers based on the predicted size of each storm.

Figure 9-3. Example of Rainfall-to-Runoff Modeling Versus Actual Rainfall Events

9.4.3 Flow-Paced Sampling

To compute flow, ISCO flow meters were installed at all locations (except at the aforementioned ME-SCR, and at MO-HUE, where the pump station prevents flow from being able to be measured accurately). ISCO 4230 bubblers were installed at all other stations except MO-FIL and MO-SPA, which received ISCO 4250 area-velocity meters instead. By measuring pressure head and relating it to a rating table, ISCO 4230s are capable of calculating instantaneous discharge. Measurement accuracy of the 4230 is not affected by wind, steam, foam, turbulence, suspended solids, or rapidly changing head heights. These types of flow meters are extremely low maintenance and highly reliable and were, therefore, chosen over other contact (ISCO 4250 area-velocity) and non-contact (ISCO 4210 ultrasonic) types of flow measuring devices when possible. ISCO 4250 area-velocity meters use Doppler technology to directly measure average velocity in the flow stream, while the integral pressure

transducer measures liquid depth to determine flow area. The 4250 then calculates flow rate by multiplying the area of the flow stream by its average velocity. The 4250 is best for applications where weirs or flumes are not practical, or where submerged, full pipe, surcharged, and reverse flow conditions may occur, such as at the MO-FIL and MO-SPA monitoring sites.

Flow-paced sampling involves collecting sub-samples (aliquots) on a volumetric flow interval basis, with a set aliquot volume collected at passage of each equal, pre-set flow volume, and then compositing these aliquots into one sample for analysis. In its simplest terms, flow-paced sampling can be achieved by estimating the total flow that will pass a sampling location (which, itself, is dependent on predicted rainfall amounts and intensities) and dividing that by the number of aliquots to be taken. Using Figure 9-3 above as an example, an approximate 1.0” rainfall event would generate about 2.3 million cubic feet of runoff, which when divided by 35 (the number of aliquots the Stormwater Monitoring Program attempts to take per event at each site) provides the proper pacing of around 67,000 cubic feet per aliquot (see data point #4). As mentioned above, this pacing volume is highly dependent on other variables such as intensity and antecedent soil moisture conditions.

Although composite samplers are automated, Stormwater Monitoring Program staff actively monitored storm and flow conditions during each event in order to adaptively adjust the sampler to capture the best representation of storm flow. This was made possible by the new telemetry capabilities of the Stormwater Monitoring Program. Previously, Stormwater Monitoring Program staff members were required to visit each site as the timing and amounts of predicted rainfall changed. Each site is now equipped with a cellular modem that makes communication and changes to sampler pacing and timing possible. Furthermore, the data from each of these sites is pushed via a static IP address to a centrally located SQL server and is accessible in near real-time format. Due to this set-up, site visits were only necessary to set up the site initially, take grab samples, collect composite sample bottles, and correct physical problems with the site. A schematic of this set-up is shown in Figure 9-4. An example of the data available to Stormwater Monitoring Program staff in the Storm Control Center is shown in Figure 9-5.

Figure 9-4. Schematic of Remote Data Delivery and Access

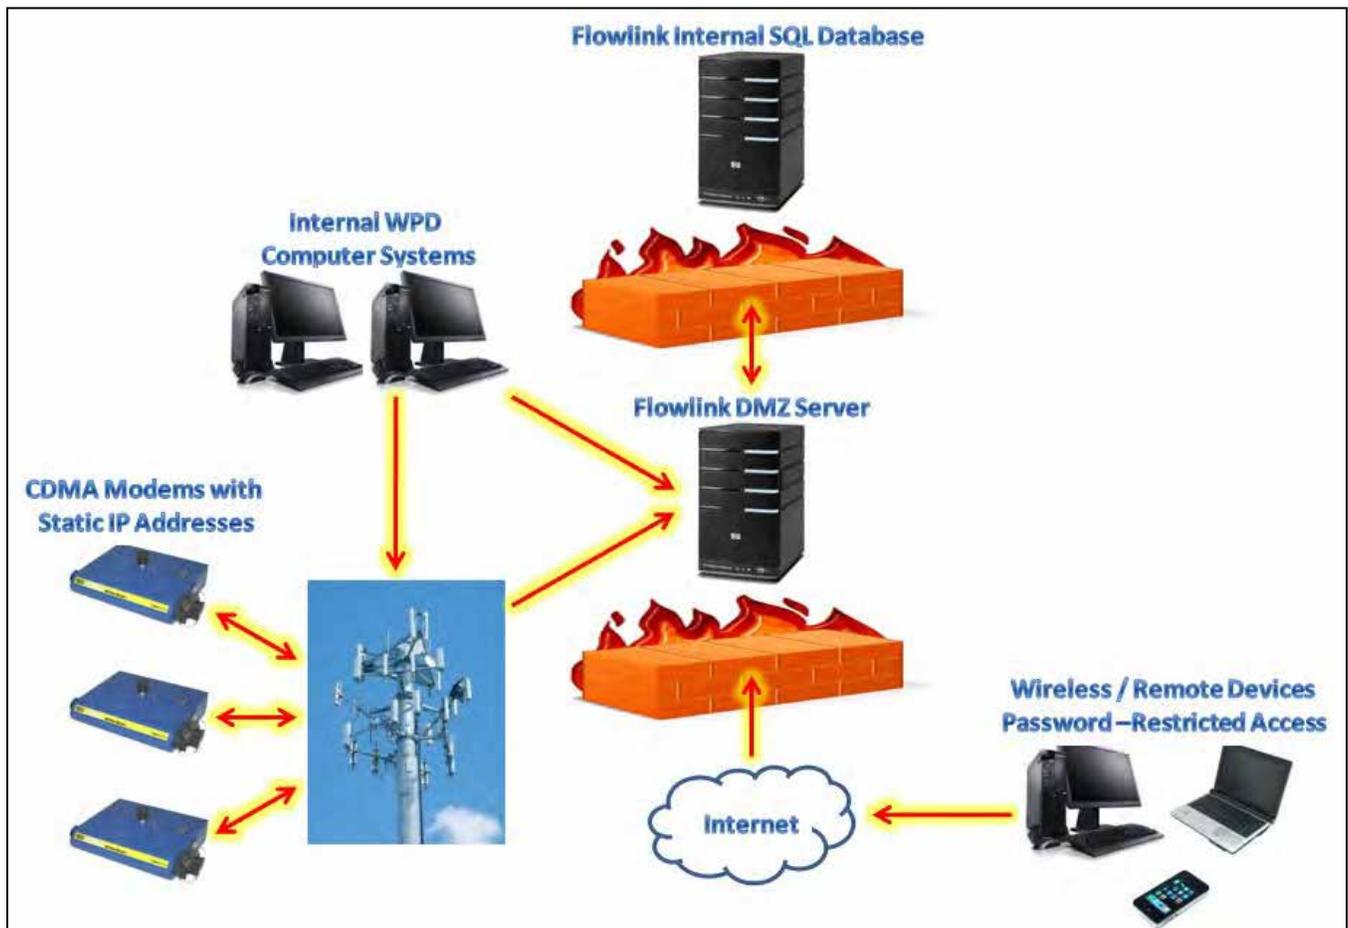

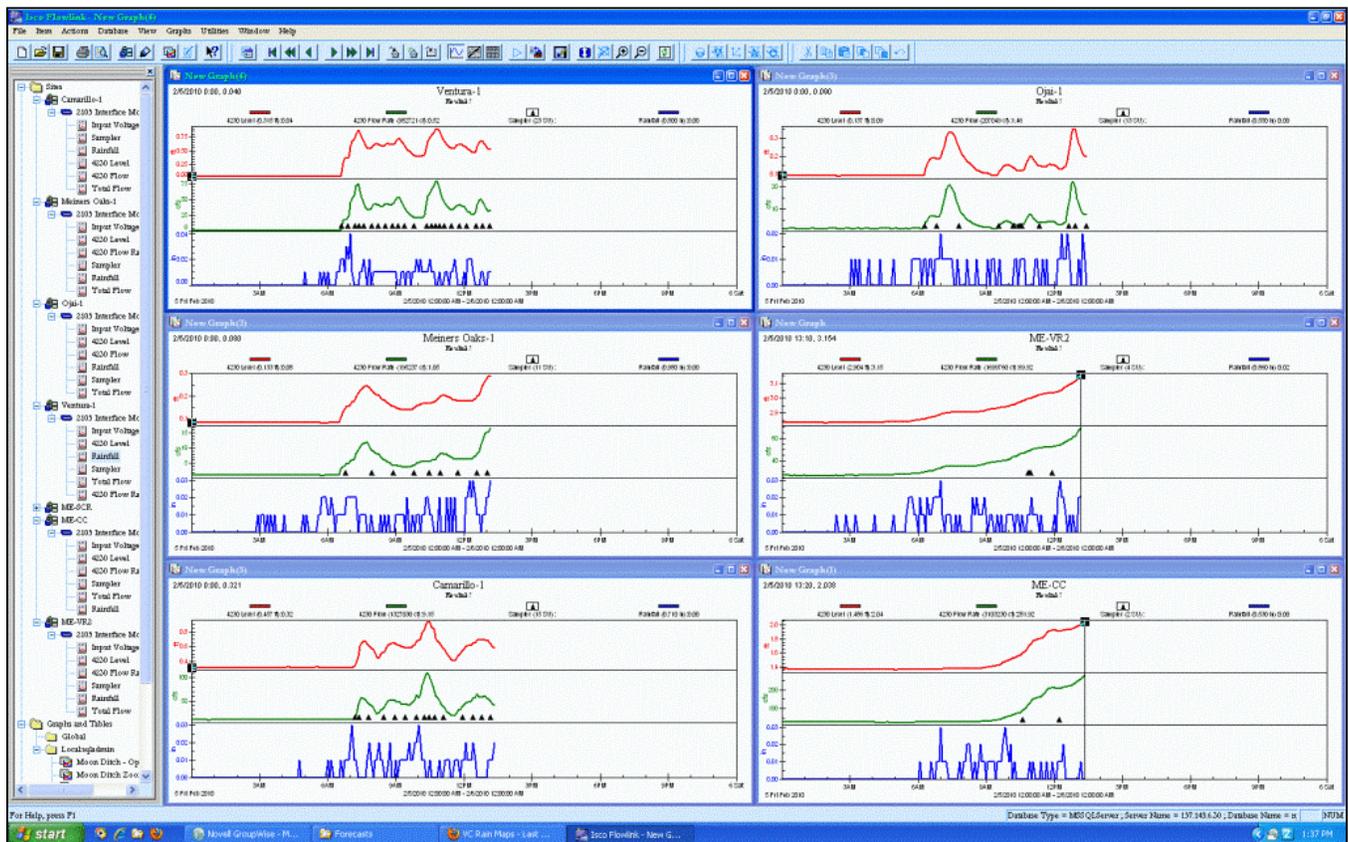

Figure 9-5. Real-Time Data Available in Storm Control Center

9.4.4 Sample Collection

As detailed in the NPDES permit, the Stormwater Monitoring Program was to sample three wet-weather events, described as a greater than 20% increase in base flow preceded by at least 7 days of dry weather (<0.10” each day), and one dry-weather event during each Permit year. Emphasis was placed on capturing the first event of the year, as well as the first part of each storm, both of which can be described as the first flush. The Stormwater Monitoring Program was able to successfully sample the necessary quantity and type of events as dictated by the NPDES permit, with the exception of ME-SCR in Event 1 (reduced sample volume due to UWCD turnout) and MO-SPA and MO-MPK in Event 4 (which had insufficient flow for sample collection). See Table 9-1 for site flow and event durations.

In Table 9-1, Start Date/Time and End Date/Time describe the length of time the automated sampler was actually taking samples. The true time of the rainfall and related runoff event was always longer; since the samplers were programmed to begin taking samples after flow had risen to greater than 20% of base flow, which took 0.10” to 0.25” of rainfall, depending on the antecedent conditions and sampling location.⁷ Furthermore, flow often

⁷ This range represents the amount of rainfall needed to generate measurable flow at the monitoring station. Smaller amounts of rainfall generated positive flow in watersheds with proportionally more impervious area. All automated sampling programs were designed to begin

continued after the automated sampler had completed its sampling program, because of the Stormwater Monitoring Program’s goal to ensure that enough aliquots were taken to perform the required analyses. Because of this goal, the Stormwater Monitoring Program erred on the conservative side, pacing the samplers a bit quicker than the RTR tables dictated. As the RTR tables are refined, this error will become smaller, but will never completely disappear due to the inherent error in rainfall predictive abilities by both commercial and public weather forecasters. The relative timing of the onset of rainfall, commencement of the sampling program and duration of the flow for each site can be found in the event hydrographs located in Appendix B in Attachment E and is described further in the event descriptions, below.

The sampling methods and sample handling procedures used during the 2011/12 monitoring year are described in *Ventura Countywide Stormwater Monitoring Program: Water Quality Monitoring Standard Operating Procedures, 2009-2014*.

* All times PST

^a Event Date describes the date on which composite sampling began for a particular monitoring event.

^b Start Date/Time and End Date/Time describe the duration samples were actually taken.

^c Time-paced as flows cannot be accurately measured at these sites. ME-SCR: During wet weather the Santa Clara River flows through the river diversion gate and over the diversion dam. Currently, there is no flow meter installed at the river diversion gate where a majority of the wet weather flow passes. MO-FIL: Site experiences ponding and backwater effects due to natural bottom channel. MO-HUE: Flow is dependent on the release of water at the Hueneme pump station.

^d Flow is estimated as dry weather flows are below the threshold levels for measurement.

^e Insufficient flow over 24 hours available for sample collection.

At all monitoring stations, both composite and grab samples were collected. Composite samples were collected in glass containers and then delivered to the lab, where they were split by agitating the bottle, pouring off the necessary volume into a sample bottle, and repeating as necessary. When the splitting of a composite sample was performed, the composite sample was continually agitated to provide as much "non-invasive" mixing as possible. Sample splitting allowed homogeneous aliquots of a single, large water sample to be divided into several smaller sub-samples for different analyses. The volume of sample collected depended upon the volume required by the lab to perform requested water quality and QA/QC analyses.

Grab samples were taken as close to mid-stream, mid-depth as possible by immersing the sample bottle directly in the water (see Figure 9-6). In some situations, site conditions precluded such sampling and alternative sampling techniques were used. At the larger, deeper Mass Emission stations, grab samples were often gathered near the bank, but still in positive flow, often with the help of a long, extended swing sampler (see Figure 9-7). This technique was also employed at some of the Major Outfall stations where getting into the channel would have compromised personnel safety.

Figure 9-6. Grab Sampling at Mid-Stream, Mid-Depth

For constituents analyzed from samples required to be collected as “grabs,” samples were ideally taken at the peak runoff flow to provide the best estimate for an event mean concentration (EMC). In practice, it was difficult to both predict the peak flow for each site and to allocate manpower such that all sites were grab-sampled at the storm event peak flow. It should be noted that peak flow times varied for each monitoring station due to the size and inherent characteristics of the watershed in which the site was located, as well as varying durations and intensities of rainfall. All grab and composite wet weather samples collected during the 2011/12 monitoring season are considered best available estimates of storm EMCs.

The chemical analysis of some constituents is not possible in a laboratory setting and must be performed in the field. These constituents were analyzed using pre-calibrated field meters at the time when grab samples were collected. All field meters were calibrated according to manufacturers’ directions, using vendor-supplied calibration solutions where applicable

In an effort to maintain quality control for the sampling program, the sampling crew, in cooperation with the analytical laboratories, has minimized the number of laboratories and sample bottles used for analysis. This has minimized bottle breakage, increased efficiency, and reduced the chances for contamination of the samples. Also, a dedicated monitoring team was used to provide consistent sample collection and handling.

As a means of documenting all preparatory, operational, observational, and concluding activities of a monitoring event, the Stormwater Monitoring Program produced an event summary for each monitoring event. These event summaries include, but are not limited to, information related to event duration, predicted and actual precipitation, weather conditions, the programming of sampling equipment, equipment malfunctions, sample collection and handling, and sample tracking with respect to delivery to analytical laboratories. All event summaries associated with the 2011/12 monitoring season are presented in Appendix D in Attachment E.

Figure 9-7. Grab Sampling Using Extended-Reach Swing Sampler

The Stormwater Monitoring Program also documented the actual samples it collected at each monitoring site – and the date and time of collection – during the course of an event by completing a chain of custody (COC) form for each sampling event. The COC form not only documented sample collection, but also notified an analytical laboratory that a particular sample should be analyzed for a certain constituent or group of constituents, oftentimes specifying the analytical method to be employed. Finally, the COC form acted as an evidentiary document noting how many samples were relinquished – and at what date and time – to a particular laboratory by the Stormwater Monitoring Program. All chain of custody forms associated with

the 2011/12 monitoring season are presented in Appendix E in Attachment E.

The QA/QC sampling schedule was designed to be flexible in response to changing conditions, with the analytical chemistry laboratory being instructed to utilize VCWPD samples for MS/MSD and laboratory duplicate analyses when sample volume was sufficient, rather than for specific sites for each event. This flexibility is of benefit for several reasons. First, as is often the case, rainfall duration and intensity were difficult to predict, especially in the early part of the season. Second, extremely dry antecedent conditions made forecasting flow conditions at the various monitoring locations complicated. Finally, site-specific complications can affect sample volume. An example of this is the operation of the diversion canal at ME-SCR by UWCD, which can leave the primary intake line of the sampler out of the water, thereby causing insufficient sample volume as the sampler pulls air instead of river water. While the Stormwater Monitoring Program has installed multiple intake lines to deal with this situation, the time at which UWCD opens the gates to the diversion structure must be known and since UWCD's operation of this structure depends on turbidity in the river, it is extremely difficult to predict when the primary intake line ceases to become useful and the sampler needs to be switched over to the secondary intake line. The flexibility in QA/QC sampling station selection allows the laboratory more options for using VCWPD samples for QA/QC tests than would otherwise be possible, due to the ability to select sites with surplus volume.

Event 1 (Wet)

The first rainfall event of the year began early in the morning on October 5, 2011, with the bulk of the rain falling before noon on the same day. Rainfall was estimated at 0.50" to 1.0" at the monitoring sites. The rainfall lasted approximately 10 hours and by the time the storm had moved through the area, approximately 0.6" of rain had fallen at the coast and up to 1.7" had fallen inland. Most sites received more than an inch of rain.

UWCD temporarily stopped diverting the water on 10/5/2011 due to high turbidity. This resulted in a reduced sample volume of 5 liters to be collected at ME-SCR. The laboratory initiated the priority list for analyses.

Event 2 (Wet)

The second monitoring event of the season began around midnight on the morning of January 21, 2012. Rainfall estimates of 0.25" to 0.50" were forecast for Ventura County which was less than the observed amounts which were closer to 0.5" to 1.0". The storm lasted approximately eight hours.

Event 3 (Wet)

Rain for Event 3 began early in the morning on March 17, 2012. The remote programming capabilities were not operational for Event 3 due to issues with Verizon's Circuit Switched Data program. Pacing changes could not be made remotely and had to be made manually via the 6712 sampler pulse counts. Forecasts were between 0.75" and 1.5" with potential for up to 3" in the mountains. Rain amounts were relatively accurate, with 0.5" to 1.5" seen at most sites across the county over about 7 hours. Rain amounts and durations were a little higher in the Ojai Valley.

Event 4 (Dry)

The dry-weather sampling events took place over three days, on April 23, May 21, and May 23, 2012. Sampling was organized and conducted by major watershed. The Ventura River Watershed sites (ME-VR2, MO-OJA, and MO-MEI) were sampled on April 23, approximately 10 days after the last rainfall. Since MO-MEI is known to go dry relatively quickly after the end of the rain season, this watershed was sampled soon (but greater than seven days) after the last rain in order to be able to collect sample at this site. The Santa Clara River Watershed sites (ME-SCR, MO-FIL, MO-SPA, MO-OXN, and MO-VEN) were sampled on May 21, 2012, approximately one month after the last rainfall. MO-SPA had been dry for most of the month prior to the sampling event, including the preceding four days and stayed dry during the sampling event so samples could not be collected. The Calleguas Creek Watershed (ME-CC, MO-CAM, MO-SIM, MO-MPK, MO-THO) and Coastal Watershed (MO-HUE) were sampled two days later, on May 23, 2012. There was no flow at MO-MPK so samples could not be taken. Sampling duration at all sites was about 23 hours.

2012-DRY

The dry-season, dry-weather grab samples were collected from representative MS4 outfalls on two days, August 15 and 16, 2012. Fillmore-1 (MO-FIL), Ojai-1 (MO-OJA), Oxnard-1 (MO-OXN), Santa Paula-2 (Fagan Canyon), and Ventura-1 (MO-VEN) were sampled on August 15, 2012. Camarillo-1 (MO-CAM), Moorpark-1 (MO-MPK), Port Hueneme-3 (Bubbling Springs Park), Simi Valley-1 (MO-SIM), and Thousand Oaks-1 (MO-THO), and Unincorporated-2 (Medea Creek in Oak Park) were sampled on August 16, 2012. There was at least 72 hours of dry weather preceding each sampling event.

During the dry sampling events, Stormwater Monitoring Program staff deployed sand-weighted silicone dams where necessary to allow very low flows to pool up to sampleable depths. This provided the depth needed to submerge the grab bottles and/or automated sampler intake line to facilitate successful sample collection (see Figure 9-8). This innovative technique is further discussed in *Ventura Countywide Stormwater Monitoring Program: Water Quality Monitoring Standard Operating Procedures, 2009-2014*.

Figure 9-8. Typical Wet-Season, Dry-Weather Sampling Configuration

9.4.5 Analyses Performed

Attachment G of the Permit lists the constituents to be analyzed for each event⁸. In addition to this broad suite of analytes, Attachment B specifies other site-specific analytes that have been identified as problematic pollutants in

⁸ For Permit sections A. Mass Emission and B. Major Outfalls only. The constituents for Section C. Dry Weather Analytical Monitoring are listed separately in that section and are detailed in Section 9.7 of this report.

previous years of water quality sampling. These, and any unrequested analytes for which results are obtained during method analysis, were incorporated into the sampling program and appear in the tables below. Table 9-2 shows those analytes that were gathered as discrete samples.

Table 9-3 shows those analytes that were gathered as composite samples. All laboratory chemical analyses of environmental samples and pre-season equipment blank samples were performed by Weck Laboratories, with the exception of analyses for indicator bacteria, which were performed by the Ventura County Public Health Lab.

Table 9-2. Analytes Derived from Discrete Samples

9.4.6 Quality Assurance / Quality Control

The following is a discussion of the results of the quality assurance and quality control (QA/QC) analysis performed on the 2011/12 stormwater quality monitoring data. The data were evaluated for overall sample integrity, holding time exceedances, contamination, accuracy, and precision using field- and lab-initiated QA/QC sample results according to the Stormwater Monitoring Program's *Data Quality Evaluation Plan* and *Data*

Quality Evaluation Standard Operating Procedures. The *Data Quality Evaluation Plan* (DQEP) describes the process by which water chemistry data produced by the Stormwater Monitoring Program are evaluated. Data quality evaluation is a multiple step process used to identify errors, inconsistencies, or other problems potentially associated with Stormwater Monitoring Program data. The DQEP contains a detailed discussion of the technical review process, based on U.S. Environmental Protection Agency (EPA) guidance and requirements set forth by the Stormwater Monitoring Program used to evaluate water quality monitoring data. The DQEP provides a reference point from which a program-consistent quality assurance/quality control (QA/QC) evaluation can be performed by the Stormwater Monitoring Program. The *Data Quality Evaluation Standard Operating Procedures* (SOPs) document provides a set of written instructions that documents the process used by the Stormwater Monitoring Program to evaluate water quality data. The SOPs describe both technical and administrative operational elements undertaken by the Stormwater Monitoring Program in carrying out its DQEP. The SOPs act as a set of prescriptive instructions detailing in a step-by-step manner how District staff carry out the data evaluation and data quality objectives set forth in the DQEP. QA/QC sample results from the 2011/12 monitoring season are presented in Appendix F in Attachment E.

QA/QC sample collection and analysis relies upon QA/QC samples collected in the field (such as equipment blank, field duplicate, and matrix spike samples), as well as QA/QC samples prepared and analyzed by the analytical laboratory (i.e., lab-initiated samples, such as method blanks, filter blanks, and laboratory control spikes) performing the analysis. The actual chemical analysis of field-initiated and lab-initiated QA/QC samples is conducted in an identical manner as the analysis of field-collected environmental samples. After all analyses are complete, the results of the field-initiated and lab-initiated QA/QC sample results are compared to particular data quality objectives (DQOs), also commonly referred to as “QA/QC limits.” These limits are typically established by the analytical laboratory based on EPA protocols and guidance. However, in some cases, the Stormwater Monitoring Program will set a particular DQO, such as the QA/QC limit for field duplicate results.

QA/QC sample results are evaluated in order to compare them to their appropriate QA/QC limits and identify those results that fall outside of these limits. The QA/QC evaluation occurs in two separate steps as the laboratory will review those results that fall outside of its QA/QC limits and typically label these results with some type of qualification or note. If a QA/QC sample result falls grossly outside of its associated QA/QC limit, and thus indicates that there is a major problem with the lab’s instrumentation and/or analytical process, then the laboratory should re-run both the affected QA/QC and environmental samples as necessary. The second step in the QA/QC evaluation process occurs when the Stormwater Monitoring Program performs an overall sample integrity evaluation, as well as specific holding time, contamination, accuracy, and precision checks. This second evaluation step provides an opportunity to thoroughly review the Stormwater Monitoring Program’s data to identify potential errors in a laboratory’s reporting of analytical data and/or recognize any significant data quality issues that may need to be addressed. After this evaluation the Stormwater Monitoring Program is ready to qualify their environmental data as necessary based on the findings of the QA/QC assessment.

Data qualification occurs when the Stormwater Monitoring Program assigns a particular program qualification to an analytical result as a means to notify data users that the result was produced while one or more DQOs or QA/QC limitations were exceeded. Environmental sample results are qualified in order to provide the user of these data with information regarding the quality of the data. Depending on the planned use of the data, qualifications may help to determine whether or not the data are appropriate for a given analysis. In general, data that are qualified with anything other than an “R” (used to signify a rejected data point) are suitable for most analyses. However, the qualifications assigned to the data allow the user to assess the appropriateness of the data for a given use. The Stormwater Monitoring Program used its NDPES Stormwater Quality Database to conduct a semi-automated QA/QC evaluation of the current season’s data contained in the database. The use of the database allows the Stormwater Monitoring Program to expedite and standardize the QA/QC evaluation of its monitoring data in conjunction with the use of the DQEP and SOPs. After reviewing the qualifications assigned to each qualified data point in the 2011/12 monitoring year data set, the environmental data are considered to be of high

quality and sufficient for all future general uses. However, all data qualifiers should be reviewed and considered prior to the use of the data in a specific analysis or application. Environmental data from the 2011/12 monitoring season are presented in Appendix G.

Both environmental and field-initiated QA/QC samples were collected in the field using clean sampling techniques. To minimize the potential for contamination, Weck Laboratories cleaned all bottles used for composite samples. Only new containers were used for grab sample collection, with the appropriate preservative added to grab bottles by Weck. Intake lines for the automated samplers were flushed using distilled water. Designated sampling crew leaders were used to ensure that consistent sample collection and handling techniques were followed during every monitoring event.

Field-initiated QA/QC samples performed by the Stormwater Monitoring Program during the 2011/12 monitoring season included field blanks, field duplicates, and equipment blanks. Equipment blanks are typically prepared prior to the start of the monitoring season to check that tubing, strainers, and sample containers aren't sources of contamination for the Stormwater Monitoring Program's environmental samples. Tubing equipment blanks were collected from the sampling equipment by passing blank water through cleaned tubing and into brand new sample bottles. Composite bottle equipment blanks were collected by adding blank water to a composite bottle and allowing it to sit at 4°C for 24 hours before being split into brand new sample bottles for analysis. After collection, equipment blanks were submitted to the analytical laboratory and analyzed using the same methods as those employed for routine environmental sample analysis.

9.4.7 Equipment Blanks

Equipment blanks, often referred to as pre-season blanks, were collected prior to the monitoring season to test for contamination in sample containers (e.g., composite bottles) and sample equipment (e.g., intake lines, tubing, and strainers). This process consists of running laboratory-prepared blank water through sampler tubing to identify potential contamination of field-collected samples as a result of "dirty" tubing. The blank water (ultrapure deionized water) used to evaluate contamination of composite bottles and tubing can also be analyzed in order to check for contamination of this analytical sample medium. Equipment blank "hits" or measured concentrations above the laboratory's quantitation limit (RL, PQL, etc.) for a constituent are assessed and acted upon using the guidelines listed below:

1. The Stormwater Monitoring Program requests that the laboratory confirm the reported results against lab bench sheets or other original analytical instrument output. Any calculation or reporting errors should be corrected and reported by the laboratory in an amended laboratory report.
2. If the previous step does not identify improperly reported results, then the analytical laboratory should be asked to identify any possible sources of contamination in the laboratory.
3. If no laboratory contamination is identified, then a note should be made that documents that the equipment blank results indicate that the sample equipment may have introduced contamination into the blank samples.

When practical, remedial measures are initiated by the Stormwater Monitoring Program to replace or re-clean sampling equipment and re-analyze equipment blank samples in an effort to eliminate field contamination. Only the results of field-initiated and laboratory-initiated QA/QC samples associated with the environmental samples collected for any given monitoring event are used to qualify Stormwater Monitoring Program environmental samples. However, pre-season analyses provide useful information regarding possible sources of environmental sample contamination and insight into how contamination issues might be resolved.

Preseason equipment blank “Carboy Blank” (composite bottle) and “Tubing Blank (distilled)” (intake line cleaned with distilled water only) samples were collected for the 2011/12 monitoring year on August 25, 2011. The “Tubing Blank (distilled)” sample was collected through the intake line at MO-MEI after flushing the line with distilled water. The Carboy Blank samples were split off from ultrapure deionized water that had been added to a clean composite bottle and left to sit at 0 - 4 degrees Celsius for 24 hours. The blanks were analyzed by EPA 200.8 for total metals (iron by EPA 200.7), EPA 245.1 for total mercury, EPA 353.2 for nitrate + nitrite as nitrogen, and EPA 625 for semi-volatile organics.

Constituents that were either not detected or detected below the levels typically found in stormwater and therefore not a cause for concern in both the carboy and tubing blanks were: aluminum, chromium, iron, lead, zinc, and nitrate+nitrite. The amount of mercury detected in each of the equipment blanks (0.023 ug/L) was below the reporting limit and similar to the amount frequently seen in the laboratory’s method blanks, including the method blank for this batch (0.022 ug/L), so the levels could be due to laboratory contamination. Copper was detected in the tubing blank and carboy (DNQ) but below the levels typically found in stormwater, including levels detected in Event 1. Diethyl phthalate was not detected in the composite bottle but was detected in the tubing blank above the reporting limit and at the higher end of the spectrum of environmental results seen in stormwater analysis. However, the detected amount is well below the limit of 120,000 ug/L in the CTR.

Preseason 2 investigated three possible sources of the diethyl phthalate contamination. Samples of the distilled water used for flushing the lines (from each of the two different styles of plastic 5-gallon carboys, “Arrowhead (handle)” and “Arrowhead (old)”), and ultrapure water left for 24 hours in the 2 liter high density polyethylene container used for flushing the lines (“Rinse 2L (plastic)”) were tested by EPA 625. Bis(2-ethylhexyl) phthalate was detected in the Arrowhead (handle) sample above the reporting limit and above the amounts typically seen in stormwater, however almost double the amount seen in this sample was measured in the method blank, so the contamination is likely a laboratory issue. Two contaminants were seen in the Rinse 2L (plastic) sample: diethyl phthalate and di-n-butylphthalate, however both were below the reporting limit and well below the limits in the CTR. To ensure that the risk of contamination is reduced for future events, the Stormwater Monitoring Program purchased fluorinated HDPE 2L containers to replace the 2L HPDE rinse containers previously used by the Program.

Based on these results, the Stormwater Monitoring Program determined that cleaning procedures were adequate and no follow-up was necessary. Furthermore, no environmental samples were qualified by the Stormwater Monitoring Program based on the results of pre-season equipment blank analyses. The cleaning procedures will be reexamined during the preseason tests prior to the 2012/13 monitoring season.

Table 9-4. Constituents Detected in Equipment Blanks Before Event 1

Constituent	Tubing Blank (distilled) Concentration (µg/L)	Carboy Blank Concentration (µg/L)	Reporting Limit (µg/L)	Stormwater Range (when detected) Concentration (µg/L)
Preseason 1				Event 1
Aluminum	7.1	20	5	210 – 18,000
Chromium	0.089*	-	0.2	0.66 – 56
Copper	0.65	0.39*	0.5	1.8 – 120
Iron	4.2*	3.1*	10	910 – 30,000
Lead	0.02*	0.037*	0.2	0.26 – 34
Mercury	0.023*	0.023*	0.050	0.028* - 0.086
Zinc	1.7*	2*	1.1	3.5* – 370
Nitrate+Nitrite as N	-	23*	100	410 – 4,000
Diethyl phthalate	5.7	-	1	0.37* -3.1, 6.1**

Constituent	Arrowhead (handle)	Arrowhead (old)	Rinse 2L (plastic)	Reporting Limit	Stormwater Range (when detected)
	Concentration (µg/L)	Concentration (µg/L)	Concentration (µg/L)	(µg/L)	Concentration (µg/L)
Preseason 2					Event 2
Diethyl phthalate	-	-	0.42*	1	100 – 15,000
Di-n-butylphthalate	-	-	0.25*	1	<0.24 – 0.27*, <2.4
Bis(2-ethylhexyl) phthalate	6.9	-	-	5	<1.1 – 2.6*, <11

* DNQ

** Sample diluted so result is DNQ but reporting limit is higher than undiluted samples

9.4.8 Field and Laboratory Duplicates

Duplicate samples – both field duplicates and lab duplicates – are collected in the field using the same techniques as used for all environmental sample collection. For composite samples, a larger volume of water is collected during the monitoring event and then the duplicates are split in the field (when generating a field duplicate) or in the lab (when generating a lab duplicate) while constantly mixing the contents of the composite containers to ensure the production of homogeneous duplicate samples. The Stormwater Monitoring Program does not collect field duplicates for composite samples as samples are not split in the field due to the risk of sample contamination and breakage. In the case of grab samples, two samples are collected side-by-side or in immediate succession into separate sample bottles when collecting an environmental sample and its field duplicate. Depending on the volume of water required to perform a particular analysis, a lab duplicate analysis of a grab sample may require the collection of additional sample, or may be run on a single environmental sample.

Field duplicate grab samples were collected during Event 1 (MO-VEN) and Event 2 (bacteriologicals at MO-MEI, all others at MO-VEN). Laboratory-initiated laboratory duplicate samples were analyzed on non-project samples for Event 1 – 4. Results are shown in Table 9-5 and Table 9-6. Of the 73 laboratory duplicates, only one was outside the DQO so the overall success rate was 98.6%. Of the 16 field duplicate samples, only one was outside of the DQO and that was fecal coliform at MO-VEN in Event 1 so the field duplicate success rate was 93.8%.

Table 9-5. Field Duplicate Success Rates

Classification	Constituent	Method	Total Samples	Samples Outside DQO	Success Rate
Bacteriological	Total coliform / <i>E. coli</i>	MMO-MUG	4	0	100
Bacteriological	Fecal coliform	SM 9221 E	2	1	50
Conventional	Cyanide	EPA 335.4	2	0	100
Hydrocarbon	Oil and grease/TPH	EPA 1664A	4	0	100
Organic	Various	EPA 524.2	4	0	100

Table 9-6. Laboratory Duplicate Success Rates

Classification	Constituent	Method	Total Samples	Samples Outside DQO	Success Rate
Conventional	Volatile Solids	Suspended EPA 160.4	9	0	100

Conventional	pH	SM 4500-H+ B	1	0	100
Pesticide	Glyphosate	EPA 547	1	0	100

9.4.9 Holding Time Exceedances

The large majority of analytical methods used to analyze water quality samples specify a certain time period in which an analysis must be performed in order to ensure confidence in the result provided from the analysis.¹⁰ A holding time can be either the time between sample collection and sample preparation (the preparation holding time limit) or between the sample preparation and sample analysis (the analysis holding time limit). If a particular sample doesn't require any pre-analysis preparation, then the analysis holding time is the time between sample collection and sample analysis.

These elapsed times are compared to holding time values (typically provided in EPA guidance for analytical methods) to determine if a holding time exceedance has occurred. Elapsed times greater than specified holding time limits are considered to exceed the Stormwater Monitoring Program's DQO for this QA/QC sample type. All holding times were met by laboratories during the 2010/11 monitoring season, with the exceptions as shown in Table 9-7.

Table 9-7. Holding Time Success Rate

Classification	Total Samples	Samples Outside DQO	Success Rate
Anion	162	0	100
Bacteriological	144	0	100
Cation	130	0	100
Conventional	729	18 ^a	97.5
Hydrocarbon	18	0	100
Metal	1779	0	100
Nutrient	438	0	100
Organic	4945	45 ^b	99.1
PCB	378	0	100
Pesticide	5460	0	100

¹⁰ A sample that remains unanalyzed for too long a period of time sometimes shows analytical results different from those that would have been observed had the sample been analyzed earlier in time. This difference is due to the breakdown, transformation, and/or dissipation of substances in the sample over time.

^a Total chlorine residual is a Pollutant of Concern for ME-CC due to the contributions of wastewater treatment plants. The method requires that this constituent be analyzed “immediately” and the permit requires that it be sampled as a composite sample, which combined to result in an exceedance of the hold time for each event. The laboratory analyzed a composite sample from each site for pH although it was not requested on the COC. The holding time for pH is 15 minutes so the samples were analyzed outside of this limit.

^b Two samples were extracted outside of the holding time, affecting 16 constituents. One site was extracted and analyzed within the holding time but required a dilution and re-analysis for 29 constituents which was performed outside of the holding time.

9.4.10 Dilutions

Due to the nature of stormwater matrices, some samples required dilutions prior to analysis. Of the 888 samples that were only qualified due to a dilution, 253 were at or above the reporting level and so were not adversely affected by the raised method detection and reporting limits associated with sample dilution. These samples are considered by the Program to have met all DQOs.

9.4.11 Other QA/QC Methods and Analyses

A variety of other QA/QC methods are used by the Stormwater Monitoring Program and associated laboratories to determine the quality of the data. These include method blanks, matrix spikes and matrix spike duplicates (MS/MSD), surrogate spikes, and laboratory control samples. For many of these, the relative percent difference between two separate samples is computed to determine whether or not the laboratory has achieved the necessary DQO, as described in Section 9.4.6. Results of QA/QC analyses performed on individual samples can be found in Appendix F and Appendix G in Attachment E.

9.4.12 QA/QC Summary

In summary, a total of 11,812 environmental samples were analyzed during the 2011/12 monitoring season. Of these, 10,851 met all DQOs for that particular sample. The Stormwater Monitoring Program’s QA/QC evaluation process identified 961 environmental samples in need of qualification, which translates into the Stormwater Monitoring Program achieving a 91.8% success rate in meeting program data quality objectives. No samples were rejected from the dataset. Received

Overall, the three wet-weather and two dry-weather events monitored per site during the 2011/12 monitoring season produced a high quality data set in terms of the low percentage of qualified data, as well as the low reporting levels achieved by the laboratories analyzing the Stormwater Monitoring Program’s water quality samples.

9.5 WATER QUALITY RESULTS

The NDPES permit requires the Stormwater Monitoring Program to report the results of stormwater monitoring to the Regional Board in two ways. First, within 90 days of a monitoring event, analytical results must be submitted electronically and must highlight elevated constituent levels relative to Basin Plan and CTR acute criteria. The Stormwater Monitoring Program met this requirement for all monitoring events during the 2011/12 season. Second, an Annual Storm Water Report must be submitted by December 15th, and must highlight those same elevated levels relative to applicable water quality objectives. The contents of this report fulfill that requirement.

For the analysis of wet-weather data (Events 1-3), the Basin Plan objectives and the acute, freshwater objectives in the CTR were used. For some constituents, the California Toxics Rule does not contain acute objectives. Previously, and in this monitoring year’s 90 day event reports, the Stormwater Monitoring Program used the

California Toxics Rule Human Health (Organisms Only) objectives for these cases because these constituents had no other objectives for comparison. However, since these objectives are based on long-term exposure and stormwater discharges are of short duration, it was decided that comparing short term stormwater discharges to the long-term chronic criteria was not an accurate representation of the risk of stormwater discharges to Human Health. CTR chronic criteria were not used for wet-weather analyses because acute criteria better reflect the short-term storm event exposure experienced by organisms, as compared to the long-term exposure considered by chronic criteria.

For the analysis of dry-weather data (Event 4), the Basin Plan objectives and the most stringent of the CTR chronic freshwater objectives (Criterion Continuous Concentration), CTR Human Health (Organisms Only), or CTR Human Health (Water & Organisms) were used. Previously, if the CTR did not contain chronic freshwater objectives for a constituent, the CTR Human Health (Organisms Only) was used. In evaluating the criteria, the Stormwater Monitoring Program determined that the MUN designation in the Basin Plan indicates that Human Health Criteria should be considered in evaluating dry-weather exceedances due to their potential for long-term exposure.

The rationale and consequences of this year's changes related to the application of CTR numerical objectives to wet- and dry-weather data are discussed in Section 6.2.

For all events, objectives in the CTR for metals were calculated based on the hardness of the water. This analysis used the hardness value measured at a particular site during a particular monitoring event for calculating a certain metals objective, except when the measured hardness was greater than 400 mg/L. The CTR sets a hardness cap of 400 mg/L for calculating the objectives, so any measured hardness value above 400 mg/L was set equal to 400 mg/L for the purposes of the calculation.

This section presents an evaluation of the data with these water quality objectives (WQOs) and serves, together with the entirety of this Annual Report, as the Receiving Water Limitations report required in Section 3a of Part 2 of the Permit.

9.5.1 Re-evaluation of application of CTR numeric criteria to receiving waters

In previous years, the CTR Numeric Criteria were applied as described on page 30 of the 2010-2011 Water Quality Monitoring Report (Ventura Countywide Stormwater Quality Management Program Annual Report, Attachment F):

“For the analysis of wet-weather data ..., the Basin Plan objectives and the acute, freshwater objectives in the CTR were used. For some constituents, the California Toxics Rule does not contain acute objectives. In these cases, the California Toxics Rule Human Health (Organisms Only) objectives were used in the wet-weather comparison because these constituents have no other objectives for comparison. These objectives were used even though they are based on long-term risks to human health that cannot be directly correlated to stormwater discharges. CTR chronic criteria were not used for wet-weather analyses because acute criteria better reflect the short-term storm event exposure experienced by organisms, as compared to the long-term exposure considered by chronic criteria.

For the analysis of dry-weather data ..., the Basin Plan objectives and the chronic, freshwater objectives in the CTR were used. For some constituents, the CTR does not contain chronic objectives. In these cases, the CTR Human Health (Organisms Only) objectives were used in the dry-weather comparisons because these constituents have no other objectives for comparison.”

However, application of the CTR criteria as detailed above, resulted in inconsistent application of acute and chronic criteria, and inconsistent protection of beneficial uses. For instance, during wet weather the Criterion

Maximum Concentration (CMC) of 1.1 µg/l is applied for 4,4'-DDT, while the Human Health criterion of 0.00059 µg/l is applied for 4,4'-DDE, because a CMC is not listed for the latter. In addition, the selection of the CTR Human Health (Organisms Only) criterion appears inappropriate given that the Ventura County mass emission stations have MUN designated beneficial uses. Therefore, the CTR Human Health (Water + Organisms) criteria are more appropriate.

The new approach to identify water quality exceedances continues to compare the EMC (which for this purpose is the concentration measured in the composite or grab sample collected during the event, as applicable) to water quality standards and can be summarized as follows:

- 1) Wet weather: CTR CMC and Basin Plan criteria apply. The most stringent criterion is used for each constituent in order to identify water quality exceedances. If CMC criteria are not available, no other CTR criteria are substituted.
- 2) Dry weather: all CTR and Basin Plan criteria apply. The most stringent criterion is used for each constituent in order to identify water quality exceedances.

This approach constitutes an improvement over the approach used prior to this year, because:

- Numerical criteria are now consistently applied for all constituents.
- Chronic criteria are not applicable to short-lived storm events. CTR Criterion Continuous Concentrations (CCCs) and Human Health criteria are expressed as 4-day maxima and 30-day averages, and therefore their application to storm events of less than 24 hours is questionable.
- Based on a poll among the Southern California Stormwater Monitoring Coalition (SMC) members, the new approach is in line with the approach taken by most other stormwater agencies in southern California.

Historical data between 2007 and 2012 were analyzed to determine the potential practical impact of the new approach in identifying water quality exceedances at mass emission stations, compared to how exceedances have been reported in the past. In summary, the new approach led to:

- Elimination of wet weather exceedances for total mercury, benzo(a)anthracene, benzo(b)fluoranthene, benzo(k)fluoranthene, indeno(1,2,3-cd)pyrene, chrysene, 4,4'-DDD and 4,4'-DDE, since CTR human health criteria no longer apply and no other numerical criteria are available.
- Elimination of wet weather exceedances for benzo(a)pyrene due to increase of numerical criterion from 0.049 µg/l (CTR human health, organisms only) to 0.2 µg/l (Basin Plan MCL).
- Increase in dry weather exceedances for bis(2-ethylhexyl)phthalate due to decrease of numerical criterion from 4 µg/l (Basin Plan) to 1.8 µg/l (CTR human health, water + organisms).
- Increase in dry weather exceedances for chrysene and benzo(b)fluoranthene due to decrease of numerical criteria from 0.049 µg/l (CTR human health, organisms only) to 0.0044 µg/l (CTR human health (water + organisms)).

The above analysis retrospectively identified the constituents that were affected by our new approach to determining water quality exceedances. It is reasonable to assume that the implications for the future will be similar. However, this has changed numerical criteria for many other constituents as well, but there were no practical implications for the number of exceedances seen in the 2007 – 2012 data.

9.5.2 Water Quality Objective Exceedances and Elevated Levels

Table 9-8 presents water quality objective exceedances at Mass Emission stations based on an analysis of the 2011/12 wet-season stormwater monitoring data. Constituents that were found at elevated levels¹¹ at sites upstream (i.e., related Major Outfall stations) are shown in bold and highlighted (see Section 9.5.7 through Section 9.5.9 for a discussion of the relationship between the Mass Emission and Major Outfall stations). Table 9-9 presents the elevated levels of constituents at Major Outfall stations based on an analysis of the 2011/12 wet-season stormwater monitoring data. Constituents that exceeded the water quality objective at sites downstream (i.e., related Mass Emission stations) are shown in bold and highlighted (again, see Section 9.5.7 through Section 9.5.9 for a discussion of the relationship between the Mass Emission and Major Outfall stations).

9.5.3 Ventura River Mass Emission Station (ME-VR2) Water Quality Objective Exceedances and Elevated Levels Corrections

The Ventura River Mass Emission station (ME-VR2) was installed during the 2004/05 monitoring year when the original station, ME-VR was decommissioned due to safety concerns as a result of landslide activity. The station was moved approximately one mile downstream to a safe location, while still representative of the runoff of the Ventura River watershed. The new location for the station put it into a different reach of the river according to the Basin Plan (between the confluence with Weldon Canyon and Main Street rather than between Casitas Vista Road and the confluence with Weldon Canyon), with higher limits for total dissolved solids (TDS), sulfate, chloride, boron, and nitrogen. Of these constituents, TDS, chloride, and nitrogen are monitored as part of the NPDES permit by the Stormwater Monitoring Program. The limits in the Program's database were not updated for the new location until the 2011 annual report, and they are now correct for the current location. These changes and revised exceedances were explained in the 2011 annual report.

9.5.4 Salinity Results Correction for Units

While salinity is not a constituent that is required by the permit, it is measured in the field by field crews and has been reported since Event 1 in the 2009/10 monitoring year. The YSI 85 field meter provides the salinity results in units of ppt but the database stores the data in mg/L, the equivalent of ppm (parts per million). The abbreviation ppt was incorrectly translated as parts per trillion instead of parts per thousand. The error was noticed in December 2012 and all data has been updated. Event data submitted in the 2009/10, 2010/11, and 2011/12 monitoring years and the 2009/10 and 2010/11 Annual reports contained the incorrectly translated values. The salinity data in the database and the 2011/12 Annual Report now contain the correct values. This correction does not affect past results reported for the Permit required constituents traditionally categorized as salts: boron, chloride, sulfate, and total dissolved solids.

9.5.5 Urban Runoff Impacts on Receiving Waters

Pursuant to Part 2 of the Permit, the Permittees are required to determine whether discharges from their municipal separate storm sewer systems are causing or contributing to a violation of water quality standards (WQS). Additionally, Permittees are responsible for preventing discharges from the MS4 of stormwater or non-

¹¹ "Elevated levels" is used to describe those concentrations that are above a particular water quality standard. These amounts are not referred to as "exceedances," as has been done for the Mass Emission stations, since, technically, those standards are only applicable to receiving waters, not to the outfalls that were monitored.

stormwater from causing or contributing to a condition of nuisance. Specifically, the Order contains following Receiving Water Limitations Language:

1. Discharges from the MS4 that cause or contribute to a violation of water quality standards are prohibited.
2. Discharges from the MS4 of stormwater, or non-stormwater, for which a Permittee is responsible, shall not cause or contribute to a condition of nuisance.

Compliance with the above Receiving Water Limitations is achieved by the Permittees through implementation of control measures and other actions to reduce pollutants in stormwater and non-stormwater discharges in accordance with the requirements of the Permit. The following section presents a discussion of WQS exceedances that occurred during the three wet-weather and one dry-weather monitoring events during the 2011/12 monitoring year.

9.5.6 “Cause or Contribute” Evaluation Methodology

The evaluation used to determine if a pollutant is persistently causing or contributing to the exceedance of a WQS in receiving waters consists of three steps:

1. The water quality data collected at a mass emission site in the same watershed is used as the receiving water to compare to relevant WQS contained in the CTR and Basin Plan (Section 9.5.1).
2. When a receiving water concentration exceeded a WQS for a particular constituent, the urban runoff concentration of said constituent measured at a Major Outfall in that watershed was compared to the WQS. If an elevated level relative to the associated WQS for said constituent was observed in both urban runoff and the receiving water, then the WQS exceedance in the receiving water was determined “likely caused or contributed to by urban runoff.” However, this comparison does not consider the frequency or persistence of WQS exceedances for a given constituent.
3. The persistence of a WQS exceedance was determined by evaluating the number of times (frequency) that a constituent was observed at an elevated level in urban runoff and in excess of the WQS for the receiving water for a particular type of monitoring event (wet or dry) over the course of the monitoring season. If two or more elevated levels in urban runoff and WQS exceedances in the receiving water were observed for a particular constituent over the course of the monitoring season, then the WQS exceedances of said constituent were determined to be persistent. Ideally, an assessment of persistency would be based on a larger data set (e.g., 10 events or more) and an assumed percentage of exceedances (e.g., 50%), but given the need for an annual assessment two or more exceedances from the existing, limited data set were used as the criterion to determine persistence.

9.5.7 Ventura River Watershed Receiving Water Limit Evaluation

Urban stormwater runoff and urban non-stormwater flows were evaluated at two Major Outfall locations in the Ventura River Watershed during the 2011/12 season: Meiners Oaks-1 (MO-MEI) and Ojai-1 (MO-OJA). Both of these Major Outfalls are located upstream of the ME-VR2 Mass Emission station (see Figure 9.1), and therefore water quality data collected at ME-VR2 were used to represent receiving water quality in the “cause or contribute” evaluation conducted for both Major Outfalls. Table 9-10 and Table 9-11 show the constituents that exceeded WQS in the downstream receiving water and compares them to the levels measured at the Major Outfalls, MO-MEI and MO-OJA, respectively. Receiving water exceedances with corresponding WQS Major Outfall here the urban runoff from both the Major Outfalls were also outside of the WQS are in bold. Receiving water exceedances where the urban runoff from the applicable Major Outfalls was outside of WQS are shown in bold.

Table 9-10: Comparison of MO-MEI and ME-VR2 Relative to Water Quality Standards

Constituent (Unit)	Meiners Oaks-1 Major Outfall (MO-MEI)	Receiving Water (ME-VR2)	Water Quality Standard (Basin Plan or CTR)	
2011/12-1 (Wet) – Oct. 5, 2011

2011/12-3 (Wet) – Mar 17, 2012				
E. coli (MPN/100 mL)	24,192	5,475	235	BP
Fecal Coliform (MPN/100 mL)	30,000	5,000	400	BP

9.5.8 Santa Clara River Watershed Receiving Water Limit Evaluation

Urban stormwater runoff and urban non-stormwater flows were evaluated at four Major Outfalls in the Santa Clara River Watershed during the 2011/12 season: Fillmore-1 (MO-FIL), Santa Paula-1 (MO-SPA), Oxnard-1 (MO-OXN), and Ventura-1 (MO-VEN). Two of these stations, MO-FIL and MO-SPA, are located upstream of the ME-SCR Mass Emission station (see Figure 9.1), and therefore water quality data collected at ME-SCR were used to represent receiving water quality in the “cause or contribute” evaluation conducted for both Major Outfalls. The other two stations, MO-OXN and MO-VEN, are located downstream of the ME-SCR Mass Emission station (see Figure 9.1). Because the ME-SCR station is located upstream of MO-OXN and MO-VEN, an assumption was required so that water quality data collected at ME-SCR could be considered to adequately represent Santa Clara River water quality downstream of the confluence of both MO-OXN and MO-VEN with the river. For comparison purposes it was assumed that pollutant concentrations in the Santa Clara River downstream of ME-SCR remain the same as those measured at ME-SCR to a hypothetical compliance point below the confluence of MO-OXN and MO-VEN and the Santa Clara River. With this assumption in effect, water quality data collected at ME-SCR were used to represent receiving water quality in the “cause or contribute” evaluation conducted for the MO-OXN and MO-VEN stations. Constituents exceeding WQS at the receiving water were compared to the urban runoff levels at the MO-FIL, MO-SPA, MO-OXN, and MO-VEN stations and are shown in Table 9-12 through Table 9-15 below. Receiving water exceedances where the urban runoff from the applicable Major Outfalls was outside of WQS are shown in bold.

Table 9-12: Comparison of MO-FIL and ME-SCR Relative to Water Quality Standards

Constituent (Unit)	Fillmore-1 Major Outfall (MO-FIL)	Receiving Water (ME-SCR)	Water Quality Standard (Basin Plan or CTR)

9.5.9 Calleguas Creek Watershed Receiving Water Limit Evaluation

Urban stormwater runoff and urban non-stormwater flows were evaluated at four Major Outfalls in the Calleguas Creek Watershed during the 2011/12 season: Camarillo-1 (MO-CAM), Moorpark-1 (MO-MPK), Simi Valley-1 (MO-SIM), and Thousand Oaks-1 (MO-THO). Three of these Major Outfalls (MO-MPK, MO-SIM, and MO-THO) are located upstream of the ME-CC Mass Emission station (see Figure 9.1), and therefore water quality data collected at ME-CC were used to represent receiving water quality in the “cause or contribute” evaluation conducted for these Major Outfalls. As stated earlier, MO-CAM is located in a different subwatershed than the closest receiving water location, the ME-CC station, monitored by the Program (see Figure 9.1). MO-CAM is tributary to Revolon Slough, which is tributary to Calleguas Creek several miles downstream of ME-CC. Similar to the ME-SCR station in the Santa Clara River watershed, an assumption was made so that water quality data collected at ME-CC could be considered to adequately represent Calleguas Creek water quality downstream of the confluence of Revolon Slough and the creek. It was assumed that pollutant concentrations in Calleguas Creek downstream of ME-CC remain the same as those measured at ME-CC to a hypothetical compliance point below the confluence of Revolon Slough and Calleguas Creek. With this assumption in effect, water quality data collected at ME-CC were used to represent receiving water quality in the “cause or contribute” evaluation conducted for the MO-CAM Major Outfall. Constituents exceeding WQS at the receiving water were compared to the urban runoff levels at the MO-MPK, MO-SIM, MO-THO, and MO-CAM stations and are shown in

Table 9-16,

Table 9-17, Table 9-18, and Table 9-19 below. Receiving water exceedances where the urban runoff from the applicable Major Outfalls was outside of WQS are shown in bold.

9.5.1 Coastal Watershed

Urban stormwater runoff and urban non-stormwater flows were evaluated at one Major Outfall station that does not have an associated Mass Emissions station located within the watershed. The MO-HUE station is located in Port Hueneme and discharges to the J Street Drain just upstream of where the drain enters the Ormond Beach lagoon. The elevated levels seen at MO-HUE are listed in Table 9-9 and not in a separate table as there is not a Mass Emission station nearby to which comparisons would be relevant.

9.5.2 Discussion of Results above Water Quality Standards

Aluminum, *E. coli* and fecal coliforms were commonly found at elevated levels at most sites during wet-weather events, but with the exception of *E. coli*, rarely during dry-weather events. Other constituents that were found at elevated levels during the 2011/12 monitoring season include chloride and total dissolved solids (predominantly during the dry-weather event); dissolved oxygen; dissolved copper; and pH (dry weather). Constituents that were seen at elevated levels at Major Outfalls only once during the season include total chromium, bis(2-ethylhexyl)phthalate, benzo(a)pyrene, and pentachlorophenol. Constituents that were seen at elevated levels at Mass Emission stations only once during the season include the metals (total) barium, cadmium, chromium, and nickel. The Program is using this information to identify pollutants of concern and direct efforts to reduce their discharge from the storm drain system.

Pathogen Indicators

Urban runoff concentrations of *E. coli* and fecal coliform bacteria were detected above their respective Basin Plan objectives during all three wet weather events at all but one Major Outfall station during the 2011/12 season, with the exception being MO-FIL during Event 2, where *E. coli* and fecal coliform bacteria were both below the objectives. Wet weather receiving water exceedances were less consistent, with all three sites above the objectives for both *E. coli* and fecal coliform bacteria during Event 1, two sites (ME-CC and ME-VR2) exceeding the fecal coliform bacteria objectives for Event 2 and one site (ME-VR2) for Event 3. The *E. coli* objectives were exceeded during Event 2 at ME-CC and Event 3 at ME-SCR and ME-VR2. These indicator bacteria are routinely measured at concentrations in excess of WQS during wet weather events. The story improves, however, with regard to dry weather monitoring during the 2011/12 season. No dry weather bacteria exceedances were observed at any of the receiving water stations. The majority of Major Outfall stations exhibited concentrations of fecal indicator bacteria above Basin Plan objectives during dry weather monitoring. The exceptions include no elevated levels observed for MO-CAM, MO-OXN, and MO-VEN during Event 4. A lack of flow at MO-MPK and MO-SPA precluded dry event sample collection at these sites.

However, the elevated levels are not reflected in the water quality of the beaches. The results of the Beach Water Quality Monitoring Program in Ventura County has been outstanding with Heal the Bay's 2012 *End of Summer Beach Report Card* stating "Overall water quality at beaches throughout Ventura County remains among the best in the state. All monitored beaches received A grades in this report."

The stormwater program has in place control strategies that directly address indicator bacteria concentrations in urban runoff. The existing Program includes a comprehensive residential public outreach program that uses radio, newspaper, online banners, outdoor bulletins, and transit shelters to educate the public about preventing animal waste from entering storm drains. The pollutant outreach campaign was expanded in 2009 to include the mailing of a brochure to horse owners, equestrians and horse property owners. The brochure identified BMPs that horse owners should take to reduce bacteria in stormwater runoff. In 2012, County of Ventura and Ventura County Resources Conservation District initiated an outreach effort to horse and livestock owners in Ventura River Watershed to educate about water quality issues and encourage implementation of best management practices to reduce nutrient and bacteria loads from their discharge. Finally, the Program also conducts outreach to reduce bacteria and nutrients in runoff from pet waste. Section 3 - Public Outreach describes in detail the outreach conducted during the 2011/12 year. The Permittees install dispensers for pet waste pickup bags at beaches, parks and trail heads. It is estimated that over 2 million pet waste bags are given out each year and there are now close to 400 pet waste bag dispensers throughout the County encouraging pet owners to pick up after their pets.

The efforts of the Illicit Discharges/Illicit Connections Program also help to reduce bacteria in stormwater runoff by identifying and stopping illicit wastewater discharges. Eliminating illicit discharges not only protects water quality by eliminating the bacteria in the discharge, but also eliminates the ability for the discharge to pick up and transport bacteria on its way to the storm drain system. The indicator bacteria are also found to thrive in natural environments and sediments. The prevention of the transport of sediments includes steps to remove sediment

from the storm drain system through street sweeping, catch basin cleaning, debris basin maintenance and publicly owned BMPs. Industrial and commercial inspections, construction inspection, and illicit discharge response and elimination represent significant efforts towards eliminating the discharge metals. These are covered respectively in Section 7 - Public Agency Activities, Section 4 Industrial/Commercial Facilities Programs, Section 6 - Development Construction, and Section 8 - Illicit Connections and Illicit Discharges Elimination. Some Permittees conducted field efforts to track bacteriological contamination detected at the Major Outfalls. General conclusions were that the data evaluation did not indicate specific sources as elevated concentrations were determined throughout the tested subwatershed areas.

In addition to the municipal stormwater program, bacteria are being addressed through the TMDL programs in Malibu Creek, Miscellaneous Ventura Coastal Watersheds (Hobie and Kiddie Beaches), and Santa Clara River. Various reaches of Calleguas Creek and Ventura River are listed on the Section 303(d) list due to indicator bacteria impairment. The Malibu Creek and Ventura Coastal beaches Bacteria TMDLs have been in effect since January 24, 2006 and December 18, 2008, respectively. Implementation Plans for both dry-weather and wet-weather were prepared and submitted for both TMDLs and compliance monitoring has been conducted at Malibu Creek and Ventura Coastal beaches since 2007 and 2009, respectively. The Santa Clara River Bacteria TMDL went into effect on March 21, 2012 and a compliance monitoring plan and TMDL implementation plan are under development by the responsible parties according to the TMDL schedule. Addressing bacteriological impairments in the watershed is a challenging task. A number of BMPs implemented in Calleguas Creek and Ventura River watersheds to meet compliance with other TMDLs also address bacteriological impairment such as prohibition of illicit discharge or implementation of LID/Green Street retrofits. Calleguas Creek TMDL MOA group developed a draft Bacteria Work Plan to address this problematic pollutant in the Calleguas Creek Watershed.

Bacteriological contamination is a common occurrence throughout California and the United States. However, it is a challenging task to determine the actual impact to beneficial uses and levels causing human health risk during recreational activities in a watershed. The water quality monitoring standards are based on indicator organisms, not the actual pathogenic bacteria. As a result, it is difficult to ascertain whether a particular water concentration of mostly non-pathogenic indicator bacteria will cause human illness. Adding to the complexity is the fact that wildlife and other naturally occurring sources contribute to bacterial sources. Naturally occurring sources of bacteria have the potential to impact human health, but are extremely difficult to control.

Developing control measures to reduce observed bacteria concentrations to meet water quality standards is challenging. Treatment measures to address bacteria are likely to be costly and difficult to implement (especially with respect to infrequent and short-term, but high volume events that compose stormwater runoff). As a result, implementing measures that will result in compliance with the existing water quality objectives at all times will be extremely difficult. Consequently, the tasks in the Calleguas Creek Draft Bacteria Work Plan are designed to address these complexities to the greatest extent possible and provide mechanisms for protecting the identified beneficial uses in the watershed as is feasible. The strategy outlined in this draft work plan will assess the beneficial uses and risks to human health from bacteria and use that information to develop a TMDL to address bacteriological impairments. In the near-term an educational program focusing on the requirements of local domestic animal waste ordinances and the effects of domestic animal waste on the watershed is being considered¹². Like the metals TMDL, it is expected that the results from the bacteria TMDL will assist the municipal stormwater program in addressing this problematic pollutant because the successful efforts in Calleguas Creek can be applied throughout the County to address indicator bacteria.

¹² <http://www.calleguascreek.org/ccwmp/4f.asp> November 3, 2011.

As a means to better refine the implementation of BMPs that might result in additional reductions of indicator bacteria, the Permittees are evaluating source identification monitoring at Major Outfalls. This may include source tracking through additional sampling for indicator species or using Bacteroidales genetic markers to identify the source(s) of fecal bacteria. Such an approach was used in the Calleguas Creek watershed as part of the draft TMDL Work Plan initial monitoring effort where a source identification study was performed and modeling to allow evaluation of BMPs. Knowing what bacteria sources – agriculture (horse and/or cow), humans, dogs, and birds – are responsible for the high levels of indicator bacteria measured during storm events will assist in the selection of BMPs better suited to control a particular bacteria source. During summer of 2012, County of Ventura and VCWPD worked with SCCWRP to conduct a comprehensive water quality monitoring to determine bacteria sources and to assess the risk to swimmers' health recreating at Hobie and Kiddie beaches. The human markers were detected and additional work is being conducted to further reduce and eliminate anthropogenic sources.

These complex issues related to bacteriological contamination and impairment of beneficial uses have been considered and still need to be discussed among the regulators, regulated communities, and environmental groups with a goal to identify cost-effective water quality protective solutions in the near future.

Trace Metals

Aluminum

Urban runoff and receiving water concentrations of aluminum were found above the 1,000 µg/L Basin Plan objective at the majority of Major Outfall stations for one or more wet weather monitoring events during the 2011/12 season. Similarly, aluminum concentrations above the Basin Plan objective were measured at the ME-CC and ME-SCR receiving water stations during one or more wet events. Receiving water stations ME-CC and ME-SCR yielded aluminum results above WQO during the three wet weather monitoring events (Events 1-3) but not during the one dry weather monitoring event (Event 4) conducted during the current monitoring season. Major Outfall stations not showing wet weather aluminum above the WQS in the Calleguas Creek Watershed include MO-CAM (Event 2) and MO-SIM (Event 2); and in the Santa Clara River Watershed include MO-FIL (Events 1-3) and MO-OXN (Event 2). The only receiving water station not showing wet weather exceedances for aluminum was ME-VR2 (all wet events). A summary of those monitoring sites where aluminum concentrations were observed above the Basin Plan objective is shown in Table 9-21.

Since the Program began monitoring for aluminum in 2004, it has frequently observed elevated levels of the Basin Plan objective for the metal at all Program monitoring sites (receiving water and land use). Aluminum is found as a ubiquitous natural element in sediments throughout Ventura County geology. These sediments are mobilized during stormwater runoff events from urban, agriculture, and natural sources resulting in concentrations of aluminum in excess of the Basin Plan objective. This is clearly shown by the highly elevated wet weather concentrations of the metal measured in all three watersheds monitored by the Program. Similar to the current season, dry weather aluminum concentrations observed above WQS during the past eight years have only been observed a limited number of times. With elevated levels of aluminum co-occurring in both urban runoff and receiving waters within the same watershed during the same monitoring event, it is likely that concentrations of aluminum in urban runoff can be considered contributing to the elevated level observed in receiving waters.

Aluminum is a natural component of silt and clay, and concentrations in Southern California soils routinely exceed 3% (30,000 µg/g).¹³ In addition, wet-weather total aluminum concentrations are significantly correlated

¹³ Shacklette, H. T. and Hansford, J. G. (1984). Elemental concentrations in soils and other surficial materials of the conterminous United

with Total Suspended Solids (TSS) concentrations. Given that a TSS concentration of 500 mg/L result in an aluminum concentration of 15,000 µg/L in the water column, assuming all TSS originate from natural soils, it is reasonable to conclude that aluminum exceedances can readily be caused by erosion of the natural landscape.

Table 9-21 Aluminum detected above Basin Plan Objective

Aluminum detected above Basin Plan Objective

Dry – Not sampled during this event due to insufficient flow at site				

Copper

Based on the “cause or contribute” methodology, copper from urban outfalls was not determined to be a persistent cause or contribution of WQS exceedances. Elevated levels compared to the hardness-based CTR objective for dissolved copper were observed at Major Outfall stations during both wet and dry monitoring events: MO-CAM (Events 1-3), MO-MEI (Event 2), MO-MPK (Event 2), MO-OXN (Events 1-3), MO-SPA (Events 1-3), and MO-VEN (Events 2 and 4). No results above the CTR criterion for dissolved copper were observed at the receiving water stations during the 2011/12 season. Because results for copper were not observed above the CTR criterion in receiving waters (i.e., measured at the receiving water stations), there is no evidence to conclude that copper in urban runoff appreciably impacted receiving water beneficial uses during the 2011/12 monitoring season.

This conclusion does not mean these data will be ignored by the Program as it is actively addressing copper. Permittees supported the Brake Pad Partnership and Senate Bill (SB) 346 adopted September 27, 2010 – that authorized legislation to phase out the copper contained in vehicle brake pads. SB 346, authored by Senator Christine Kehoe (D-San Diego), requires brake pad manufacturers to reduce the use of copper in brake pads sold in California to no more than 5% by 2021 and no more than 0.5% by 2025. This true source control action will help significantly reduce copper in urban runoff. Several of the Major Outfall sites are next to freeways or railroad lines (MO-CAM, MO-OXN, MO-SPA, and MO-VEN)) where copper-containing dust from vehicles and trains is continually produced and deposited; the SB346 legislation will help address this issue. In the future, similar legislation to address train brake pads may help to further reduce copper in runoff.

Mercury

This year, the Program revised the method in which data is compared to CTR criteria, including the objectives for mercury. Previously, the Program used the Basin Plan Objectives (wet and dry weather), and CTR acute freshwater criteria (wet weather) or CTR chronic freshwater criteria (dry weather) to analyze the data. For constituents without a CTR freshwater objective, the CTR Human Health (Organisms Only) objectives were used. The updated method continues to compare wet weather results to the freshwater acute criteria but if the constituent does not have an acute criterion, the chronic Human Health criteria are no longer used because they are based on long term, continuous exposure, which is inappropriate for storm water. For dry weather, chronic criteria are appropriate so the data is compared to the most stringent of the CTR chronic freshwater, Human

Health (Water & Organisms), or Human Health (Organisms Only). This revision more accurately reflects the MUN designation of the outfalls and receiving waters.

No elevated mercury levels were observed above the Basin Plan Objective (2000 ng/L) at any of the major outfalls or receiving water stations during wet and dry weather for the 2011/12 season. The CTR does not have a freshwater acute criterion for mercury, so there were no wet weather mercury exceedances of the CTR. There were also no exceedances of the most stringent CTR chronic criteria (Human Health – Water & Organisms) during dry weather. Based on the findings of this season, the Program does not consider mercury at this time to constitute a persistent pollutant in urban runoff that is causing or contributing to impairments of beneficial uses in the Ventura River Watershed, Santa Clara River Watershed, or Calleguas Creek Watershed.

Other Metals

The Basin Plan objectives were exceeded at ME-SCR during Event 3 for total barium¹⁴, cadmium, chromium, and nickel concentrations. This was the only occurrence of elevated levels of these metals at any of the Program's sites for the 2011/12 monitoring year (with the exception of chromium at MO-THO in Event 1). Barium, chromium, and nickel were last above the WQS at ME-SCR in Event 2003/04-1, Event 2004/05-4, and Event 2006/07-3, respectively. Cadmium has been detected above the WQS in 8 of 60 samples since 2001, with the detections spread out over the decade. The associated Major Outfalls do not appear to have caused or contributed to the exceedance of the WQS, since concentrations were consistently below the WQS. Moreover, the total cadmium, chromium and nickel concentrations during Event 3 were similar to those during the other events, and concentrations were not higher at MO-FIL and MO-SPA compared to other outfall stations.

The exact sources of the cadmium, nickel and chromium exceedances at ME-SCR during Event 3 are elusive. However, as these metals are strongly correlated to TSS, they may be at least in part related to the elevated TSS concentrations observed during Event 3. Potential anthropogenic sources of cadmium, chromium and nickel in urbanized watersheds include roof runoff (from roof materials, industrial emissions deposits or atmospheric deposition)^{15,16} and road/highway runoff (fuels and engine oils, exhaust emissions, tire and brake wear).¹⁷

Efforts to reduce metals in urban runoff

Because metals are associated with sediment, the Stormwater Program has a number of control measures and BMPs that address metals in general, and sediment specifically. These control measures include steps to remove sediment from the storm drain system through street sweeping, catch basin cleaning, debris basin maintenance and publicly owned BMPs. A thorough discussion of these programs is provided in Section 7 Public Agency Activities. Preventing sediments containing metals from entering the storm drain system is just as, if not more important than removing them after they enter the storm drain system. Industrial and commercial inspections, construction inspection, and illicit discharge response and elimination, are significant efforts targeted at eliminating the discharge of metals. These are covered respectively in Sections 4 Industrial/Commercial Facilities

¹⁴ Currently, barium is only analyzed at ME-SCR and ME-CC.

Programs, Section 6 Development Construction, and Section 8 Illicit Connections and Illicit Discharges Elimination.

In addition, the construction program element is structured to address sediment from construction sites and includes review of grading plans, requirements for sediment and erosion control BMPs, and field inspections to confirm BMP implementation. More recently the State Water Resources Control Board adopted WDR Order 2009-0009 DWQ, the Construction General Permit, which covers all construction sites with greater than one acre of active land disturbance. The new Construction General Permit incorporates a risk-based approach to address pollutants from construction sites including sediments and associated metals. The Construction General Permit includes rigorous site planning, numeric effluent and action limits, and minimum BMPs as a function of the site risk for discharging sediment. It is expected that this new Construction General Permit will provide further control of sediment from construction sites within Ventura County.

Although the transport of metals is not usually through direct actions of the public, public education of stormwater pollution prevention can provide assistance the efforts of the other programs and future efforts can be tailored to address sources of metals such as promoting household hazardous waste collection events to dispose of mercury containing compact fluorescent light bulbs. Other efforts include the Brake Pad Partnership and [Senate Bill \(SB\) 346](#), legislation that authorizes the phase out of copper from vehicle brake pads discussed above.

Beyond these efforts conducted under our municipal stormwater programs, certain metals (copper, nickel, selenium, and mercury) are being addressed under the various TMDL programs. These constituents have been identified as causing impairment in Calleguas Creek, its tributaries, and Mugu Lagoon. As a result a Metals Work Plan has been developed by the Calleguas Creek TMDL MOA Parties and is currently being implemented¹⁸. This multiple year plan provides the framework to (1) determine whether or not metals impairments still exist in the watershed, (2) develop site-specific objectives for copper and nickel, and (3) if necessary, identify the control measures needed to meet the TMDLs. It is expected that the control measures identified under this effort will inform the efforts to address aluminum and mercury in the Calleguas Creek and Santa Clara River watersheds.

Organics and Pesticides

Two organic compounds were detected at elevated levels during the 2011/12 season, bis(2-ethylhexyl)phthalate at MO-SPA during Event 2 and benzo(a)pyrene at MO-HUE during Event 3. Bis(2-ethylhexyl)phthalate WQS exceedances were not observed in receiving waters which indicates that bis(2-ethylhexyl)phthalate concentrations in urban runoff did not affect beneficial uses in the receiving water. Bis(2-ethylhexyl)phthalate is ubiquitous in plastics and is therefore a common sampling and laboratory contaminant, however, the 2011/12 pre-season equipment blanks analyzed by the Program and the method blank analyzed by the laboratory for this batch were both below the method detection limit for bis (2-ethylhexyl) phthalate. Benzo(a)pyrene is a polycyclic aromatic hydrocarbon (PAH) that is produced by incomplete combustion and is found in fossil fuels. It is not commercially produced or used. PAHs are primarily released to the air and then are deposited onto land/water. Benzo(a)pyrene is also found in coal-tar based pavement sealcoat, however this type of seal coat is not commonly used on the west coast. The benzo(a)pyrene may have been deposited from a residential fire which occurred less than one mile upstream of the monitoring station. The fire was on February 6 and no significant rain fell after the fire until Event 3 on March 17. Outfall from beach fires is also a likely source, and will be investigated if the elevated levels continue to be detected. Each compound was only detected once during the 2011/12 season so they are not

¹⁸ <http://www.calleguascreek.org/ccwmp/4d.asp> November 3, 2011.

considered persistent. Neither compound was detected above the WQS in the receiving waters so they are not considered to cause or contribute to exceedances of WQS.

Pentachlorophenol was the only pesticide detected above WQS criteria, which include a Basin Plan objective of 1 µg/L (wet and dry weather) and a pH-based CTR criterion (dry weather). This occurred at one Major Outfall (MO-MPK, Event 1) during the 2011/12 season. No Pentachlorophenol exceedances were observed in receiving waters. The lack of exceedances for this pollutant at the receiving water station indicates that Pentachlorophenol concentrations in wet weather urban runoff did not affect downstream receiving water beneficial uses with regard to this chlorinated hydrocarbon. In 2011, the Watershed Protection District and the City of Moorpark worked in a joint effort to identify the source of Pentachlorophenol. A special inspection was performed on the SoCal Edison Transfer Station along with special monitoring of the runoff. SoCal Edison responded by increasing BMPs on the site and changing some of their material handling procedures. The Program continued to monitor the area for pentachlorophenol when runoff was present during monitoring events for the 2011/12 season. In addition to the original Edison outfall site (Edison RC pipe at MPK – Lower), the Program monitored a second outfall from the property (Edison RC pipe at MPK – Upper), and a location upstream of MO-MPK and both Edison outfalls (MO-MPK Upstream at RR). The results are shown in Table 9-23. Subsequent sampling events have shown mixed results for the effectiveness of the BMPs. Additional efforts, and follow up and enforcement are the responsibility of the Edison, the City and the Regional Board through their industrial stormwater permit program.

Table 9-23: Pentachlorophenol Results at MO-MPK

Constituent	SiteID	EventID	Sign	Result	Units
Pentachlorophenol	MO-MPK	2010/11-1	=	13	µg/L
Pentachlorophenol	MO-MPK	2010/11-2	=	4.6	µg/L
Pentachlorophenol	Edison RC pipe at MPK - Lower	2010/11-4	=	17	µg/L
Pentachlorophenol	MO-MPK	2010/11-4	=	2.3	µg/L
Pentachlorophenol	MO-MPK	2010/11-5 (Dry)	<	0.04	µg/L

Dry – Not sampled during this event due to insufficient flow at site				

Salts

Concentrations observed above WQS for salts in the three watersheds monitored by the Program were limited to dry weather Event 4 (with the exception of MO-OJA in wet Event 2) that showed elevated levels of chloride and total dissolved solids. This is in accordance with historical data from dry weather events, when flows are comprised of a larger groundwater component. Concentrations above the Basin Plan site-specific objectives of 60 mg/L for chloride and 800 mg/L for total dissolved solids (TDS) were seen at the MO-MEI and MO-OJA Major Outfalls during dry weather Event 4, however the Ventura River at the ME-VR2 receiving water station did not have an exceedance of its corresponding site-specific objectives of 300 mg/L for chloride and 1500 mg/L TDS. Chloride was detected above the site specific objective of 80 mg/L at the MO-FIL Major Outfall during Event 4; however it was not detected above the corresponding site specific objective for the receiving water, 80 mg/L at ME-SCR.

Because urban runoff elevated levels of salts did not co-occur with such elevated levels in receiving waters in the Ventura and Santa Clara River watersheds, the Program concludes that urban runoff monitored during both wet and dry discharge events did not affect receiving water beneficial uses with regard to salts in these watersheds during the 2011/12 season. Levels of TDS above the site specific objective of 850 mg/L were seen at the Major Outfalls MO-SIM and MO-THO during dry Event 4, however ME-CC, the receiving water station, was below the same SSO so the elevated levels at the Major Outfalls did not affect the beneficial use of the receiving water. Levels above the 150 mg/L chloride SSO were also detected during Event 4 at the same two Major Outfalls, MO-SIM and MO-THO, and at the receiving water station, ME-CC, so the urban runoff is likely to have contributed to the exceedance of the Basin Plan Objective for chloride in the receiving water during dry weather Event 4. The area of Simi Valley has a known high ground water problem with natural springs, seeps and artesian conditions in the western part of the County. In addition, there is a Salt TMDL that is evaluating monitoring and implementing solutions throughout the watershed. More information on this is provided below.

The Program is unable to evaluate if concentrations above salts objectives within the watershed are a persistent issue during any given monitoring season because the Program is limited to a single wet season-dry weather monitoring event. Additionally, the other dry weather event, the dry season-dry weather monitoring event, required to be conducted by the Program represents grab sampling (as opposed to composite sampling) and does not include a requirement to evaluate chloride and TDS. The Program can only state that historic monitoring data collected during dry weather sampling events show regular elevated levels of chloride and total dissolved solids objectives in the Calleguas Creek Watershed.

Dry – Not sampled during this event due to insufficient flow at site				
X – Chloride and Total Dissolved Solids				

Boron, chloride, sulfate, and total dissolved solids (“salts”) are currently being addressed in the Calleguas Creek Watershed through the implementation of the Calleguas Creek Salts Total Maximum Daily Load (TMDL), adopted by the Los Angeles Regional Water Quality Control Board in October 2007. The CCW Salts TMDL only applies during dry weather and applies to the receiving water, not at tributary outfalls. During the first three years of the TMDL implementation plan for the watershed, the primary implementation action is water conservation,

which all of the Permittees have done. The ultimate goal of the TMDL is to bring the watershed into “salt balance” where the inputs of salts are equal to or less than the amount of salts exported out of the watershed during dry weather. Water conservation on the part of municipalities reduces the input side of the equation. The salts loading calculation is performed on an annual basis and wet weather exports are not considered in the analysis. Beyond water conservation, the proposed implementation plan does not include many options for MS4 dischargers. Most of the planned actions are construction of groundwater desalters and wastewater treatment plants reverse osmosis as these are considered to be the major source of the salts. Municipal stormwater actions to control salts are limited due to the fact that most salts in runoff come from source water supplies. The primary course of action for municipalities is to reduce outdoor water use, thereby limiting the amount of runoff that may contain high salts from entering urban tributaries and receiving waters. Permittees have also taken steps to the prohibition of discharges from Salt Water pools. Camarillo has conducted outreach to pool service companies and provided articles in their local newsletter to residents alerting them that they cannot discharge salt water pools to the storm drain system. The City of Thousand Oaks and Simi Valley also banned the discharge of salt water pools to the storm drain system. Self regenerating water softeners are a source of salts in the watershed, though not commonly to the storm drain system. Permittees have prohibited their use at commercial and industrial facilities, while education is provided to discourage their use by residents. These are all efforts that should assist with reducing salts in the watershed.

Other Constituents

No other constituents were found to cause or contribute to exceedances of water quality objectives. Dissolved oxygen concentrations below the Basin Plan 5 mg/L objective were measured at the Major Outfalls MO-FIL (Events 3 and 4), MO-HUE (Events 2 and 3), and MO-SIM (Event 1), and at the Ventura River receiving water station, ME-VR2 (Event 2). Possible causes of low dissolved oxygen readings include standing water, oxygen demand by decaying organic matter or algae, and technical issues (e.g. insufficient flow across the meter membrane due to lack of flow or flow obstruction). MO-SIM was sampled early in the hydrograph, when flow may have been insufficient for an accurate reading. The low levels at MO-FIL and MO-HUE are not unexpected as the conditions at both locations create standing water where the water is not agitated or aerated to provide addition of oxygen as would be the case in a flowing storm drain or receiving water. At MO-FIL the monitoring station is at the transition of concrete channel to natural bottom channel and vegetation growth in the natural bottom portion of the outfall impedes the flow resulting in deep, slow moving water at the monitoring location. At MO-HUE the flow from the major outfall must be pumped out to the receiving water, the pumps are intermittent and the flow backs up until they are triggered. Dissolved oxygen measured at the outfall when the pumps are operating is above minimum WQS concentration. No exceedances of the Basin Plan objective for dissolved oxygen were observed at any of the corresponding receiving water stations during the 2011/12 season. Low dissolved oxygen was observed at ME-VR2 but not at either of the upstream outfalls, so the outfalls appear to not cause or contribute to the low dissolved oxygen. The lack of correlation between exceedances for dissolved oxygen at the outfalls and corresponding receiving water stations indicates that dissolved oxygen concentrations in urban runoff did not significantly affect receiving water quality with regard to this parameter. The Program also measured pH levels outside of the Basin Plan’s 6.5 – 8.5 standard unit range during dry weather at the MO-CAM (Event 4), MO-MEI (Event 4), MO-OXN (Event 4), and MO-VEN (Event 4) Major Outfall stations. Elevated pH is commonly observed during dry weather in concrete lined channels. No exceedances of the Basin Plan pH range objective were observed at any of the receiving water stations during the 2011/12 season. The lack of exceedances for pH at the receiving water stations indicates that pH levels in urban runoff did not affect receiving water beneficial uses with regard to this parameter.

Mass Emission Calculations

Mass loadings were estimated for constituents detected at the ME-CC and ME-VR2 Mass Emission stations during the 2011/12 monitoring season. Mass loadings could not be calculated at the ME-SCR station because total flow could not be accurately measured, as described in Section 9.3.1.

Mass loads were calculated by using the average flow total flow volume between first and last aliquot collection in cubic feet divided by the time elapsed between the first and last aliquots in seconds] measured in cubic feet per second, (cfs) estimated over the duration of a monitoring event and the concentrations of detected constituents. For grabs, this is the concentration measured in the grab sample. For composites, this is the concentration measured in the composite bottle, which is a combination of aliquots collected during the event. Event duration was defined as the number of hours elapsed between the collection of the first and the final aliquots by the composite sampler at each site. Storm events monitored during 2011/12 at the ME-CC and ME-VR2 stations lasted from just over 8 hours (Event 2 at ME-VR2) to just over 25 hours (Event 1 at ME-VR2). Based on the average flow rate for a sampling event, loadings were calculated in lbs/event to allow for comparisons between sites as well as between events (see example in Table 9-27). These mass loading estimates are presented in Table 9-28 and Table 9-29.

Table 9-27. Example Mass Loading Calculation

Event 1 at ME-CC
Chloride concentration: 100 mg/L Event duration: 12 hours, 46 minutes = 12.77 hours
Average flow rate: 216.03 cfs $216.03 \times 7.48 \text{ gal/cf} \times 3.785 \text{ L/gal} = 6116.2 \text{ L/sec}$
Load = concentration x volume $6116.2 \text{ L/sec} \times 100 \text{ mg/L} = 611620 \text{ mg/sec}$ $611620 \text{ mg/sec} \times 60 \text{ sec/min} \times 60 \text{ min/hr} \times 12.77 \text{ hr/event} \times 1 \text{ kg}/10^6 \text{ mg} \times 2.2 \text{ lb/kg} = \mathbf{61,858 \text{ lb/event}}$

9.6 MASS EMISSION STATIONS CONCENTRATION TRENDS 2001 - 2012

9.6.1 Methods

Trend analysis was performed for Ventura County's three mass emission station, using data collected between February 2001 (ME-CC and ME-VR/VR2) or November 2001 (ME-SCR) and May 2012. The trend analysis was performed separately for wet and dry weather events, and data for ME-VR and ME-VR2 were pooled to be consistent with the other stations, and to obtain sufficient data for trend analysis.

Concentration trends in time were determined by correlating the variables concentration and sampling date. Non-parametric statistical methods were used, based on the recommendations of Helsel and Hirsh (2002)¹⁹, and therefore tests for normality or data transformations were not required. Trend analyses were performed for all constituents with more than 10% of the data above the limit of detection. Statistical procedures were based on

¹⁹ Helsel, D.R. and R. M. Hirsch, 2002. Statistical Methods in Water Resources. Techniques of Water Resources Investigations, Book 4, chapter A3. U.S. Geological Survey, 522 p.

Helsel and Hirsh (2002)¹⁹ and Helsel (2012)²⁰, and varied based on the occurrence of observations qualified as non-detectable (NDs) and detectable but not quantifiable (DNQ), as summarized in Table 9-30. The statistical procedures used were able to incorporate variable detection and reporting limits. Trends were considered to be statistically significant at $p < 0.05$. Note that the non-parametric statistics do not assume or require linear trends.

Table 9-30. Statistical procedures and software for trend analysis

Constituent concentrations	Statistic	Software
Always above reporting limit	Kendall Tau	Analyze-it for Microsoft Excel
< 90% of observations below detection limit, one detection limit, no DNQs	Kendall Tau	Analyze-it for Microsoft Excel
< 90% of observations below detection limit, multiple detection limits, no DNQs	Kendall Tau	R (package “NADA”)
< 90% of observations below reporting limit, DNQs and NDs occur	Wilcoxon score	R (package “interval”)

Whenever significant trends were found, we also determined if the trends were caused by one of the following explanatory variables: flow (instantaneous for grabs, mean event flow for composites), total suspended solids or antecedent dry period (time since last wet event with at least 0.1” of precipitation). Statistical procedures were based on Helsel and Hirsch (2002)¹⁹ and consisted of (i) determining correlation (using Kendall Tau) between concentration and explanatory variables, (ii) if a significant correlation was observed, a non-parametric Loess trendline of concentration vs. explanatory variable was constructed, (iii) the “corrected” concentration was calculated by subtracting the trendline value from the concentration value, and (iv) the trend analysis was repeated for the “corrected” concentrations versus time. The final “corrected” trends are a better representation of actual trends, and indicate if constituent concentrations *for a given flow*, or *for a given concentration of TSS*, have changed in time. Conversely, trends that are actually caused by patterns of flow, TSS or antecedent dry period would not be identified as significant trends.

Temporal **trends of water quality exceedances** were also determined. The total number of exceedances were summed and divided by the number of events for each monitoring year, for wet and dry events separately, in order to obtain an average number of exceedances per wet and dry event. For dry events, trends were determined between 2001 and 2012. For wet events, data prior to 2004 were not included, because some of the constituents that sometimes cause exceedances were not analyzed at the time. Statistical significance of trends was determined by correlating average annual number of exceedances with time (year) using Kendall Tau. All exceedances were determined by comparing to Basin Plan and CTR numerical water quality criteria, as detailed in Section 9.5.1.

9.6.2 Concentration Trends

Detailed information for all significant trends, including appropriate statistic (Kendall Tau or Wilcoxon score) and statistical significance, is shown in Table 9-31. Note that trends were not corrected for explanatory variables flow, TSS or antecedent dry period in Table 9-31. A summary of increasing and decreasing trends, including revised trends after adjusting for explanatory variables, is provided in Figure 9-9. The most significant findings are discussed below, with some graphs to illustrate trends.

Indicator bacteria

Dry and wet weather *E. coli* concentrations have significantly decreased at ME-CC since 2001. While wet weather concentrations remain high and usually exceed the basin plan objective of 235 MPN/100 ml, dry weather compliance has increased in recent years (Figure 9-10). Decreasing *Enterococcus* trends were observed as well at ME-CC, but these trends disappeared when accounting for flow and TSS concentration patterns. Concentration decreases for **total and fecal coliforms** (dry weather) and *E. coli* (wet weather) were observed at ME-SCR as well.

Figure 9-10. *E. coli* concentrations at ME-CC. Red lines indicate Water Quality Standards.

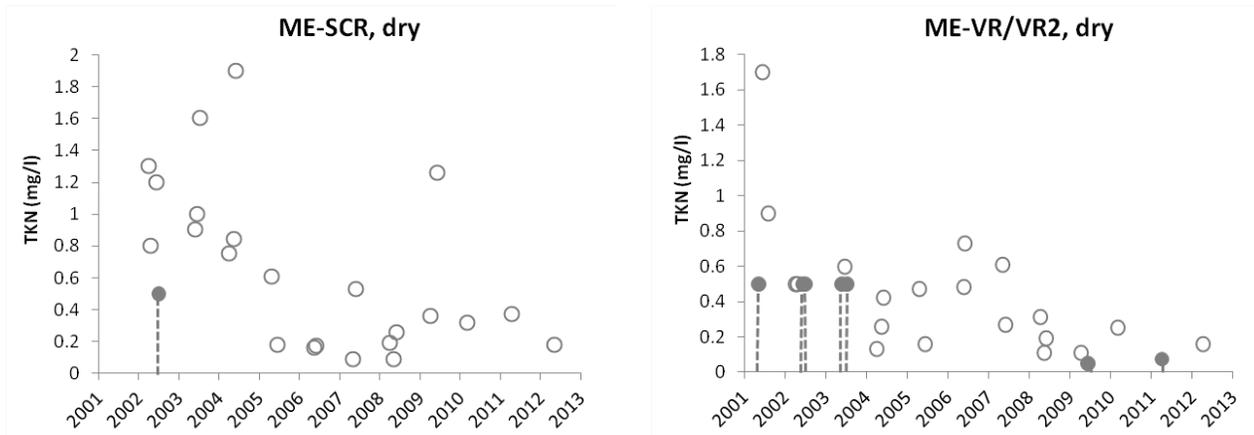

Nutrients

Dry weather **TKN** concentrations decreased at all stations (Figure 9-11), and wet weather TKN concentrations at ME-VR/VR2 only. The initially observed decreasing trend of wet weather TKN concentrations at ME-CC disappeared when accounting for flow patterns.

Dry weather **dissolved phosphorus** concentrations increased at ME-CC, but the increase was small, concentrations remain low (< 3 mg/l) and are not exceeding any water quality objective or TMDL limit.

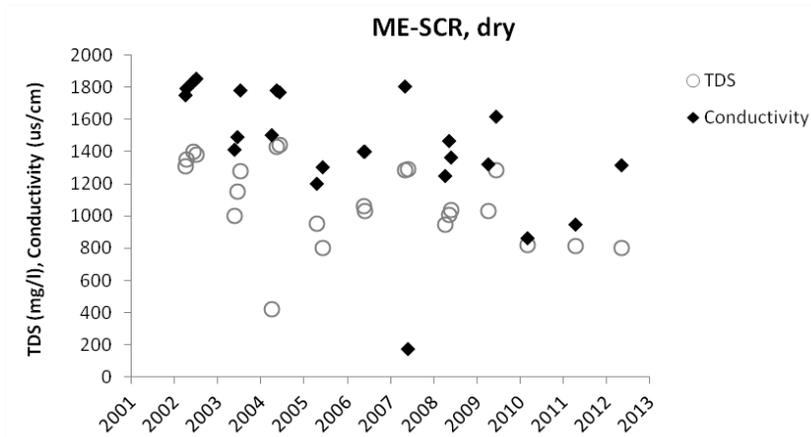

Figure 9-11. Total Kjeldahl Nitrogen (TKN) concentrations at ME-SCR and ME-VR/VR2. Concentrations below the detection limit are indicated by full grey symbols at detection limit value, connected by dotted line to zero.

Salts

Dry weather **TDS, conductivity and hardness** all decreased at ME-SCR (Figure 9-12). In addition, hardness trends at ME-VR/VR2 showed a decrease during for dry weather, but increase for wet weather.

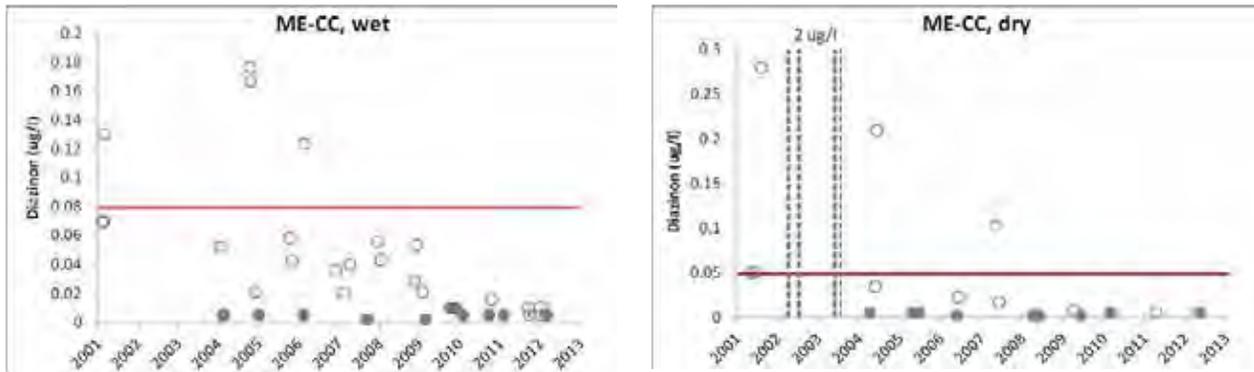

Figure 9-12. Dry weather concentrations of total dissolved solids (TDS) and conductivity at ME-SCR.

Organic compounds

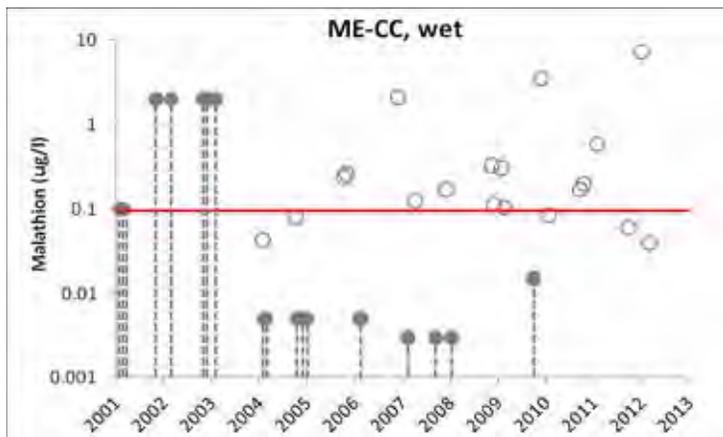

Dry and wet weather concentrations of the pesticide **diazinon** have decreased at ME-CC, to the point that exceedances of the Department of Fish and Game aquatic life criteria have not been observed since 2006 for wet weather and since 2007 for dry weather (Figure 9-13). The U.S. EPA phased out residential uses of diazinon, with a sales ban in the U.S. as of December 31, 2004, which appears to have effectively decreased concentrations at ME-CC. Remaining detections are likely due to the continued use by agriculture and commercial residential uses.

Figure 9-13. Diazinon trends at ME-CC. California Department of Fish and Game recommended criteria are shown by a red line (continuous concentrations for dry weather and maximum concentrations for wet weather). Concentrations below the detection limit are indicated by full grey symbols at detection limit value.

Wet weather concentrations of the pesticide **malathion** have increased at ME-CC, and regularly exceed the U.S. EPA national recommended water quality criterion of 0.1 $\mu\text{g/l}$ (Figure 9-14). Concentrations up to 7.2 $\mu\text{g/l}$ were observed (note the use of log-scale in Figure 9-14), which is at least tenfold higher than maximum concentrations at ME-SCR and ME-VR/VR2. However, current concentrations at ME-CC are 10- to 100-fold lower than concentrations observed in surface waters during the 1994-1995 Mediterranean Fruit Fly Eradication Program.²¹

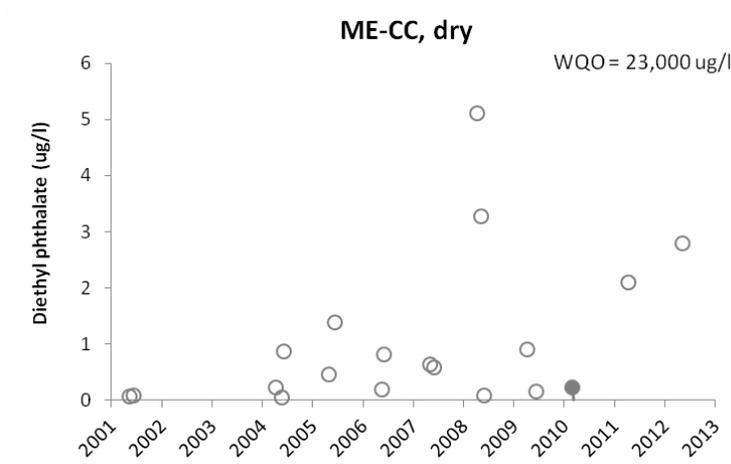

Figure 9-14. Wet weather malathion concentrations at ME-CC. U.S. EPA national recommended water quality criterion is shown by a red line. Concentrations below the detection limit are indicated by full grey symbols at detection limit value, connected by dotted line to zero.

²¹ Newhart, K., 2006. Environmental fate of malathion. California Environmental Protection Agency, Department of Pesticide Regulation.

An increase in dry weather **diethyl phthalate** concentrations was observed at ME-CC (Figure 9-15). As maximum observed concentrations were well below the water quality objective of 23,000 µg/l, the slight concentration increases are of no concern at this point.

Figure 9-15. Diethyl phthalate concentrations at ME-CC for dry weather. Concentrations below the detection limit are indicated by full grey symbols at detection limit value, connected by dotted line to zero.

Metals

Concentrations of many metals have decreased since 2001 at all mass emission stations. Decreasing trends in dry and wet weather dissolved concentrations, and to a lesser degree total concentrations, were commonly observed for **chromium, copper** (Figure 9-16), **selenium and zinc**.

Decreasing dry weather concentrations were also observed for **nickel** at ME-SCR and ME-VR/VR2, and for total **lead** at ME-CC and ME-VR/VR2. **Arsenic** concentrations have increased at ME-CC, but increases are small, and the maximum observed concentration of 4.5 µg/l is still well below the water quality objective of 50 µg/l.

Decreasing wet weather concentrations were observed at ME-CC for total **arsenic, antimony, silver and thallium**; and at ME-VR/VR2 for total and dissolved **cadmium and lead** (Figure 9-17).

Figure 9-16. Wet and dry weather dissolved copper concentrations at ME-SCR and ME-VR/VR2. Concentrations below the detection limit are indicated by full grey symbols at detection limit value.

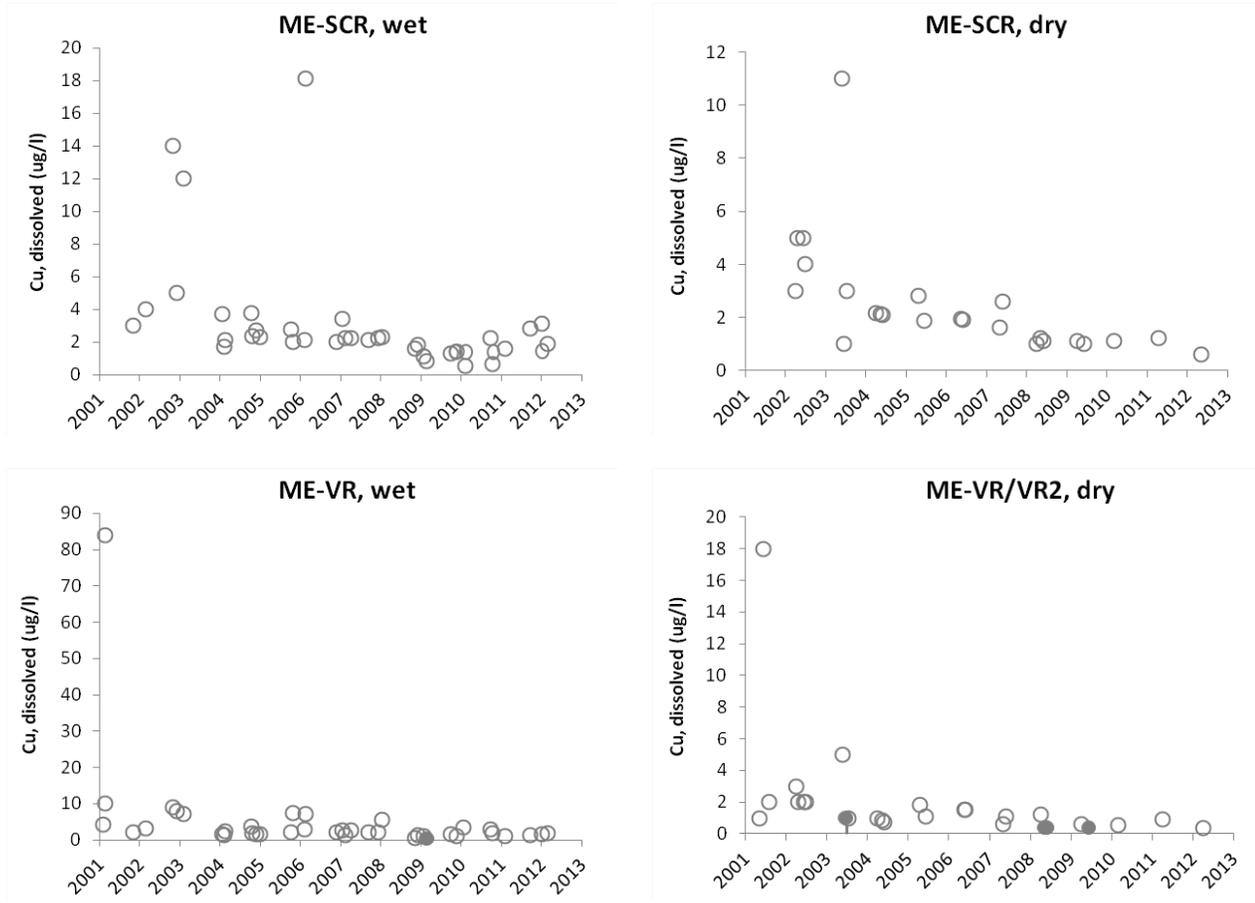

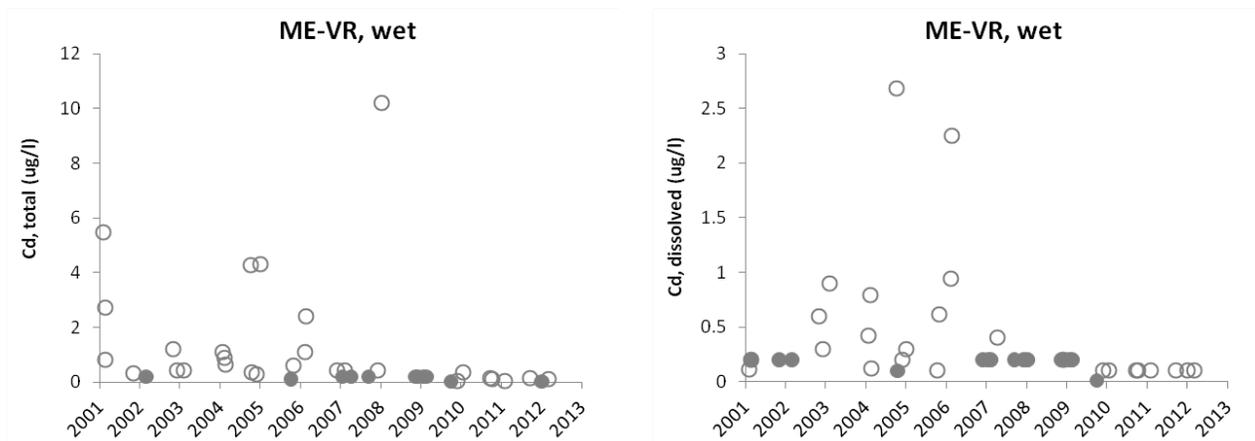

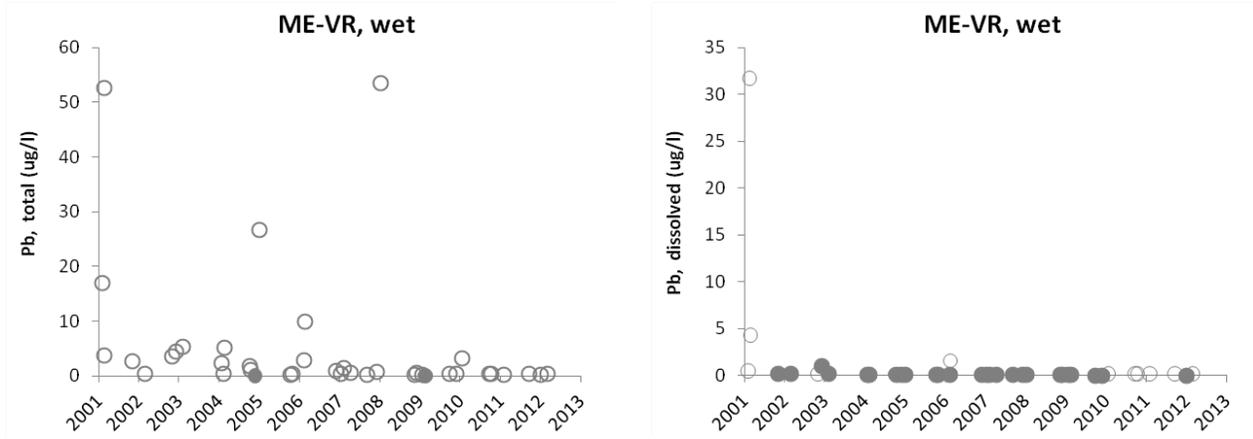

Figure 9-17. Wet weather total and dissolved lead and cadmium concentrations at ME-VR/VR2. Concentrations below the detection limit are indicated by full grey symbols at detection limit value.

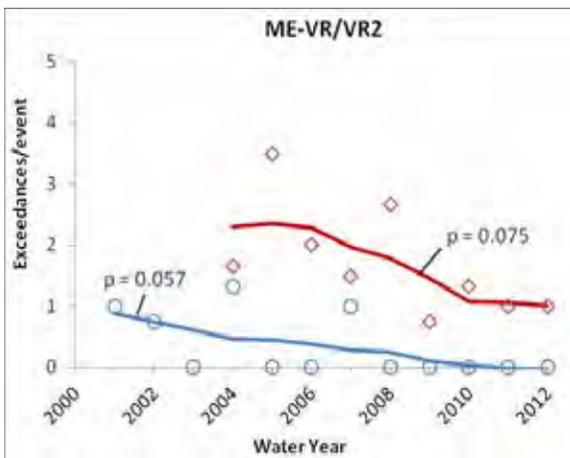

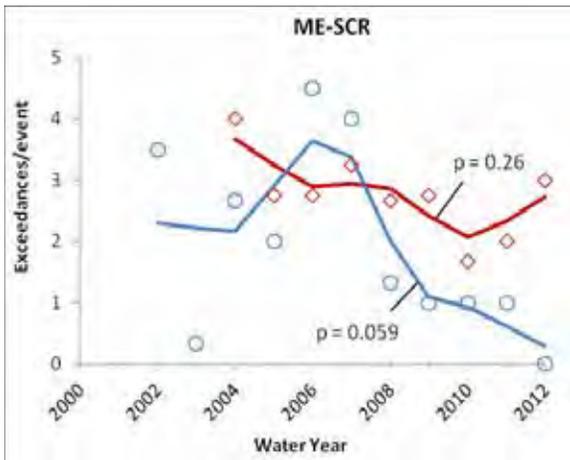

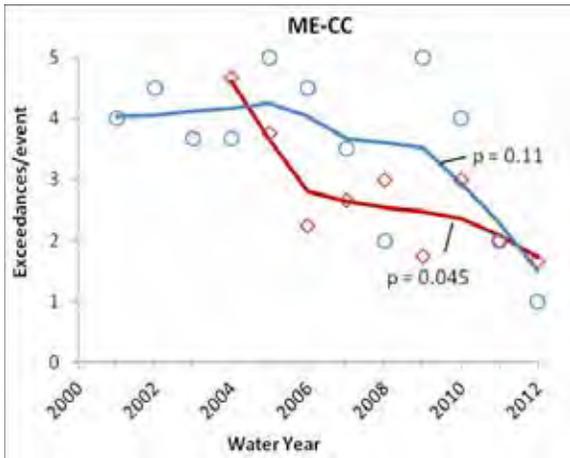

Trends in Water Quality Exceedances

The number of wet weather exceedances has decreased since 2004 at ME-CC and ME-VR/VR2, although the significance is rather low at the latter ($p = 0.075$) (Figure 9-18). A closer inspection of the data revealed that the above average number of exceedances in years 2004 and 2005 were mostly caused by a number of metals (total cadmium, chromium and nickel) for which concentrations correlate with TSS concentrations. Therefore, the decreasing trends are caused, at least partly, by the particularly high metal concentrations during the large storms observed in 2004 and 2005, and the decreasing trend is not expected to continue if high TSS concentrations are observed in the future.

The number of dry weather exceedances appears to have decreased at ME-SCR and ME-VR/VR2 since 2001, with statistical significances just above the threshold of 0.05. This conclusion is supported by the fact that the number of exceedances prior to 2004 is likely low biased, because a number of constituents that have caused dry weather exceedances were not being monitored yet (total aluminum), or had exceptionally high detection limits, resulting in nondetects only (benzo(a)pyrene, chrysene, bis(2-ethylhexyl)phthalate, 4,4'-DDD, 4,4'-DDE and toxaphene). The decrease in exceedances observed at ME-CC is not significant and was caused by the below average number of exceedances during the last two years. Therefore, more dry weather monitoring is needed to confirm if dry weather exceedances at ME-CC are decreasing.

Figure 9-18. Average annual number of exceedances per event for wet (red symbols and lines) and dry (blue symbols and lines) weather sampling. Lines represent Loess curves, obtained by local regression modeling. Kendall Tau statistical significances are included for each set of data.

Conclusions

Most of the 217 constituents currently monitored at the Mass Emission stations by the County have been monitored since 2001. Twenty-six of these 217 constituents, including metals, bacteria, nutrients, salts and one pesticide, have shown decreased concentrations at one or more stations. Only five constituents exhibited increasing trends, each time at only one of the stations, although none of these constituents were causing water quality exceedances based on Basin Plan and CTR numeric water quality criteria. However, malathion concentrations did regularly exceed the U.S. EPA national recommended water quality criterion.

The average number of dry weather exceedances has decreased since 2001 at ME-SCR and ME-VR/VR2. The number of wet event exceedances has decreased since 2004 at ME-CC and ME-VR/VR2, and could be related to the smaller storm sizes and therefore fewer exceedances for metals in recent years.

Table 9-31. Significant trends at mass emission stations. Test statistic is Kendall Tau correlation, unless indicated by asterisk, where test statistic is Wilcoxon score. Decreasing trends are indicated by negative Kendall Tau but positive Wilcoxon score statistics, and vice versa.

9.6.3 Aquatic Toxicity Results

No samples exhibited significant toxicity during the 2011/12 monitoring season, which can be seen in the IC₅₀ column of Table 9-33 and Table 9-34, where no value is < 100% (i.e. the undiluted sample did not kill half the organisms in the test).

The Stormwater Monitoring Program’s NPDES permit specifies that chronic toxicity monitoring must be conducted on all Mass Emission and Major Outfall stations. The permit requires that for the first year a station is online for the permit cycle, chronic toxicity testing is to be conducted using three species during two storm events, the first of the season plus one other. For the remainder of the permit term, toxicity testing is to be conducted for the first storm of the season for each station using the most sensitive species determined during the initial year of sampling. For Mass Emission stations, the tests included three marine and estuarine species: topsmelt, giant kelp, and purple sea urchin. For the Major Outfall stations, the tests included three freshwater species: fathead minnow, water flea, and green algae.

The Permit requires that marine/estuarine species be used for the mass emission stations and for sites that discharge into marine receiving waters. Freshwater species must be used for sites that discharge into freshwater receiving waters. This means that marine species are required to be used in freshwaters, such as at the three mass emission stations, and freshwater species are required to be used at the major outfalls, including MO-HUE which is influenced by the Pacific Ocean via J Street Drain. Although flow from all sampling sites is ultimately discharged to the ocean, Mass Emission samples are freshwater with a very low salt concentration. The use of marine species for the Mass Emission sites requires the sample to be greatly manipulated by adding a large quantity of salt. Salt addition results in oxygen uptake and requires the sample to be vigorously aerated. The results from marine organisms for freshwater toxicity tests are less applicable to the existing conditions in the receiving water than freshwater organisms..

The most sensitive species was determined for seven stations (ME-CC, ME-SCR, ME-VR2, MO-CAM, MO-MEI, MO-OJA, and MO-VEN) during the 2009/10 monitoring year. The other seven stations (MO-FIL, MO-HUE, MO-MPK, MO-OXN, MO-SIM, MO-SPA, and MO-THO) were brought online for the 2010/11 monitoring year and the most sensitive species were determined from the results from that year. The most sensitive species for each site are shown in Table 9-32, and will be used for toxicity analysis during the first rainfall event of future years, as required by the NPDES permit.

Table 9-32: Most Sensitive Species Selected for Annual Toxicity Testing

Site	Most Sensitive Species
ME-CC	Topsmelt*
ME-SCR	Purple sea urchin
ME-VR2	Topsmelt*
MO-CAM	Fathead minnow
MO-OJA	Fathead minnow
MO-MEI	Fathead minnow
MO-VEN	Water flea
MO-FIL	Water flea
MO-HUE	Water flea
MO-MPK	Green alga
MO-OXN	Fathead minnow
MO-SIM	Water flea
MO-SPA	Fathead minnow
MO-THO	Water flea

Toxicity sampling was conducted at all fourteen stations during Event 1 (October 5, 2011) of the 2011/12 monitoring year, using the most sensitive species determined for each site. The results are summarized in Table 9-33 and Table 9-34.

According to the NPDES permit, a Toxicity Identification Evaluation (TIE) must be performed on samples exhibiting significant toxicity, defined in the permit as at least 50% mortality (IC₅₀ < 100%). For tests with only one endpoint where survival is not measured, such as the purple sea urchin or green alga, a TIE is triggered when the primary endpoint of the test has greater than 50% effect. For the purple sea urchin, this equates to a fertilization rate of less than 50%. For the green alga, it equates to growth that is less than half of that of the control sample.

A closer inspection of the tables reveals that there were two stations (ME-SCR using the purple sea urchin and MO-SPA using the fathead minnow) in which the TUC exceeded 1.00 and the NOEC was below 100%. TIEs were not run on these samples because the IC₅₀ for these sites was always greater than 100%, meaning the sample would have to be concentrated to kill 50% of the organisms in the sample. More detailed results are available in Appendix I in Attachment E.

9.7 DRY-SEASON, DRY-WEATHER ANALYTICAL MONITORING

As described in the NPDES permit, dry weather monitoring is required once during each dry season (May 1 – September 30) at sites selected to be representative of runoff from each of the Permittees jurisdictions (each city and the county unincorporated area) in Ventura County. For most jurisdictions, monitoring occurred at the associated Major Outfall monitoring station; however, as anticipated, inadequate flow was encountered at three of the Major Outfall stations prompting the relocation of these sampling sites. Receiving water monitoring is not part of this Permit requirement.

The eight jurisdictions with sampleable dry-season, dry-weather Major Outfall locations were: Camarillo, Fillmore, Moorpark, Ojai, Oxnard, Simi Valley, Thousand Oaks, and Ventura. For the remaining three jurisdictions, the list of alternate sites was used to select a location with adequate flow. For Santa Paula, the site was moved from the 11th Street Drain to Fagan Canyon, for Port Hueneme, the site was moved upstream to Bubbling Springs Park, and the County Unincorporated site was moved from Happy Valley Drain in Meiners Oaks to Medea Creek in Oak Park.

Sampling took place on two days. Fillmore-1 (MO-FIL), Ojai-1 (MO-OJA), Oxnard-1 (MO-OXN), Port Hueneme-3 (Bubbling Springs Park), Santa Paula-2 (Fagan Canyon), and Ventura-1 (MO-VEN) were sampled on August 15, 2012. Camarillo-1 (MO-CAM), Moorpark-1 (MO-MPK), Simi Valley-1 (MO-SIM), and Thousand Oaks-1 (MO-THO), and Unincorporated-2 (Medea Creek in Oak Park) were sampled on August 16, 2012. There was at least 72 hours of dry weather preceding each sampling event.

As required by the NPDES permit, grab samples were collected and analyzed for total coliform, *E. coli*, total hardness, total organic carbon, and three dissolved metals: copper, lead, and zinc. Field observations and measurements were also taken. The results are presented in Appendix J and laboratory QA/QC is included in Appendix F in Attachment E. Constituents outside of water quality standards are in Table 9-35.

Uncommonly high elevated levels were seen for copper at Camarillo-1. In an effort to narrow down the potential source of the copper and bacteria follow-up samples were collected on October 17, 2012, (prior to the first rainfall of the wet season) at Camarillo-1 and three sites upstream to look for the source of the elevated levels of copper and *E. coli* detected during the DRY-2012 event. Since there are multiple connections to Camarillo Hills Drain upstream of the Camarillo-1 site and it is unknown which were flowing at time of sample collection during DRY-2012, follow-up results cannot be directly related to previously collected samples but any high results may indicate the geographic area of possible sources and create an opportunity to pinpoint and eliminate them. Results of the follow up sampling were not available at the time of this writing, and will be detailed in the next annual report.

9.8 BIOASSESSMENT MONITORING

As instructed in the current NPDES permit, the Stormwater Monitoring Program participated in the Southern California Regional Bioassessment program. This program was run by the Southern California

Coastal Water Research Project (SCCWRP) and included participation from multiple agencies and organizations. The Stormwater Monitoring Program was responsible for sampling 15 qualified probabilistic sites throughout Ventura County, divided among each of the three major watersheds (six in the Ventura River Watershed, six in the Calleguas Creek Watershed, and three in the Santa Clara River Watershed). Probabilistic site locations were randomly generated by SCCWRP and evaluated by District staff to ensure each site met the requirements of the program (e.g. accessible, perennial, permission granted etc.). Sites that did not meet the requirements of the program were rejected and evaluation of sites continued until the requisite number of sites were qualified. The Stormwater Monitoring Program was also responsible for sampling three trend sites, one in each of the three watersheds. Trend sites were selected for their location and are to be monitored each year for the duration of the study.

With help from Aquatic Bioassay & Consulting Laboratories, Inc. (ABC), sampling was conducted June 4, 2012, through July 19, 2012. The reconnaissance, chemistry, California Rapid Assessment Method (CRAM), physical habitat (P-HAB), and toxicity data was submitted electronically to SCCWRP by the appropriate due date (September 30, 2012 for reconnaissance; October 31, 2012 for chemistry, CRAM, P-HAB, and toxicity). Taxonomic identification of invertebrates and algae is being undertaken by outside laboratories is not under the jurisdiction of the Stormwater Monitoring Program. This data is currently due to SCCWRP by February 28, 2013.

A technical and non-technical report summarizing the first year's data (2009) was released in 2011 and is available at SCCWRP's website www.sccwrp.org. SCCWRP and the SMC do not currently plan to produce interim reports for the second through fourth years (2010 - 2012) of the study. Links to all reports will be included in future Annual Water Quality Monitoring Reports, as they become available.

9.9 BEACH WATER QUALITY MONITORING

The Permit requires the Program to fund beach water quality monitoring in accordance with procedures and locations used in AB411 monitoring at ten sites if funding from state and federal sources is not available. Those funds were available during the reporting period so the County of Ventura Environmental Health Department conducted ocean water quality monitoring at 40 sites along the Ventura County coast, including the ten sites listed in the Permit. The Program was not involved in the monitoring, however, the results of that monitoring is summarized in Table 9-36 below. Compliance with limits set by the State of California for each parameter was achieved in over 98.9% of samples. *Heal the Bay's 2011-2012 Annual Beach Report Card* gave Ventura County Beaches an A grade for both wet and dry weather. Grades are given on an A to F scale, with higher grades representing lower risk of illness for beachgoers.

Table 9-36 Beach Water Quality Monitoring Results July 1, 2011 through June 30, 2012

	Total Coliform (TC)	Fecal Coliform (FC)	Enterococcus (Entero)	FC:TC
Number of Samples	1,581	1,581	1,580	1,581

9.10 PYRETHROID INSECTICIDES STUDY

Summary

Pyrethroid insecticide monitoring of sediments is required by Monitoring Program No. CI 7388, as part of the Ventura County Municipal Separate Storm Sewer System National Pollutant Discharge Elimination System Permit, Order No. R4-2010-0108 (Permit). The Permit specifies that the Principal Permittee shall perform a pyrethroid insecticides study to accomplish the following objectives:

- i. Establish baseline data for major watersheds;
- ii. Evaluate whether pyrethroid insecticide concentrations are at or approaching levels known to be toxic to sediment-dwelling aquatic organisms;
- iii. Determine if pyrethroids discovered are from urban sources; and
- iv. Assess any trends over the permit term.

No significant levels of pyrethroids or sediment toxicity were detected at any of the monitored sites.

In April 2012 the Ventura County Watershed Protection District (District), as the Principal Permittee, conducted sediment monitoring for the Pyrethroid Insecticides Study (Study) at two locations in both the Ventura River and Santa Clara River watersheds. In addition, Pyrethroid analysis of sediments in the Calleguas Creek Watershed (CCW) is conducted annually in August as part of the CCW Toxicity Total Maximum Daily Load (TMDL) monitoring program. Data from the TMDL was used to meet the requirements for that watershed, as allowed by the Permit.

Four pyrethroids were detected in the Study samples and varied depending on site. The four detected pyrethroids were bifenthrin (three sites), pendimethalin (two sites), permethrin (one site) and dichloran (one site). Toxicity units were calculated based on the concentration of the pyrethroid (normalized for total organic carbon) and the known *Hyaella azteca* LC50, if available. All calculated toxicity units were less than one indicating the samples were non-toxic. This is also supported by the lack of toxicity seen in the analysis of the sediment samples.

Three years of data (2008-2010) are currently available for the TMDL site (03_UNIV) that was selected as the most representative of urban land use in the Calleguas Creek Watershed. Data for 2011 and 2012 will become available after the TMDL annual reports are submitted in February 2013 and 2014, respectively. Pyrethroids were not detected in the three years of samples, which prevents the calculation of toxicity units; however using the MDL in the calculation provided an estimated upper limit of toxicity units for the sample. Eight of the eighteen calculated data points were above one, which indicates that if pyrethroids were present, but just below detectable levels, there could be a contribution to sediment toxicity. Toxicity was not observed in the corresponding sediment samples, which suggests that concentrations of pyrethroids in the samples, if present, are well below the MDL.

Due to the absence of significant toxicity in the samples, there are no recommendations to mitigate urban contributions of pyrethroids in the three sampled watersheds at this time other than to continue the Ventura Countywide Stormwater Management Program's current pesticide use education and outreach efforts. The Program plans to add Calleguas Creek Watershed sample sites to the Study for 2015 to avoid issues with different detection levels and sampling strategies for the next reporting cycle.

Methods

The Permit allows the Pyrethroid Insecticides Study (Study) requirement to be satisfied by another tributary monitoring program within the watershed if pyrethroid concentrations and sediment toxicity are being assessed. Monitoring in the Calleguas Creek watershed for the Calleguas Creek Toxicity Total Maximum Daily Load (TMDL) meets the study requirements, so this data was used for the Calleguas Creek watershed component. Monitoring for this project has been conducted annually in August since 2008. The data will be released once the TMDL annual report has been submitted, so data collected in 2011 will become available in February 2013 and data collected in 2012 will become available in February 2014. For this reason, this report summarizes the 2008-2010 data. The 2011 and 2012 data will be included in the next report. The Ventura River and Santa Clara River watersheds do not have monitoring programs that meet the Study requirements, so a Pyrethroid Insecticides Study Quality Assurance Project Plan (QAPP) was developed for monitoring these two watersheds. The Study was designed to be similar to the TMDL monitoring project in regard to sample collection method and analyte list. The two projects differ in placement of sites, sampling frequency, and time of year for analysis.

In-stream sediment samples for chemical analysis and toxicity testing were collected using stainless steel scoops according to methods developed by the USGS and outlined in *Guidelines for Collecting and Processing Samples of Stream Bed Sediment for Analysis of Trace Elements and Organic Contaminants for the National Water Quality Assessment Program (1994)*. When possible, sediment sampling stations encompassed a section of the reach approximately 100 meters in length upstream from water-column sampling stations but this varied depending on site conditions. Five to ten wadeable depositional zones (low energy areas where fine-grained particles can accumulate) within the reach were targeted to obtain a sample representative of the site.

All sediment samples were analyzed for total organic carbon (TOC) by EPA 9060 and pyrethroids, GC/MS NCI-SIM for the Study and EPA 8270C (SIM) for the TMDL. Two of five TMDL sites and all Study sites were analyzed for toxicity to 7 to 10 day old *Hyalella azteca*, as described in *Aquatic Toxicity Due to Residential use of Pyrethroid Insecticides*²². Water quality field measurements were taken with hand-held probes.

The stainless steel trowels used by the Study were cleaned prior to sample collection with Citranox laboratory detergent and tap water, rinsed with distilled water, and air dried. They were then sealed individually in Ziploc bags until arrival at the site. An equipment blank was collected by the laboratory from one clean, unused stainless steel trowel by rinsing with one liter of laboratory grade de-ionized water and analyzing the rinsate for TOC by SM 5310C and pyrethroids by GC/MS NCI-SIM. The re-analysis of the equipment blank required a second rinse of the trowel (to collect the required sample volume) with one liter of laboratory grade de-ionized water and analysis by GC/MS NCI-SIM.

The Permit specifies that monitoring is to be conducted every three years, after sediment has settled within the water body and safe access can be assured. For the Study, this translated to April 3, 2012, three days after a small storm (<0.3" precipitation) and 9 days after a larger storm (1.5" precipitation). Sampling for the TMDL is conducted annually in August.

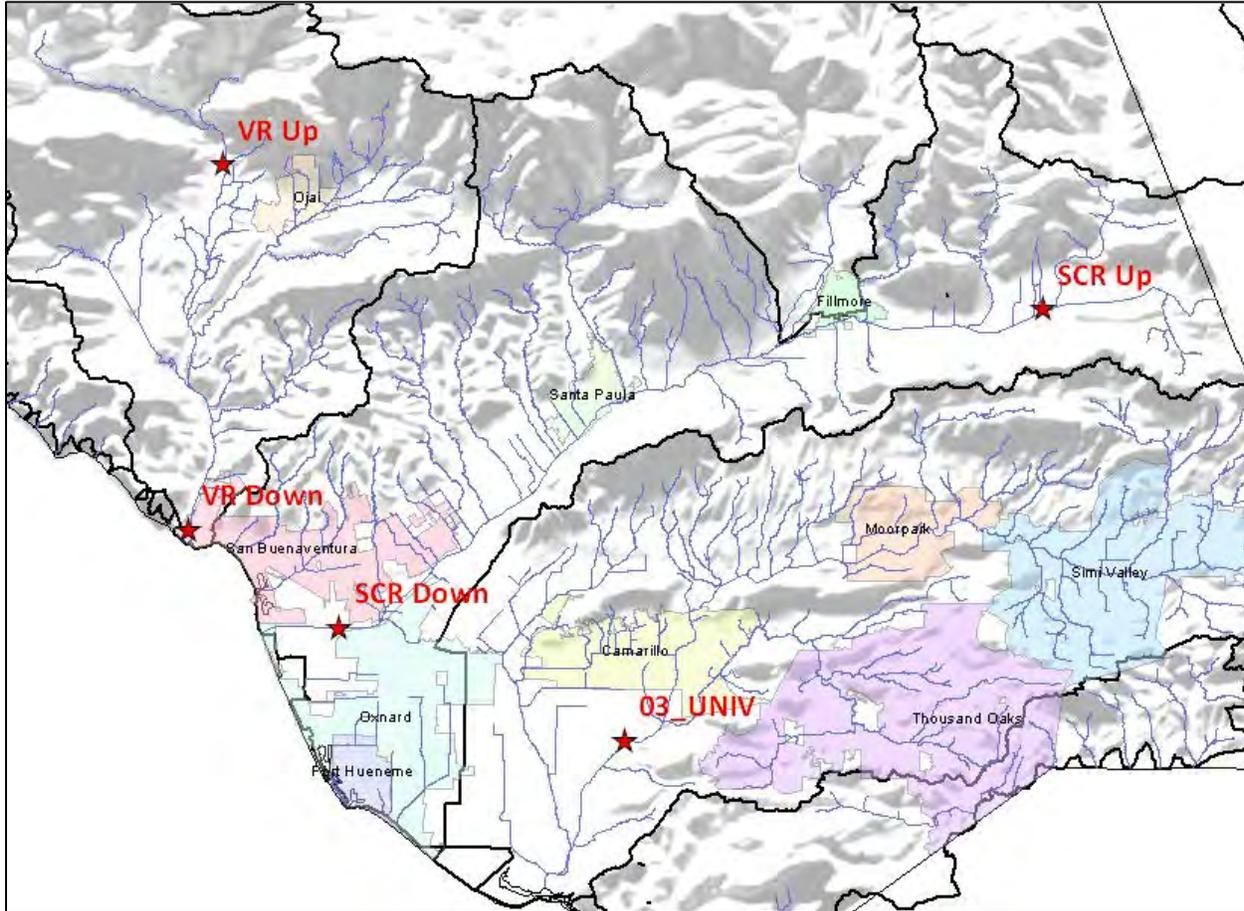

²² *Aquatic Toxicity Due to Residential Use of Pyrethroid Insecticides*; Weston, D., Holmes, R., You, J., Lydy, M.J (2005). Environ. Sci. Technol.; (Article); 2005; 39(24); 9780 pp.

Ventura and Santa Clara River Watersheds

For the Study, an upstream and a downstream site were selected on the main stems in the Ventura and Santa Clara River watersheds (Figure 9-19). The upstream site was located high in the watershed to reduce the influence of urban sources and the downstream site was located low in the watershed to include urban contributions. For the Ventura River, the upstream site is above the Casitas Municipal Water District's diversion structure near the north end of Rice Road in Meiners Oaks (VR Up, Figure 9-20). The downstream site is near the Main Street Bridge in Ventura (VR Down, Figure 9-21). For the Santa Clara River, the upstream site is east of Torrey Road in Fillmore²³ (SCR Up, Figure 9-22) and the downstream site is near the Victoria Avenue Bridge in Ventura (SCR Down, Figure 9-23). Factors such as safety, ease of entry, upstream land use, hydrology, and long term accessibility including landowner permission were considered in site selection.

²³ Note that urban and agricultural areas are present upstream of Fillmore beyond the Ventura County boundary.

Figure 9-19 Pyrethroid Sampling Locations 2012

As described in the Ventura County MS4 Pyrethroid Insecticides Monitoring Quality Assurance Project Plan (QAPP), the top layer (~1 cm) of recently deposited sediment was collected with a pre-cleaned stainless steel scoop as specified in the permit. The quantity of sediment required for the tests precluded sampling directly into glass jars, so the sediment was deposited in a 24" by 36" 2mm polyethylene bag per site. The bag was closed and the sediment was manually homogenized onsite by squeezing and rotating the bag. Homogenized sediment was placed in two 8 oz wide-mouth glass jars and placed on ice for TOC and pyrethroid analysis. The jars were placed in the freezer at the end of the sampling day so that they could be frozen for pickup by the chemistry lab courier the following day. The remaining sediment (~ 3 liters) was double-bagged and put on ice for (same day) delivery to the toxicity lab.

Figure 9-20. VR Up

Figure 9-21. VR Down

Figure 9-22. SCR Up

Figure 9-23. SCR Down

Calleguas Creek Watershed

The Calleguas Creek Watershed is unusual because most of its developed areas are in the upper portions of the watershed with the lower portions heavily influenced by agriculture. The monitoring plan for the TMDL selected sites by subwatershed and appears to have focused on agricultural areas. The TMDL site that best represents the urban contribution of the watershed is 03_UNIV, which is on Calleguas Creek at University Drive, downstream of the Cities of Thousand Oaks, Moorpark, Simi Valley, and parts of Camarillo (Figure 9-19). This site has been monitored for total organic carbon, pyrethroids in sediment, and toxicity to *Hyalella azteca* since August 2008.

As described in the Calleguas Creek Watershed Management Plan Quality Assurance Project Plan Monitoring and Reporting Program Plan for the Nitrogen, OC and PCBs, Toxicity, and Metals and Selenium Total Maximum Daily Loads (TMDL QAPP), sediment samples were collected from the top two to three centimeters (cm) of sediment using pre-cleaned stainless steel trowels. Collecting a thicker

layer of sediments is a common approach to conducting sediment sampling for the purpose of sediment toxicity testing and is the approach used in sediment toxicity studies conducted by the Southern California Coastal Water Research Project (SCCWRP) Bight Program and the State Water Resources Control Board Bay Protection and Toxic Cleanup Program (BPTCP). The sediment samples were collected directly into a clean polyethylene bag and mixed. Subsamples from the bag were placed into glass jars for pyrethroid and TOC analysis and the remaining sediment was kept in the bag for toxicity analysis. All samples were stored at 4°C until arrival at the contract laboratory.

Results

Study Equipment Blank

The initial analysis of the equipment blank detected a small amount of TOC and detectable amounts of the pyrethroids bifenthrin, cypermethrin, and pendimethalin (Table 9-37). In order to have sufficient volume to re-test the equipment blank, the laboratory rinsed the trowel a second time with one liter of deionized water and the rinsate was analyzed for pyrethroids. Pyrethroids were not detected in the second sample (please refer to discussion section, below).

Santa Clara and Ventura Rivers

Toxicity (survival) was not observed in any of the four samples collected by the Study (SCR Up, SCR Down, VR Up, and VR Down). The *H. azteca* percent survival ranged from 83.75% at VR Up to 98.75% at SCR Up. TOC amounts were lower in the Santa Clara River (5.4 g/kg SCR Up and 11 g/kg SCR Down) than in the Ventura River (22 g/kg VR Up and 26 g/kg VR Down), which may be due to the sandy substrate of the Santa Clara River. TOC was higher in the downstream site for each watershed. Detectable amounts of bifenthrin, dichloran, pendimethalin, and permethrin were seen at least one of the four sites (Table 9-38). Each site had a detectable amount of at least one pyrethroid (permethrin, dichloran, bifenthrin, and/or pendimethalin).

Calleguas Creek

Toxicity to *Hyalella azteca* (survival) was not observed in the three samples collected at 03_UNIV between 2008 and 2010. The percent survival ranged from 96.3% in 2008 to 77.5% in 2010. TOC amounts were between 0.2 g/kg (2008) and 3.8 g/kg (2009). Pyrethroids were not detected in any of the three samples. The TMDL results for 03_UNIV are shown in Table 9-39.

Discussion of Results

The source of the detected amounts of the pyrethroids bifenthrin, cypermethrin, and pendimethalin in the original equipment blank is uncertain. Since the laboratory only collected sufficient volume of rinsate to analyze for pyrethroids once, the re-analysis required additional volume which was collected by rinsing the trowel a second time with one liter of laboratory grade deionized water. No pyrethroids were detected in the second analysis. Because the original sample was not available for re-analysis, the source of the contamination cannot be determined. The original rinse may have removed the pyrethroid contaminants from the trowel, they may have dissipated in the time between rinses, or the equipment blank may have been contaminated during rinsate collection and/or analysis at the laboratory.

Regardless of whether the pyrethroid contamination occurred at the laboratory or was present on the trowel, the amount of contamination is insignificant in comparison to the amounts detected in the environmental samples. The total mass of each pyrethroid detected in the one liter of equipment blank rinsate is equal to the concentration, since the total rinsate volume was one liter. This amount is at least two orders of magnitude below the concentrations detected in the environmental samples. The amounts of pyrethroids detected in the environmental samples could be considered to be upper limits for those constituents that were also detected in the equipment blank. The laboratory determined that the initial detection of pyrethroids in the equipment blank may have been due to laboratory contamination, however since the re-analysis involved collecting a separate volume of rinsate, this cannot be confirmed.

The amount of TOC measured in the equipment blank was at least four orders of magnitude below the environmental samples and so can be considered insignificant.

Toxicity levels vary between pyrethroids. Toxicity units (TU) can be used to compare the relative toxicity of different samples and pyrethroids. This is done by normalizing the sediment pyrethroid concentrations to TOC concentration to account for hydrophobicity and then dividing by the *Hyalella azteca* ten day median lethal concentration (LC50) for each detected pyrethroid, if available. The overall pyrethroid toxicity of a particular sample can be calculated by summing the calculated pyrethroid TU for that sample.

The calculated toxicity units from the Study samples were all less than one (Table 9-40) and so the samples can be considered non-toxic. Even though an LC50 for dichloran or pendimethalin is unavailable, the lack of toxicity in the environmental sample infers a calculated TU of less than one for these analytes. The calculated TUs were inversely correlated with the observed toxicity, possibly due to the presence of unanalyzed constituents in the sample.

Pyrethroids were not detected in the samples collected in 2008, 2009, and 2010 from the Calleguas Creek watershed site (03_UNIV). The Permit requested that pyrethroid detection limits be as close to 1 ng/g (dry weight) as reasonably achievable. Since the pyrethroid detection limits for the TMDL were above this amount and all the results were non-detects, the MDL was used in place of a measured result in order to calculate the maximum possible TU for each analyte in each sample, for pyrethroids with available LC50s. Pyrethroid concentrations at the MDL were above one for eight of the eighteen calculable data points (Table 9-40). Toxicity was not observed in any of the three 03_UNIV samples, which suggests that concentrations of pyrethroids in the samples, if present, would be at concentrations well below the MDL for each analyte. Pyrethroids were detected in sediment samples from some of the other TMDL sites in the Calleguas Creek watershed; however they were at sites where agriculture is the predominant land use.

Pesticide Reduction Efforts

Integrated Pest Management Programs

A model integrated pest management (IPM) program was drafted through the Public Agencies Activities Subcommittee and used as a template by the Permittees to

Spanish Language Pesticide Outreach

develop their own plans by November 2009. This standardized protocol is posted on Program's website at www.vcstormwater.org/documents/subcommittees_publicagency/publications/VC_Pesticide_Protocol_10-09.pdf.

The prevention of pesticides from harming non-target organisms is the primary goal of the Permittees IPM program. The intent is to focus on preventing pesticides, fertilizers, and herbicides from entering the storm drain system and discharging to receiving waters. This protocol is applicable to 1) the outdoor use of pesticides, herbicides, and fertilizers; 2) the use of pesticides and fertilizers where the materials may come into contact with precipitation; 3) the use of pesticides, herbicides, and fertilizers where these materials may come into contact with runoff (natural or induces); and 4) the use of pesticides, herbicides, or fertilizers anywhere where they may be directly or indirectly discharged to a storm drainage system.

An effective IPM program includes the following elements:

- Pesticides are used only if monitoring indicates they are needed according to established guidelines.
- Treatment is made with the goal of removing only the target organism.
- Pest controls are selected and applied in a manner that minimizes risks to human health, beneficial, nontarget organisms, and the environment.
- Its use of pesticides, including Organophosphates and Pyrethroids do not threaten water quality.
- Partner with other agencies and organizations to encourage the use of IPM.
- Adopt and verifiably implement policies, procedures, and/or ordinances requiring the minimization of pesticide use and encouraging the use of IPM techniques (including beneficial insects) in the Permittees' overall operations and on municipal property.
- Policies, procedures, and ordinances shall include commitments and timelines to reduce the use of pesticides that cause impairment of surface waters by implementing the following procedures:
 - Quantify pesticide use by its staff and hired contractors.
 - Prepare and annually update an inventory of pesticides used by all internal departments, divisions, and other operational units.
 - Demonstrate reductions in pesticide use.

The protocol is applicable to any Permittee staff and contracted services that apply pesticides, fertilizers, or herbicides. Such staff commonly include, park, public works, purchasing, building/grounds maintenance, hazardous materials, and pesticide application staff. It is not applicable to the indoor use of pesticides, herbicides or fertilizers, but is applicable to the consequential outdoor handling, mixing, transport, or disposal of materials related to indoor use. This protocol also does not apply when another NPDES permit and/or abatement orders are in effect at the selected site. Furthermore, this protocol is not intended to replace federal or state requirements or provide complete directions for applying, handling, transporting, mixing, or storing pesticides, fertilizers, or herbicides.

Proper Pesticide Use Newspaper Advertisement

Public Outreach and Education on Pesticide Use

Timed to coincide with the spring planting season, the Program’s outreach effort (Community for a Clean Watershed) ran a five-week pesticide campaign in 2010 utilizing television and radio campaign elements from past year’s creative arsenal. The animated “More, Better” television commercial graphically demonstrated how using too much pesticide runs into the storm drains, eventually making it into the Watershed, adversely affecting plants and animals. The radio spot was a humorous adaptation of the television ad, featuring the two animated characters as they defend their house against garden pests and inadvertently poison the watershed. An animated web banner corresponded with both broadcast media while the transit shelters took a more direct approach showing a snail and telling residents “Don’t kill an ocean just to keep pests out of your garden.”

Retail Partnership Brochures: Nurseries and Gardeners,

Watershed Protection Tip pamphlets aimed at residents were created to encourage best practices in their homes. These brochures were distributed to targeted retail stores to reach the population that is likely involved in the activities. The colorful pamphlet defines the Watershed, explains the storm drain system, how polluted water is damaging and gives both overall and topic-specific tips for how to keep the Watershed clean. In this case the one aimed at gardeners talks about plant selection, irrigation, fertilizer and pesticide practices, integrated pest management and proper yard maintenance.

Recommendations

Due to the absence of significant toxicity in the samples, there are no recommendations to mitigate urban contributions of pyrethroids in the three sampled watersheds at this time other than to continue the Ventura Countywide Stormwater Management Program's current pesticide use and public education and outreach efforts. The Program plans to include Calleguas Creek Watershed sample sites in the Study for 2015 to avoid issues with different detection levels and sampling strategies for the next reporting cycle. Additionally, the Program will review its procedures and methods to ensure the highest quality data is generated from the 2015 Pyrethroid Study.

The Watershed Should Only Shed Water
The storm drain system is a vast network.

Watershed Protection Tips for Gardeners

What Is Our Watershed?
Our watershed is the total land area, including your yard, from which stormwater drains into streams, rivers or other bodies of water. In Ventura County our primary watersheds drain into the Ventura and Santa Clara Rivers, Malibu and Calleguas Creeks and the marinas and estuaries that flow into the Pacific Ocean.

Clean Gardening Practices

Plant Selection
Select pest-resistant and drought-tolerant native plants for your garden to reduce the need for pesticides. Fertilizers and water. Create landscape areas that are safe for children and pets. Collect and filter any potentially polluted runoff from paved surfaces. Go to www.waterworks.com for a California-Friendly Gardening Guide.

Irrigation
Save water and money by substituting your sprinkler system. Irrigate after dusk or early in the morning when less water is lost to wind and evaporation. Even during the hot summer months, there is no need to water every day. Restrictly fix leaks and damaged sprinkler heads to minimize runoff that carries pollutants into the storm drain system.

Fertilizers & Pesticides
Overuse of any pesticide or fertilizer is a key contributor to stormwater pollution. Apply only as needed and as directed on the label, and always wear under cover, out of the rain. Never use fertilizers or pesticides around water, drains, lawn grounds or if rain is predicted within 24 hours. Avoid using copper sulfate root killing products. Pesticides that contain diazinon or chlorpyrifos have been banned and should be disposed of at your local Household Hazardous Waste* collection center or event.

Integrated Pest Management (IPM)
IPM is an eco-friendly approach to effective pest management. Its goal is to use less toxic methods to reduce the use of pesticides, creating a system that is safe for your family and the environment. To learn more, go to the UC Davis IPM resource site at ipm.ucdavis.edu.

Maintenance
Clear, mow and recycle yard debris such as leaves and grass clippings by placing them in your yard waste bin or by composting. Even organic waste, when flushed or blown into storm drains, can create flooding and pollute the watershed. Rotting plant material can also reduce the oxygen available for aquatic wildlife and increase the presence of harmful bacteria.

*Do not dispose of any liquids and items of Household Hazardous Waste collection centers and events throughout Ventura County.

RISK DETERMINATION: Sediment and Receiving Water Risk Level: One Two Three

DEWATERING ACTIVITIES: Has a NPDES Permit been filed: Yes No If yes, is the Permit on site: Yes No

YES	NO	N/A	INSPECTION CRITERIA
			1. SITE PLAN: Does the site plan reflect the project site's condition(s)?
			2. SLOPE EROSION MANAGEMENT: Are slope erosion management BMP's in place per the SWPCP/SWPPP
			3. SEDIMENT TRAPPING: Are all sandbags, straw bales, and/or silt fences in place and are they functioning properly?
			4. SEDIMENT BASINS: If desilting or sediment basins are being used, are they functioning properly?
			5. SEDIMENT MANAGEMENT AT DRAINAGE DISCHARGE POINTS: Are the drainage discharge points reasonably free of any significant erosion or sediment transport?
			6. SITE SEDIMENT MANAGEMENT: Is sediment, debris, or mud contained within the site?
			7. PUBLIC ROAD SEDIMENT MANAGEMENT: Are ingress and egress locations to the construction area stabilized to prevent the tracking of construction materials offsite or onto impervious areas?
			8. MATERIALS MANAGEMENT: Are material handling and storage areas reasonably clean and free of spills, leaks, or any other harmful materials?
			9. MATERIALS MAINTENANCE: Are all materials properly covered/contained?
			10. DESIGNATED MATERIAL STORAGE AREA: Are all locations of temporary soil stockpiles or construction materials in approved areas?
			11. VEHICLE & EQUIPMENT MAINTENANCE: Are all the equipment storage, cleaning, fueling, and maintenance areas reasonably clean and free of spills, leaks, or any other harmful materials?
			12. PAINT, CONCRETE & SAW CUTTING WASTE MANAGEMENT: Are waste containment areas functioning properly?
			13. BMP IMPLEMENTATION: Has an effective combination of BMPs been selected for the project site?
			14. BMP INSTALLATION & MAINTENANCE: Are the BMPs identified on the SWPCP/SWPPP, and/or installed in the proper location according to plan specifications?
			15. POST-CONSTRUCTION BMPs: Have post-construction BMPs been inspected prior to issuing the Certificate of Occupancy?
			16. HIGH RISK SITES: Has the project proponent's qualified SWPPP personnel inspected the site's BMPs during installation and weekly during the wet season (October-April)?
			17. BMP LOG: Is a log kept on site which indicates BMPs are being evaluated, maintained and/or modified in the event that they fail or are not appropriate?
			18. ILLCIT DISCHARGE (CIP): Is non-stormwater runoff leaving the site?
			19. PUBLIC PROJECT (CIP) SWPPP/PCP: Does the SWPPP/PCP have the required training and inspection records?

Attachment D - Illicit Discharge Field Screening Protocol

Attachment D Illicit discharge Field Screening Protocol

Draft 10-Mar-2010

ILLICIT CONNECTIONS AND ILLICIT DISCHARGES (IC/IDS) ELIMINATION PROGRAM

FIELD SCREENING PROTOCOL

PERMITTEE'S NAME

1.0 PURPOSE AND OBJECTIVES

This Field Screening Protocol was prepared by the *Permittee's Name*. The purpose of this Field Screening Protocol is to present *Permittee's Name's* approach and procedures to complete illicit connections and illicit discharges (IC/IDs) field screening requirements under the Los Angeles Regional Water Quality Control Board Order No. 09-0057, National Pollutant Discharge Elimination System (NPDES) Permit No. CAS004002, Waste Discharge Requirements for the Stormwater (Wet Weather) and Non-Stormwater (Dry Weather) Discharges from the Municipal Separate Storm Sewer Systems (MS4) NPDES Permit (Permit) within the Ventura County Watershed Protection District, County of Ventura, and the Incorporated Cities therein. Implementation of the Ventura County MS4 Permit is directed by the Ventura Countywide Storm Water Quality Management Program formed by the Ventura County Watershed Protection District, County of Ventura, cities of Camarillo, Fillmore, Moorpark, Ojai, Oxnard, Port Hueneme, San Buenaventura (Ventura), Santa Paula, Simi Valley, and Thousand Oaks.

2.0 IC/ID ELIMINATION PROGRAM REQUIREMENTS

The following is taken verbatim from the Subpart 4.H. of the Ventura County MS4 Permit. Each Permittee shall implement an IC/IDs program to eliminate, document, track, and report IC/IDs to the storm drain system, as follows:

1. General

- a) Implementation - Each Permittee shall implement an IC/ID Program. The IC/ID procedures shall be documented and made available for public review.
- b) Tracking - All Permittees shall, no later than May 7, 2012, map at a scale and in a format specified by the Principal Permittee all known connections to their storm drain system. **All Permittees shall map at a scale and in a format specified by the Principal Permittee incidents of illicit connections and discharges since January 2009 on their baseline maps, and shall transmit this information to the Principal Permittee no later than May 7, 2012.** Permittees shall use this information to identify priority areas for further investigation and elimination of IC/IDs.

Attachment D Illicit discharge Field Screening Protocol

Draft 10-Mar-2010

2. Public Reporting

- a) Permittees shall establish and maintain a phone hotline and internet site to receive all reports of IC/ID complaints.
- b) Permittees shall document the location of the reported IC/ID and the actions undertaken in response to all IC/ID complaints.

3. Illicit Connections

- a) Screening for Illicit Connections
 - (1) Each Permittee shall submit to the Principal Permittee:
 - (A) A map at a scale and in a format specified by the Principal Permittee showing the location and length of underground pipes 18 inches and greater in diameter, and channels within their permitted area and operated by the Permittee in accordance with the following schedule:
 - (i) All channeled portions of the storm drain system no later than May 7, 2010.
 - (ii) All portions of the storm drain system consisting of storm drain pipes 36 inches in diameter or greater, no later than May 7, 2012. This provision is not meant to exclude Permittees from using equally effective alternative methods not listed in the manual.
 - (iii) All portions of the storm drain system consisting of storm drain pipes 18 inches in diameter or greater, no later than May 7, 2014.
 - (B) The status of suspected, confirmed, and terminated illicit connections.
 - (2) Permittees shall conduct field screening of their storm drain systems in accordance with screening procedures described in the *Illicit Discharge Detection and Elimination, A Guidance Manual for Program Development and Technical Assessments* (2004)¹. Permittees shall conduct field screening of their storm drain system that has not been previously screened and reported to the Regional Board, for illicit connections in accordance with the following schedule:
 - (A) All portions of the storm drain system consisting of storm drain pipes 36 inches in diameter or greater, no later than May 7, 2012.
 - (B) High priority areas identified during the mapping of illicit connections and discharges, no later than May 7, 2012.
 - (C) All portions of storm drain systems 50 years or older in age, no later than May 7, 2012.
 - (3) Each Permittee shall maintain a list containing all connections under investigation for possible illicit connection and their status.

¹ *Illicit Discharge Detection and Elimination, A Guidance Manual for Program Development and Technical Assessments*. The Center for Watershed Protection, PWS R., October 2004. Chapter 13, 13.1, 13.2, 13.3, 13.4

Attachment D Illicit discharge Field Screening Protocol

Draft 10-Mar-2010

b) Response to Illicit Connections

(1) Investigation -

Each Permittee, upon discovery or upon receiving a report of a suspected illicit connection, shall complete an investigation within 21 days, to determine the following:

- (A) Source of the connection.
- (B) Nature and volume of discharge through the connection.
- (C) Responsible party for the connection.

(2) Termination -

Each Permittee, upon confirmation of an illicit storm drain connection, shall ensure the following:

- (A) Termination of the connection within 180 days of completion of the investigation, using formal enforcement authority to eliminate the illicit connection.

(3) Documentation -

Each Permittee shall keep records of all illicit connection investigations and the formal enforcement taken to eliminate all illicit connections.

4. *Illicit Discharges*

(a) Investigation -

Each Permittee shall investigate an illicit/ illegal discharge during or immediately following containment and cleanup activities, and shall take appropriate enforcement action to eliminate the illegal discharge.

(b) Abatement and Cleanup -

Each Permittee shall respond, within 1 business day of discovery or a report of a suspected illicit/ illegal discharge, with actions to abate, contain, and/or clean up all illegal discharges, including hazardous waste.

DEFINITIONS

Channel - means an open conduit either naturally or artificially created which periodically or continuously contains moving water, or which forms a connecting link between two waterbodies.

Illegal Discharge - means any discharge to the municipal separate storm sewer (storm drain system) that is prohibited under local, state, or federal statutes, ordinances, codes, or regulations. The term illegal discharge includes all non-storm water discharges not composed entirely of storm water except discharges pursuant to an NPDES permit, discharges that are identified in part 1, "Discharge Prohibitions" of this order, or discharges authorized by the Regional Water Board Executive Officer.

Illicit Connection - means any engineered conveyance that is connected to the storm drain system without a permit or municipal authorization. It also means any engineered conveyance through which

Attachment D Illicit discharge Field Screening Protocol

~~Draft 10-Mar-2010~~

discharges of pollutants to the separate storm drainage systems, which are not composed entirely of storm water or are not authorized by an NPDES permit, may occur.

Illicit Discharge - means any discharge to a municipal separate storm sewer (storm drain system) that is prohibited under local, state, or federal statutes, ordinances, codes, or regulations. The term illicit discharge includes all non-storm water discharges not composed entirely of storm water except discharges pursuant to a NPDES permit (other than the NPDES permit for discharges from the municipal separate storm sewer) and discharges that are identified in part 1, "Discharge Prohibitions" of this order, or authorized by the Regional Water Board Executive Officer.

Illicit Disposal - means any disposal, either intentionally or unintentionally, of material(s) or waste(s) that can pollute storm water.

Open Channel - means a storm drainage channel that is not a natural water course.

Screening - means using proactive methods to identify illicit connections through a continuously narrowing process. The methods may include: performing baseline monitoring of open channels, conducting special investigations using a prioritization approach, analyzing maintenance records for catch basin and storm drain cleaning and operation, and verifying all permitted connections into the storm drains. Special investigation techniques may include: dye testing, visual inspection, smoke testing, flow monitoring, infrared, aerial and thermal photography, and remote control camera operation.

3.0 INFRASTRUCTURE PROFILE

- *Briefly characterize storm drain system and sewers within the MS4 system (size, age, condition)*
- *Useful statistics to consider (number of storm drain outfalls, miles of storm drain pipe, total stream and channel miles, total areas serviced by storm drain, sewer, and septic tanks)*
- *Reference or include maps as appropriate*

4.0 LEGAL AUTHORITY

In accordance with Subpart 3.B of the Ventura County MS4 Permit, each Permittee shall possess the necessary legal authority to prohibit illicit connections and illicit discharges, and to remove illicit connections. To ensure uniform and consistent countywide approach and to provide a legal underpinning to the entire Ventura Countywide NPDES Stormwater Program, a Model Stormwater Quality Ordinance was developed, which was adopted subsequently by all Permittees with some minor jurisdiction-specific changes. The current Stormwater Quality Ordinance was adopted by *Permittee's Name* on *date*.

In addition, each Permittee has designated Authorized Inspector(s) responsible for enforcing the Ordinance. The Authorized Inspector(s) is the person designated to investigate compliance with, detect violations of and/or take actions pursuant to the Ordinance.

Attachment D Illicit discharge Field Screening Protocol

Draft 10-Mar-2010

- *Provide reference to specific sections of the Permittee's Ordinances for IC/ID prohibition, elimination and enforcement actions,*
- *Determine if any permits are required to implement IC/ID Plan,*
- *Determine if effective inter-departmental coordination and cooperation currently occur*
- *Summarize enforcement capability or include enforcement plan if available*

5.0 MAPPING

As listed in the Section 2 of this Protocol, item a).(1).(A) in paragraph 3 "Illicit Connections", the Ventura County MS4 Permit contains specific mapping requirements including due dates for submittal of the required maps to the Principal Permittee. *Permittee's Name* is in the process of mapping all known connections within its jurisdiction.

- *Summarize current status of your mapping efforts*
- *Are maps of the storm drain system readily available?*
- *Determine system gaps that require mapping; describe how maps will be updated*
- *Determine if storm drain maps include coverage of sanitary and storm sewer networks*

6.0 STAFF ASSIGNED FOR FIELD SCREENING

The *Permittee's Name* selected the following staff to complete field and office assignments as a part of the IC/IDs field screening requirements presented in Section 2 of this Protocol:

Name	Position	Organization	Phone Number	Responsibility

The staff selected for field and office assignments will have adequate training to follow this Field Screening Protocol and ensure compliance with the Ventura County MS4 Permit. The training will include basic field training, inspection, data collection, health and safety, and operation and calibration of field instruments.

- *Determine staff needs to complete field work*
- *Determine staff needs to complete data analysis and reporting*

7.0 IC/ID TRACKING AND ELIMINATION CAPABILITY

In order to meet Ventura County MS4 Permit requirements presented in Section 2 of this Protocol, the *Permittee's Name* selected the following individuals to support implementation of the IC/IDs Elimination Program:

Attachment D Illicit discharge Field Screening Protocol

Draft 10-Mar-2010

Name	Position	Affiliation	Phone Number	Responsibility

The proposed staff and contractors are appropriately trained to respond to IC/IDs, spills, overflows, hazardous material emergencies that occur within *Permittee's Name's* jurisdiction. In the event that IC/IDs investigation and elimination involves more than one Permittee, the contact information presented in [Table 1](#) should be used for notification. Each involved Permittee will be notified as responsible parties are identified.

- *Define responsibilities of Agency(ies), assigned personnel, pre-approved contractors to respond to spills, overflows, hazardous material emergencies,*
- *Determine if personnel is properly equipped and trained to respond to illicit connection*
- *Define strategy for keeping information up-to-date*
- *Define strategy for sharing tracking information among Agencies involved*

8.0 FIELD INSTRUMENTS AND ANALYTICAL LABORATORY

The following field instruments are identified as required and available to complete IC/IDs requirements of the Ventura County MS4 Permit presented in [Section 2](#) of this Protocol:

Field Instrument	Parameters to be Measured	Technical Specifications	Calibration Information
		Exhibit A	Exhibit A

In the event that water sample is required for off-site laboratory analysis, *Permittee's Name* has an on-going contract with *Laboratory Name*. The laboratory contact name is _____ and he/she can be reached at _____. Sample collection details are provided in [Exhibit B](#). Results of lab analysis will be provided to _____ for data analysis and implementation as described in [Section 10](#).

- *Determine requirements for field instruments*
- *Provide calibration procedures and forms*
- *Provide contact and contract information for the analytical laboratory*
- *Provide a sample collection checklist and chain-of-custody forms*

9.0 EDUCATION AND OUTREACH

Public Education is an essential part of a municipal stormwater program because changing public behavior can create a real reduction in environmental pollution. When a community has a clear understanding of where the pollution comes from, how it can affect them and what they can do to stop

Attachment D Illicit discharge Field Screening Protocol

Draft 10-Mar-2010

it, they will be more likely to support the program, change their own practices, and help educate others.

The on-going countywide outreach campaign includes the following key elements:

- Watershed Awareness
- Public Awareness Surveys
- Identification of general and specific goals of the program
- Identification of target audiences and key messages for those audiences
- Development of program strategies and plan overview
- Pollution prevention program using a unified "brand name"
- Development of a watershed based outreach program
- Identification of opportunities to reach out to regulatory agencies
- Development of a model public education/public participation strategy for localization at the Permittee level
- Development and implementation of a school-aged children education outreach program
- Development and implementation of food facilities outreach program materials
- Development and implementation of automotive facilities outreach program materials
- Development and implementation of industrial facilities outreach program materials

The public outreach materials are available at http://www.vcstormwater.org/programs_residential.html

Permittee's Name have established a hotline at (805) XX-XXXX for illicit discharge reporting that has enabled easy reporting and improved response hotline.

- *Determine availability of*
 - *Hotline*
 - *Website to post outreach materials*
 - *Any community events to spread the message*
 - *Outreach materials*

Attachment D Illicit discharge Field Screening Protocol

Draft 10-Mar-2010

10.0 IMPLEMENTATION PLAN

10.1 General

Permittee's Name will complete field screening of its storm drain system **no later than May 7, 2012**. Based on Ventura County MS4 Permit requirements, the screening will include the following system portions that have not been previously screened for illicit connections:

- a) All portions of the storm drain system consisting of storm drain pipes 36 inches in diameter or greater;
- b) High priority areas identified during the mapping of illicit connections and discharges; and
- c) All portions of storm drain systems 50 years or older in age.

In addition, *Permittee's Name* continues responding to IC/IDs discovered during the industrial/commercial business inspections, its routine operation and maintenance activities, or as reported by the public.

10.2 Desktop Assessment to Support Field Screening (Optional)

Desktop Assessment provides a prioritization approach for completing screening requirements within the *Permittee's Name's* jurisdiction. The EPA Guidance recommends Desktop Assessment for municipalities with 20 or more stream miles of the storm drain system required for ID/IC screening.

Desktop Assessment was used by *Permittee's Name* to define where to begin searching for IC/ID problems in *Permittee's Name's* community. It involved processing and analysis of available mapping data to quickly characterize and screen for IC/ID problems at the community and subwatershed scale. Key factors considered in the analysis included *water quality, land use, development age, sewer infrastructure, and outfall density*.

In accordance with *Illicit Discharge Detection and Elimination, A Guidance Manual for Program Development and Technical Assessments* (2004) the following 5 steps were applied:

Step 1: Delineate subwatersheds

Permittee's Name delineated the following subwatersheds *or other drainage units* within the community, refer to [Map X](#):

- 1)
 - + *List defined subwatersheds or drainage units*

Attachment D Illicit discharge Field Screening Protocol

Draft 10-Mar-2010

Step 2: Compile mapping layers and subwatershed data

Permittee's Name compiled available maps (Section 5) and data for each drainage unit (e.g., land use, age, outfalls, infrastructure history).

- *Summarize results of the map analysis; include layered maps if available.*

Step 3: Compute discharge screening factors (SF)

Out of 10 screening factors discussed in the EPA's Guidance Manual, *Permittee's Name* selected the following factors for the IC/ID problem analysis:

- Past Discharge Complaints and Reports
- Poor Dry Weather Water Quality
- Density of Generating Sites or Industrial NPDES Storm Water Permits
- Storm Water Outfall Density
- Age of Subwatershed Development
- Sewer Conversion
- Historic Combined Sewer Systems
- Presence of Older Industrial Operations
- Aging or Failing Sewer Infrastructure
- Density of Aging Septic Systems

The following are results of the SF analysis for *Permittee's Name's* community:

	SF 1	SF2	SF3	Raw IC/ID Problem Score	Normalized IC/ID Problem Score
<i>Subwatershed A</i>					
<i>Subwatershed B</i>					

Example

Basis for assigning scores (based on benchmarks) to assess IDP is as follows:

Past discharge complaints/reports: <5 = 1; 5-10 = 2; >10 = 3
 Dry weather water quality: <25% = 1; 25-50% = 2; >50% = 3
 Storm water outfall density: <10 = 1; 10-20 = 2; >20 = 3
 Average age of development: <25 = 1; 25- 50 = 2; > 50 = 3

- *Checked selected factors*
- + *Complete table:*

Step 4: Screening at the subwatershed and community level

Screen and rank illicit discharge potential at the subwatershed and community level

Attachment D Illicit discharge Field Screening Protocol

Draft 10-Mar-2010

The raw score values of the IC/ID potential problems were re-evaluated using SF data at the subwatershed and community level resulting in normalized scores listed above. Based on *Permittee's Name's* analysis, the following prioritization of the risk was determined:

- Highest risk at *Subwatershed X*
- Medium risk at *Subwatershed Y*
- Low risk at *Subwatershed Z*

Step 5: Generate maps to support field investigations

Incorporating all the Desktop Assessment results, *Permittee's Name* determined that communities A and B have minimal IC/ID problems, C and D exhibit clustered IC/ID problems, and E and F are of severe IC/ID problems, refer to *Map(s)*.

The desktop assessment completed by *Permittee's Name* is used to guide field screening by generating the following outcomes:

- 1) Screening problem catchments or subwatersheds,
- 2) Creation of GIS or other database system to track outfalls,
- 3) Gaining an overall assessment as to the severity of illicit discharge problems in the community, and
- 4) Generation of basic mapping for subsequent field work

10.3 Field Screening Methodology

The primary field screening tool recommended by the EPA IDDE Guidelines is the Outfall Reconnaissance Inventory (ORI), which is used to find IC/ID problems, develop a systematic outfall inventory, and map or verify existing maps of the MS4. The ORI is a stream walk designed to inventory and measure storm drain outfalls, and find and correct continuous and intermittent discharges and illicit connections.

During ORI walk, *Permittee's Name's* trained staff will use EPA's "Outfall Reconnaissance Inventory Field Sheets" provided in Exhibit C to record field information. These sheets will facilitate recording outfall locations and characteristics. Field crew will describe the following indicators for flowing and non-flowing outfalls as listed in the "Outfall Reconnaissance Inventory Field Sheets":

1. Odor (flowing outfalls only);
2. Color (flowing outfalls only);
3. Turbidity (flowing outfalls only);
4. Floatables (flowing outfalls only);
5. Outfall damage (both flowing and non-flowing outfalls);

Attachment D Illicit discharge Field Screening Protocol

Draft 10-Mar-2010

6. Deposits/stains (both flowing and non-flowing outfalls);
7. Abnormal vegetation (both flowing and non-flowing outfalls);
8. Poor pool quality (both flowing and non-flowing outfalls), and
9. Pipe benthic/algal growth (both flowing and non-flowing outfalls).

Permittee's Name will compile ORI data including field information, GPS data, and photographs of outfall locations.

The ORI can discover obvious discharges that are indicated by flowing outfalls with very high turbidity, strong odors and colors, or an "off the chart" value on a simple field test strip. When obvious discharges are found and physical indicators are present, refer to Figure 1 "Illicit Discharge Source Investigation Flow Chart", field crews will initiate response within 1 business day. ORI crews may also encounter a discharge of hazardous materials or wastewater that should be immediately referred to the appropriate agency for cleanup, refer Table 1 "Ventura County Illicit Discharge Response Contact List".

In order to complete investigation of the IC/ID source, *Permittee's Name* will select appropriate Investigative method from the following methods recommended in the US EPA Guidance Manual:

- Storm Drain Network Investigation (refer to subsection 10.3.1);
- Drainage Area Investigation (refer to subsection 10.3.2);
- On-site investigations (refer to subsection 10.3.3); and
- Septic system investigations (refer to subsection 10.3.4).

Detailed descriptions of the methods are provided in Chapter 13 of the *Illicit Discharge Detection and Elimination, A Guidance Manual for Program Development and Technical Assessments* (2004).

IC/ID discovery, investigation, and response will be documented using forms provided in Exhibit C. Appropriate information will be provided to Regional Water Quality Control Board in the Annual Report. In addition, per Permit requirements, *Permittee's Name* will map incidents of illicit connections and discharges since January 2009 on its baseline maps and transmit this information to the Principal Permittee no later than May 7, 2012.

10.3.1 Storm Drain Network Investigation

Field crews will strategically inspect manholes within the storm drain network system to measure chemical or physical indicators that can isolate discharges to a specific segment of the network. Once the pipe segment is identified, on-site investigations will be used to find the specific discharge or improper connection.

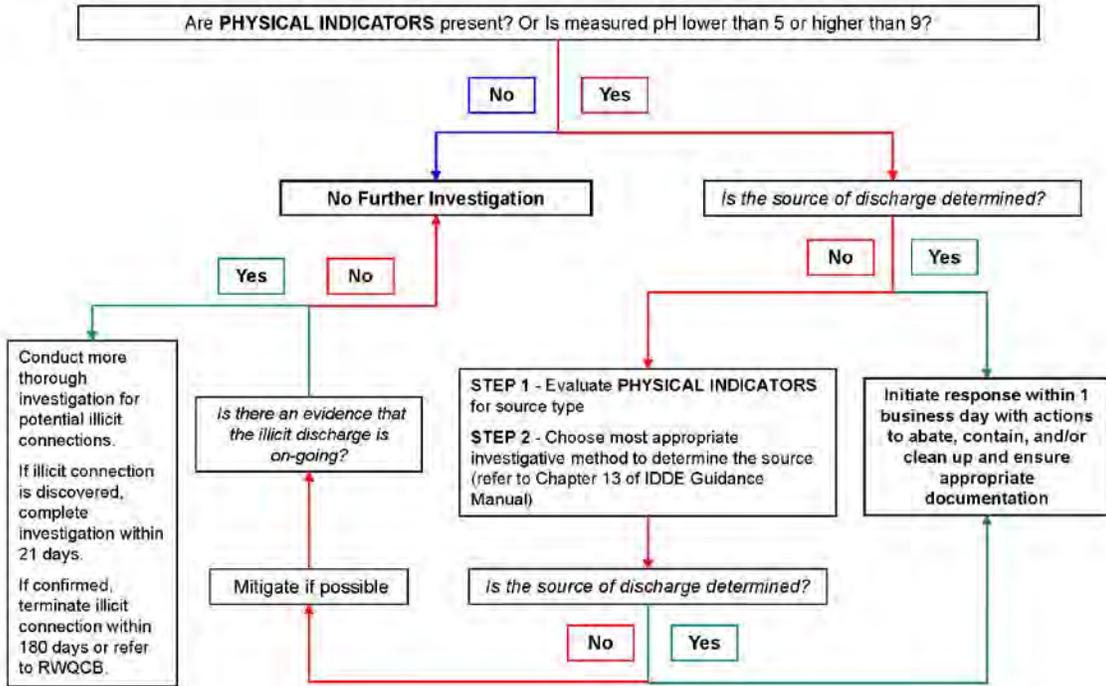

This method involves progressive visual inspections and/or sampling at manholes in the storm drain network to narrow the discharge to an isolated pipe segment between two manholes. When conducting a storm drain network investigation, field crews need to decide where and how to proceed with visual inspections and/or sampling in the network.

Attachment D Illicit discharge Field Screening Protocol

Figure 1 Illicit Discharge Source Investigation Flow Chart

STEP 1 – Complete Outfall Reconnaissance Inventory Field Sheet

STEP 2 – Notify other Permittees if observed discharge is present in their facilities

Attachment D Illicit discharge Field Screening Protocol

Draft 10-Mar-2010

The field crew should decide how to attack the pipe network that contributes to a problem outfall. Three options can be used:

- 1) Crews can work progressively up the trunk from the outfall and test manholes along the way.
- 2) Crews can split the trunk into equal segments and test manholes at strategic junctions in the storm drain system.
- 3) Crews can work progressively down from the upper parts of the storm drain network toward the problem outfall.

10.3.2 Drainage Area Investigation

This method relies on an analysis of land use or other characteristics of the drainage area that is producing the illicit discharge. The investigation can be as simple as a "windshield" survey of the drainage area or a more complex mapping analysis of the storm drain network and potential generating sites. Drainage area investigations work best when prior indicator monitoring reveals strong clues as to the likely generating site producing the discharge.

10.3.3 On-site Investigation (Optional)

On-site methods are used to trace the source of an illicit discharge in a pipe segment, and may involve dye, video or smoke testing within isolated segments of the storm drain network. While each approach can determine the actual source of a discharge, each needs to be applied under the right conditions and test limitations discussed in details in Chapter 13 of the *Illicit Discharge Detection and Elimination, A Guidance Manual for Program Development and Technical Assessments* (2004). It should be noted that on-site investigations are not particularly effective in finding *indirect* discharges to the storm drain network.

10.3.4 Septic System Investigation (Optional)

Low-density residential watersheds may require special investigation methods if they are not served by sanitary sewers and/ or storm water is conveyed in ditches or swales. The major illicit discharges found in low-density development are failing septic systems and illegal dumping. Homeowner surveys, surface inspections and infrared photography have all been effectively used to find failing septic systems in low-density watersheds.

10.4 Health and Safety Considerations

The field crew (2 staff at minimum) will be trained to raise awareness of many hazardous circumstances that they may confront when conducting field screening of the storm drain system. These health and safety guidelines can only be effective, however, if they are considered, discussed, and applied with a large dose of prudent judgment.

Communication is also a major component. When doubts and concerns arise, field crew will discuss the matter with a supervisor. Furthermore, always err on the side of safety when assessing risk. If there is any doubt whether task can be safely performed, ask the crew leader/supervisor for further instructions and help. Protecting personal safety is more important than completing a risky task – SAFETY FIRST!

ATTACHMENT 54

Los Angeles Regional Water Quality Control Board

June 4, 2015

Mr. Gerhardt Hubner
Deputy Director
Ventura County Watershed Protection District
800 S. Victoria Avenue
Ventura, CA 93009

RESPONSE TO REQUEST TO CONFIRM LEVEL OF EFFORT PRESCRIBED IN ORDER NO. R4-2010-0108, ATTACHMENT F, SECTION I.1.a.1.a.i, IN ACCORDANCE WITH NEW FIVE YEAR STUDY DESIGN FOR SMC REGIONAL BIOASSESSMENT PROGRAM

Dear Mr. Hubner:

We have received your request to confirm the level of effort required by the Ventura Countywide MS4 Permit Order No. R4-2010-0108 (Ventura County MS4 Permit) for bioassessment that will be met by implementing the new five-year study design for the Regional Bioassessment Program (Regional Program).

Attachment F, Section 1, of the Ventura County MS4 Permit, requires Permittees to participate in the Southern California Municipal Storm Water Monitoring Coalition's (SMC) Regional Bioassessment Program, which requires Permittees to conduct bioassessment monitoring at specified sites in Ventura County as part of the Regional Program. The Regional Program study, that was in effect at the time of the Ventura MS4 Permit issuance, was completed in 2013.

Ventura County Watershed Protection District's participation in the Regional Program was required to provide a level of effort that would fully support the Regional Program to prevent any data gaps in Ventura County. Understanding that the original Regional Program five-year study design (2009-2013) has been completed, and the Regional Program has been modified for 2015-2020, the specific level of effort described per watershed Attachment F, Section 1, of the Ventura County MS4 Permit, no longer reflects the current SMC Regional Program.

In your letter, requesting confirmation of bioassessment efforts required of the Ventura County Watershed Protection District, you note that 15 sites will be monitored but the location of the sites will be revised in accordance with the Regional Program design. As noted, this does not change the overall sampling effort, nor does it reduce the required effort at integrator sites.

The Regional Water Board Executive Officer or the Regional Board, consistent with 40 CFR 122.41, may approve changes to the Monitoring Program, after providing the opportunity for public comment, either:

- (a) By petition of the Principal Permittee or by petition of interested parties after submittal of the Monitoring Report. Such petition shall be filed not later than 60 days after the Monitoring Report submittal date, or
- (b) As deemed necessary by the Regional Water Board Executive Officer following notice to the Principal Permittee.

Pursuant to Part 7.C.2 of the Ventura County MS4 Permit, a 30-day public comment period is required prior to the Executive Officer's approval of the revised bioassessment monitoring sites. The public comment period will begin when the public notice is published on the Water Board's website. Your staff will be notified immediately prior to opening of the public comment period and the web posting of your letter requesting confirmation of your revised participation in the Regional Program:

http://www.waterboards.ca.gov/losangeles/water_issues/programs/stormwater/municipal/index.shtml#ventura

If you should have any questions regarding this letter please feel free to call me at (213) 576-6605 or your staff may contact Ivar Ridgeway at (213) 620-2150.

Sincerely,

Samuel Unger, P.E.
Executive Officer

cc: Ventura County MS4 Co-Permittees

ATTACHMENT 55

RETAIL GASOLINE OUTLETS: NEW DEVELOPMENT DESIGN STANDARDS FOR MITIGATION OF STORM WATER IMPACTS

Technical Report

June 2001

Dan Radulescu, and Xavier Swamikannu
California Water Quality Control Board, Los Angeles Region
320 W. 4th Street, Suite 200
Los Angeles, CA 90013

Phil Hammer
California Water Quality Control Board, San Diego Region
9771 Clairemont Mesa Blvd, Suite A
San Diego, CA 92124

Introduction

On March 8, 2000, the California Regional Water Quality Control Board, Los Angeles Region (LA Regional Board) issued requirements for new development and significant redevelopment consolidated in a Standard Urban Storm Water Mitigation Plan (SUSMP). The SUSMP included requirements for retail gasoline outlets (RGOs), commonly referred to as “gas stations”, among several other development categories. Several municipalities, the Building Industry of Southern California (BIA), and the Western States Petroleum Association (WSPA) appealed the action of the LA Regional Board to the State Water Resources Control Board (State Board) for review. The State Board issued its decision *In Re City of Bellflower et al.* (SUSMP Decision) in large part upholding the action of the LA Regional Board.

In its Order, the State Board set aside the numerical mitigation requirement for RGOs explaining that the decision did not preclude future inclusion of numerical mitigation standards for RGOs with proper justification.

On February 21, 2001, the California Regional Water Quality Control Board, San Diego Region (SD Regional Board) issued an MS4 permit for San Diego County and Cities which includes requirements for new development and significant redevelopment. The MS4 permit requires Permittees to develop a model SUSMP no later than February 21, 2002, that will establish new development controls for project categories including RGOs. The SD Regional Board did not propose a threshold for RGOs to apply numerical design standards, giving the MS4 permittees the first option to develop the threshold criterion for RGOs and the justification. On March 22, WSPA filed an appeal of the SD Regional Board action for review before the State Board contending that RGOs were being improperly subject to numerical design standards in the MS4 permit for San Diego County and cities.

Urbanization and Storm Water Quality

Urbanization alters the natural infiltration capability of the land and generates a host of pollutants that are entrained in storm water and urban runoff. These pollutants such as heavy metals and petroleum hydrocarbons result from the activities of dense human populations. The overall impact is an increase in storm water runoff volumes and pollutant loading in storm water discharged to receiving water-bodies.¹

Urban development increases the amount of impervious surface in a watershed as farmland, forests, and meadowlands with natural infiltration characteristics are converted into buildings with rooftops, driveways, sidewalks, roads, and parking lots with virtually no ability to absorb storm water. Storm water and snow-melt runoff wash over these impervious areas, picking up pollutants along the way while gaining speed and volume because of their inability to disperse and filter into the ground. What results are storm water flows that are higher in volume, pollutants, and temperature than the flows in less impervious areas, which have more natural vegetation and soil to filter the runoff.² In addition to impervious areas increase, urban development brings with it proportionately high levels of car emissions, car maintenance waste, pet waste, litter, pesticides, and household hazardous wastes, which may be washed into receiving waters by storm water or dumped directly into storm drains designed to discharge to receiving waters.

Most organic compounds found in storm water are associated with various human-related activities, especially automobile use, or are associated with plastics.³ Heavy metals found in storm water also mostly originate from automobile use activities, including gasoline combustion, brake lining, fluids, undercoatings, and tire wear.⁴

More recently, studies reveal a connection between urban development and contamination of local waterbodies. Studies found the highest levels of organic contaminants, known as polycyclic aromatic hydrocarbons (PAHs) (products of combustion including fossil

fuels combustion), in the reservoirs of urbanized watersheds.⁵ Studies also established a clear relationship between the adverse impact of urbanization and impairment of aquatic communities in receiving waterbodies.⁶

Federal Storm Water Regulations

Federal regulations require that MS4 permittees implement a program to control storm water pollution from new developments during and post-construction. Because there is no express national standard for the control of storm water pollutants from new developments, the permitting authority must defer to statements of policy and intent made by the U.S.EPA.

The U.S.EPA under Phase I regulations did not fully describe the expectations for MS4 Permittees in controlling post construction storm water discharges from new development and significant redevelopment except that “a comprehensive master plan” was required [55 *Fed Reg.* 48054]. For a better understanding of the regulatory expectation, we look to the Final Rule for Phase II storm water regulations. Therein, the U.S.EPA notes that “prior planning and designing for the minimization of pollutants in storm water is the most cost-effective approach to storm water quality management” [64 *Fed Reg.* 68759], and identifies four essential elements to control storm water from new development and redevelopment. These are, (i) to develop and implement strategies that include a combination of structural and non-structural BMPs; (ii) adopt an ordinance to address post construction runoff; (iii) ensure long term operation and maintenance of the BMPs; and (iv) ensure that controls are in place that will *minimize* water quality impacts. [Emphasis added] EPA goes on to say:

“The requirements[are] consistent with the permit application requirements for large MS4s for post-construction controls for new development and redevelopment.”

The permitting authority in order to comply with federal regulations must thus require the implementation of an MS4 program that will achieve all four enumerated objectives for new development and redevelopment. In order for the program to be enforceable, the program for new development and significant redevelopment must include objective criteria such as water quality design standards for treatment-control BMPs, for significant categories of development such as RGOs.

Further, the Federal Court of Appeals has unequivocally stated that Congress intended for “the Administrator or a State to design [substantive] controls” for storm water discharges from MS4s but did not mandate a particular approach [*NRDC v. USEPA*, 966 F.2d 1292 (9th Cir. 1992)]. The court held that it is appropriate to defer to U.S.EPA [and the State] where the agency supplied a “reasoned explanation”.

Also, the USEPA is currently in the process of developing effluent guidelines for the construction and development industry, which will include controls for new development and significant redevelopment.⁷

Retail Gasoline Outlets

RGOs can range in size from about 3,000 square feet to more than 200,000 square feet. The median size of new RGOs in Los Angeles County is about 13,000 square feet.⁸ There are about 2,133 RGOs in Los Angeles County servicing a population of 9.5 million, and nearly six million registered motor vehicles.⁹ In San Diego County there are about 700 RGOs serving a population of 2.8 million, and nearly 2 million registered vehicles.

RGOs are points of confluence for motor vehicles for automotive related services such as repair, refueling, and ancillary services such as tire air inflation and radiator fillup. The vehicular traffic patterns at RGOs are similar to those on parking lots and on highways. Researchers have identified RGOs as toxic pollutant hotspots.¹⁰

Storm Water Quality

RGOs are a well identified source of urban storm water pollutants that impair receiving waters. WSPA has acknowledged that storm water discharges from even “normally operated and maintained” RGOs are no worse than discharges from commercial parking lots and diffuse urban runoff.¹¹ The reason that “normally operated and maintained” RGOs do not demonstrate any improvement in storm water discharge quality is because existing BMPs do not address pollutants generated by motor-vehicle traffic.¹² Heavy metals, significant concentrations of which occur in storm water discharges from RGOs, have been demonstrated to be the main cause of toxicity in Santa Monica Bay during wet weather.¹³ Oil and grease in the storm water discharges from RGOs are also of concern.¹⁴

In a study conducted in Maryland, RGOs were identified to generate significantly higher concentrations of hydrocarbon and heavy metals than parking lots, convenience store lots, and

streets.¹⁵ A study conducted in Sacramento County, California, identified heavy metals such as lead, copper, and zinc, as significant in storm water from RGOs.¹⁶ Volatile organic compounds (VOCs) such as benzene, toluene, ethylbenzene, and xylene are rarely detected in storm water because of their volatility. In contrast, gasoline and other solvents, because of their physical and chemical characteristics, may present a significant risk for groundwater contamination, if underground and aboveground storage tanks leak.

The sources of storm water pollutants at RGO are from tail-pipe exhaust particles, fluid losses, drips, spills, and mechanical, brakepad and tire wear products, which build up on impervious surfaces at RGOs.¹⁷ The pollutants of most concern in storm water are heavy metals such as Pb, Cu, and Zn and petroleum hydrocarbons such as PAHs.¹⁸ The concentration and loads of these pollutants in storm water runoff from RGOs depends on the surface deposition and removal rates, and permanent storage. The permanent storage on surfaces is a function of surface area texture and condition and is literally trapped in the texture or cracks of the surface area. Pollutants are deposited any where vehicles travel, park, or are serviced, including RGOs.¹⁹

Review of New Development Design Standards

WSPA represents petroleum industry members in the States of Arizona, Hawaii, Nevada, Oregon, in addition to California. WSPA in its Petitions before the State Board has contended that new development standards that include numerical design standards for BMPs are impracticable and unnecessary at RGOs, and so we focussed the review on development standards that new RGOs are subject to in Western U.S. States. We are aware that new RGO developments in other States such as Maryland, Virginia, Florida, Alabama, Tennessee, Georgia, Oklahoma and Texas, are also subject to numerical mitigation requirements for storm water pollutants, but we did not review their programs for this technical report.

In Washington, RGOs in the western region that create impervious surfaces of 5,000 square feet or more are required to mitigate the 6 month 24 hour storm (about 1.2 inches of rainfall). In addition to the standard treatment menu based on a water quality design storm,

¹⁵ *Hydrocarbon Hotspots in the Urban Landscape*, Shueler T., and Shepp, D., (1995), pp. 259-264, *National Conference on Urban Runoff Management: Enhancing Urban Watershed Management at the Local, County and State Levels*, Chicago, IL, Report No. EPA/625/R-95/003. A survey of oil and grit separators in suburban Maryland indicated that RGOs and convenience stores had much higher levels of hydrocarbons and metals both in the water column and the sediments.

¹⁶ *Action Plan Demonstration Project (APDP) - Demonstration of Gasoline Fueling Station Best Management Practices*, County of Sacramento, (1994), pp. 30 Submitted to US EPA Region IX, San Francisco Estuary Project.. This study funded by the USEPA and conducted by Sacramento County identified heavy metals such as lead, copper, and zinc in significant concentrations in storm water runoff from RGOs. Volatile Organic Compounds (VOCs) from fueling areas were rarely detected because of their volatility. Data on Polycyclic Aromatic Hydrocarbons (PAHs) was inconclusive because analytical detection limits used were higher than regulatory action levels.

RGOs that are expected to generate ADT of 100 vehicles or more per 1,000 square feet of gross building area are required separately to treat to remove oil.²⁰ The City of Portland in Oregon under its MS4 program requires RGOs to mitigate storm water runoff from impervious areas equal to or greater than 500 square feet using any one of three different design approaches.²¹ One of the choices is the 24-hour rainfall event standard (0.83 inch of rainfall). In addition, RGOs that are expected to generate 100 vehicles or more ADT per 1000 square feet of gross building area are subject to separate treatment controls for oil using a water quality design standard of a two year 24 hour storm.²² In both Washington and Oregon, storm water treatment is required in addition to the source control BMPs identified by WSPA for implementation at its facilities in California.²³

Treatment Control BMPs

The U.S. EPA funded a demonstration project to evaluate the effectiveness of on-line media filter media to treat pollutants from storm discharges at RGOs.²⁴ Four on-line media filter systems were tested and the study concluded that the treatment systems had sufficient ability to remove pollutants without risk of flooding, were easy to operate and maintain, and reasonable in capital cost.

We also reviewed storm water quality data results evaluating the pollutant removal effectiveness of a proprietary on-line filter media device located at a large RGO in Washington.²⁵ The device was installed underground and thus occupied no surface area. The treatment device was effective in removing between 50 and 90 percent of pollutants of concern in storm water discharges from RGOs. We note with interest that in perusing the treatment devices installation list of this proprietary manufacturer between 1997 and 2001 in the Western U.S., California had not a single installation at an RGO but Oregon and Washington had a combined total of 13 RGO sites where the treatment devices were installed. Considering that RGOs in the State of Washington and Oregon have ADT that is much less than in California, the aberration can only be explained by the lack of rigorous storm water regulatory controls in California to control the discharge of pollutants in storm water discharges from RGOs.²⁶

Our review indicates that effective treatment devices for RGOs include on-line media filter systems with a combination of media placed in series to remove the pollutants of concern.

²⁰ Such sites are considered “high use sites” because they typically generate high concentrations of oil from traffic turnover. See Stormwater Management Manual for Western Washington, Vol. V, Runoff Treatment BMPs, (2000), Washington Department of Ecology, p 145.

²¹ Stormwater Management Manual, City of Portland, OR, (2000), p 1-11.

²² Ibid. at page 9-47. Sites that meet the threshold are considered “higher risk categories”.

Sand filters are another option. There may be other treatment control BMPs that may be equally if not more effective.²⁷

Economic Considerations

A review of costs of storm water treatment controls for RGOs indicates that the cost of storm water treatment is reasonable.²⁸ In addition, a demonstration project sponsored by the USEPA to evaluate the effectiveness and costs of on-line media filters placed the first year capital cost between \$250 and \$900 and an operations and maintenance cost of \$240 annually.²⁹

Justification

The State Board in its SUSMP Decision temporarily excluded RGOs from the numerical mitigation standard until Regional Boards provided proper justification and established appropriate thresholds. Issues to be considered included presumptions that RGOs were, (i) already heavily regulated; (ii) limited in their ability to construct infiltration BMPs; (iii) generally small in size; and (iv) storm water treatment may not be feasible or safe.

Over-regulation:³⁰ Under State law, the State Board and Regional Boards are the primary authorities for implementation of the federal Clean Water Act, and for matters related to water quality within the State.³¹ There is no basis in federal or State statute that permits the State Board or Regional Boards to abdicate their water quality authority because discharges from facilities that impact water quality are already regulated for other purposes. Attainment and maintenance of receiving water objectives and the protection of beneficial uses are the paramount considerations.

Limitations of space or ability: Our review indicates that RGOs appear not to be limited by space or ability to treat storm water. The surface area of RGO developments is generally greater

²⁷ For a list of potential treatment options see, Storm Water Manual for Western Washington Vol. V, - Runoff Treatment BMPs, Washington Dept. Ecology (2000).

²⁸ See "Cost and Benefits of Storm Water BMPs", Preliminary Data Summary of Urban Storm Water Best Management Practices, USEPA, (1999) Report No. EPA-821-R-99-0012, pp. 6-1 – 6-44.

³⁰ The Regional Board's review of regulations that affect RGOs identified, (i) business license for business operation, (ii) Fire Department for tank/ piping integrity and gasoline storage; (iii) County Public Works for underground storage of hazardous chemicals; (iv) Air Quality Management District for VOC emissions; (v) Sanitation District for any sanitary sewer discharges; (vi) County Weights and Measures for sale of gasoline; (vi) Department of Toxics Substance Control for waste motor oil disposal; (vii) County Health for food and beverage sale; and (viii) Regional Board for regulation of leaking tanks to protect groundwater.

³¹ Cal. Wat. Code § 13160 states that, "the State Board is designated as the state water pollution control authority for all purposes.... in federal act." Cal. Pub. Res. Code § 30412 states that, "other State agencies shall not modify, adopt conditions, or take any action in conflict with any determination by the State Board in matters relating to water quality".

than 5000 square feet. The fabricated storm water treatment systems we reviewed generally do not exceed 128 square feet in surface area when installed and do not impede traffic flow because they are situated sub-surface. While opportunities for infiltration practices may be limited, it is but one type of option for mitigation of pollutants in storm water. The SUSMP does not mandate infiltration BMPs. Other treatment options exist such as fabricated treatment control BMPs to remove storm water runoff pollutants using physical, biological, or chemical processes. Also treatment control BMPs can be installed sub-surface without interfering with surface use. RGOs situated in other Western U.S. States, which have lower impervious surface area and higher water quality treatment volume criteria thresholds already implement storm water treatment controls at new facilities.

Feasibility of storm water treatment: Our review of implementation of storm water treatment control requirements in other Western U.S. States indicates that storm water treatment at RGOs is both feasible and safe. In California, sub-surface fabricated treatment systems have been commonly used at RGOs to separate waste-oil before discharge to the sanitary sewer system. Safety or feasibility has not been an issue when sanitation districts required RGOs to install treatment systems in order to obtain connection permits to the sanitary sewer system. As previously mentioned storm water treatment controls are installed as a matter of practice by RGOs in other Western U.S. States. There is no reason to suppose that storm water treatment in California introduces new and different safety and feasibility considerations, as when compared to wastewater treatment systems which RGOs have readily installed in California and storm water treatment systems installed in other Western U.S. States.

Suggested criteria

Storm water pollution at RGOs is primarily a function of the number of motor vehicles that are refueled or serviced. Ancillary services such as auto repair may additionally contribute significant pollutant loads. A WSPA study concluded that the storm water runoff quality from well-maintained RGOs is comparable in pollutant concentrations to runoff from commercial parking lots.³²

The State Board recommended that the Regional Boards undertake further consideration of a threshold relative to size of RGOs for application of the numerical design standard for storm water. Our analysis indicated the following criteria for thresholds may be appropriate.

Land area: 5,000 square feet or more of impervious area. RGOs in Portland, Oregon and Western Washington that meet this land area threshold are currently subject to storm water treatment requirements based on the water quality design storm.³³

Projected Average Daily Traffic (ADT): 100 or more vehicles fueled per day. The projection for the number of vehicle trips a RGO can expect may be estimated using information published by the Institute of Transportation Engineers. The vehicular traffic at an RGO is a good determinant for the quantity of storm water pollutants generated at the site. RGOs in Oregon and Washington are subject to two tiers of threshold for treatment of storm water, the first based

³² See 'Results of a Retail Gasoline Outlet and Commercial Parking Lot Storm Water Runoff Study (1994)', Western States Petroleum Association, and American Petroleum Institute, 49 p. Commercial parking lots 5,000 square feet or more are presently subject to the SUSMP numerical mitigation standard.

³³ WSPA represents companies that explore, produce, refine, transport and market petroleum in six western states including Oregon, Washington, and California. See www.wspa.org

on the impervious area threshold, and an additional tier storm water treatment requirement for sites that expect 100 vehicles or more ADT per 1,000 square feet of gross building area.³⁴

Projected volume of gasoline sale: 25,000 gallons or more of gasoline sale per month.³⁵
The projected volume of gasoline sales is directly correlated with vehicular trips. 25,000 gallons of gasoline sale per month is equivalent to an average daily traffic of about 100 vehicles.³⁶

Although other criteria such as the number of fueling dispensers (“nozzles”-4 or more) and the number of dispenser meters (12 or more assuming one meter per octane grade), were considered for thresholds, the relationship of such criteria to predict the potential for pollutant generation at RGOs is less direct.

It is recommended that numerical mitigation standards be made applicable, if the RGO development meets the following thresholds, (i) creates 5,000 square feet or more of impervious surface; and (ii) has a projected trip generation of 100 or more motor vehicles ADT.

Conclusion

RGOs have been well documented in the scientific literature as significant sources of storm water pollutants. These pollutants such as heavy metals and PAHs have been known to cause the impairment of beneficial uses in receiving waters. As a source of pollutants, storm water from RGOs is similar to runoff from driveways, roads, highways and parking lots.

In order to reduce the discharge of pollutants in storm water to the MS4, it is technically appropriate to require that new RGOs and significantly redeveloped RGOs be subject to the SUSMP numerical mitigation criteria. RGOs in other Western U.S. States already comply with higher numerical mitigation standards than those established by the LA Regional Board and the SD Regional Board. The treatment of storm water for RGOs is technically feasible, safe, and of reasonable cost.

³⁴ See, Storm Water Management Manual (August 2000), City of Portland, Oregon, (p 9-10) additional thresholds for fuel dispensing facilities. Also, Storm Water Management Manual for Western Washington, Vol. V, Runoff Treatment BMPs, Washington Department of Ecology, p 9-10, additional requirement thresholds for high-use sites.

³⁵ The average volume of gasoline sales at a RGO in California is approximately 100,000 gallons per month. Gasoline stations with outputs of 200,000 or more gallons a month are considered high output facilities by the industry.

³⁶ A typical “full” tank gas refueling is around 8 gallons delivered at a pump. Many RGOs use this benchmark for discount offerings or other type of incentives associated with refueling. 100 cars x 8 gallons per car x 30 days = 24,000 gallons of gasoline per month.

ANNUAL MONITORING REPORT 2001-2002

**Stormwater Monitoring Coalition
Of Southern California**

October 25, 2002

INTRODUCTION

Stormwater runoff in southern California has become one of the largest environmental management issues in the region. While current runoff management has become an immensely successful system for flood control, it has not historically been designed to enhance water quality. Current estimates of pollutant loads from stormwater runoff rival those of traditional point sources for many constituents, and several examples of impacts from storm drains and channels have been observed in receiving waters. Examples include the contribution of bacteria that has resulted in posting of beaches for swimming, contributions of nutrients that have resulted in blooms of macroalgae, and contributions of toxics that has led to aquatic toxicity and degradation of aquatic habitats. This combination of emissions and impacts has led to an increasing regulatory focus on stormwater runoff, but much of the science needed to make effective and efficient management decisions is still lacking.

As a result of the increasing regulatory focus and the lack of scientific knowledge base, both stormwater regulators and municipal stormwater management agencies throughout southern California have developed a collaborative working relationship. The goal of this relationship is to develop the technical information necessary to better understand stormwater mechanisms and impacts, and then develop the tools that will effectively and efficiently improve stormwater decision-making. As individuals and agency representatives, there was early recognition that these issues are oftentimes not localized, but typically cross watershed and jurisdictional boundaries. This relationship culminated in a formal letter of agreement signed by all of the Phase I municipal stormwater NPDES lead permittees and the NPDES regulatory agencies in southern California to create the Stormwater Monitoring Coalition (SMC) (Table 1).

The SMC member agencies have developed a clear vision of regional cooperation. The vision includes combining resources to cost effectively achieve their goal. The vision includes improved effectiveness of existing monitoring programs by promoting standardization, coordination, and reducing duplication of effort across individual programs. This will lead to improving the basic infrastructure for exchanging, combining, and analyzing data from across the region. The multi-agency collaboration hopes to trade off redundant or ineffective monitoring program elements in order to allocate resources to the research projects necessary for improving stormwater management. The findings from these applied research projects can then be easily and quickly integrated into the existing stormwater management programs.

This document outlines the activities that the SMC has accomplished over the last year. The initial project promoted by the SMC was the creation of a research agenda. The SMC has subsequently embraced three of the proposed projects in the research agenda and have begun work to accomplish the project objectives. The SMC meets on a quarterly basis to discuss these projects and ensure their success. Cumulatively, these activities demonstrate that the SMC is an active organization and is making great strides in achieving its stated goals. The common vision shared in by the initial founding members

of the SMC has taken root and is being implemented to the benefit of both regulatory and regulated communities.

YEAR END PROJECT STATUS

Creation of a Stormwater Research Agenda (status: complete)

The first project undertaken by the SMC was to develop a research agenda they could jointly undertake. Creation of this research agenda required careful consideration since this document would form the basis of future activities by the SMC. Therefore, the SMC assembled a panel of 16 experts, in a variety of disciplines, for a 3-day facilitated workshop. These experts included hydrologists, civil engineers, water quality scientists, biologists, toxicologists, statisticians, modelers as well as representatives from the regulatory, regulated and environmental community. The goal of the workshop was to create a list of priority project descriptions including background and objectives, general approach, expected products, as well as a timeline and estimated budget. This project was jointly funded by all SMC sponsoring agencies.

The final research agenda was comprised of 15 distinct projects. The 15 projects fell into a three-part framework that included building a monitoring infrastructure, understanding stormwater mechanisms and processes, and understanding receiving water impacts. Building monitoring infrastructure included projects such as developing standardized sampling and analysis protocols, assessing BMP effectiveness, and examining historical monitoring data. Understanding stormwater mechanisms and processes included projects such as developing a systemwide conceptual model, identifying non-point sources that contribute to stormwater, and determining appropriate reference conditions. Understanding receiving water impacts included projects such as developing bioassessment indicators and protocols, developing microbial source tracking techniques, and evaluating indicators of peak flow impacts. The final report entitled "Stormwater

Research Needs in Southern California” can be found online at ftp://ftp.sccwrp.org/pub/download/PDFs/358_stormwater_workplan.pdf

Develop standardized sampling and analysis protocols (Status: initiated and ongoing)

This project is an attempt to build a stormwater monitoring infrastructure in order to increase comparability among programs throughout southern California. The SMC developed a four-step approach to accomplish this goal: (1) define the monitoring questions of interest, (2) assess what monitoring programs are currently doing to determine how well they are answering the monitoring questions, (3) create an optimum design for answering the monitoring questions, and (4) conduct QA intercalibration studies. This study is partially funded by the State Water Resources Control Board (SWRCB) in response to SB 72, whose legislative goal was to standardize sampling, analysis and reporting for stormwater monitoring. It has been made clear that the SMC is only developing a design for the southern California region.

There has been substantial progress thus far. A technical working group has been formed to guide the study and includes the stormwater agencies and regulators on the SMC, the SWRCB, and at least one environmental group. The group has had one meeting and has begun defining the monitoring questions of interest (step 1). The SMC is currently recruiting a facilitator to continue this process. A laboratory intercalibration is in its initial stages will be completed in the upcoming year.

Microbial Source Tracking Method Comparison (status: initiated and ongoing)

There are numerous waterbodies throughout southern California, both marine and freshwater, that suffer contamination of fecal indicator bacteria such as total coliforms, fecal coliforms, and *enterococcus*. There are several Microbial Source Tracking (MST) techniques now being developed for determining sources (i.e. humans, dogs, cats, horses, etc.) of fecal indicator bacteria in receiving waters. However, all of them are in the early stages of development and none have been tested side-by-side for their ability to accurately discriminate or quantify these sources of fecal contamination. This study was designed to evaluate each of these new methods for accuracy and precision, using bacterial sources from southern California, and then make recommendations to the management community on the most effective and efficient method application(s). The SMC is partially funding this study in collaboration with the US Environmental Protection Agency, State Water Resources Control Board, City of Santa Barbara, and the National Water Research Institute.

Twenty-one of the most prominent researchers in the field are testing nine different MST techniques all at the same time on the same split samples. These techniques include techniques such as ribotyping, antibiotic resistance (ARA), pulsed-field gel

electrophoresis (PFGE), polymerase chain reaction (PCR), and terminal restriction fragment length polymorphism (TRFLP). Each of the specific sources were collected in October and shipped to the researchers for characterization. Next, each sample was added to sterile freshwater or seawater in varying mixtures and densities, then were delivered blind to each laboratory. Each researcher will be asked three questions regarding the blind samples: 1) are human or non-human sources of indicator bacteria are present? 2) if non-human sources are present, what source are they (i.e., dog, cow, seagull)? and 3) what fraction of the sample is attributable to each source? Sample analysis is currently underway and results are expected by February 2003.

Peak Flow Impacts (status: initiated)

Watershed development increases imperviousness eventually leading to alterations in runoff flow regimes. This alteration in flow regime, particularly increased flows during high frequency events (i.e. 1-2 year storms), can result in downstream impacts such as increased erosion or habitat loss. The goal of this study is to quantify impacts from increased peak flows as a result of watershed development. Ultimately, the objective of this study is to develop indicators of peak flow and resulting peak flow impacts so that regulators and regulated agencies can develop numerical criteria for peak flow. This project is fully funded by the Los Angeles County Department of Public Works (LACDPW), although all of the SMC members are interested in this study.

This project is in its initial stages. A Request for Proposals (RFP) was released, written proposals were submitted, and short-listed bidders have had an oral interview. The SMC selection committee is in the process of selecting the winning bidder.

ATTACHMENT 57

ANNUAL REPORT 2008-2009

**Stormwater Monitoring Coalition
Of Southern California**

October 5, 2009

INTRODUCTION

As a result of the increasing regulatory focus and the lack of scientific knowledge base, both stormwater regulators and municipal stormwater management agencies throughout southern California have developed a collaborative working relationship. The goal of this relationship is to develop the technical information necessary to better understand stormwater mechanisms and impacts, and then develop the tools that will effectively and efficiently improve stormwater decision-making. As individuals and agency representatives, there was early recognition that these issues are oftentimes not localized, but typically cross watershed and jurisdictional boundaries. This relationship culminated in a formal letter of agreement, signed in 2000, by all of the Phase I municipal stormwater NPDES lead permittees and the NPDES regulatory agencies in southern California to create the Stormwater Monitoring Coalition (SMC) (Table 1).

Table 1. List of member agencies in the Stormwater Monitoring Coalition.

California Regional Water Quality Control Board, Los Angeles Region
 California Regional Water Quality Control Board, San Diego Region
 California Regional Water Quality Control Board, Santa Ana Region
 California Department of Transportation, Caltrans
 City of Long Beach
 City of Los Angeles, Watershed Protection Division
 County of Orange, Public Facilities and Resources Dept.
 County of San Diego Stormwater Management Program
 Los Angeles County Department of Public Works
 Riverside County Flood Control and Water Conservation District
 San Bernardino County Flood Control District
 Southern California Coastal Water Research Project
 State Water Resources Control Board
 US Environmental Protection Agency, Office of Research and Development
 Ventura County Watershed Protection District

The first project supported by the SMC was to develop a five-year Research Agenda. The research agenda, published in 2001, consisted of 15 unique projects that the SMC ranked, prioritized, and then funded on a voluntary basis. The SMC has made tremendous progress implementing the Research Agenda. Ten of the 15 projects have been started and virtually all have been completed.

The value of the SMC to its member agencies is at least four-fold. The first is the ability to share costs for implementing projects. Cost reductions for SMC member agencies can be significant since collaborative projects can reduce costs by more than 90% relative to footing the bill alone. In addition, the majority of projects have nonmember agency cost-matching. Just for the projects described in this report, there has been nearly one million dollars in grant awards, cost-match, or in-kind services. The second value to member agencies is the ability to stretch their agency's skill base. Stormwater management requires a wide variety of knowledge including regulatory policy, engineering, hydrology, biology, chemistry, toxicity, and microbiology, to name a few. Many member

agencies have limited staff and, by working together, garner the additional skills that are not sustainable within each agency. A third asset of membership is the ability to communicate. Discussions among member agencies provide context and a richness of ideas for application to local issues back home. Similarly, discussion between regulatory and regulated agencies in an informal setting leads to more effective implementation of management activities. Finally, projects conducted under the SMC umbrella have nearly always resulted in some management action. Often, it is difficult for a single agency to affect the current course of regulatory management. Because SMC projects are initiated and vetted through all of the regulated and regulatory management agencies, the results are adopted quickly into the management framework including alterations to NPDES permits.

The SMC has been expanding its role beyond just technical projects by emphasizing outreach and communication. This has occurred through three main venues. The first venue is the establishment of an SMC web site [www.socalsmc.org]. The goal of this web site is to showcase the SMC, but to also provide an outlet for each of the products developed by the agency. The second venue is through the development of project specific Technical Advisory Committees and Working Groups. These Committees are valuable for involving outside experts, but also for including technical staff of the individual agencies. The third venue for outreach is through training and workshops. These have initiated as a result of project specific needs such as LID technology for City Planners or the Hydromodification Workshop associated with CASQA Annual Meetings.

The SMC research should be dynamic and is responding to new issues as they arise. For example, the SMC has reacted to important issues such as evolving Low Impact Development technology, new hydromodification permit requirements, and response to catastrophic events such as wildfires.

PROJECT ACCOMPLISHMENTS

Post-fire monitoring plan

Status: Complete

Estimated Budget: \$75,000

Periodic wildfires are a natural component of southern California's forest and scrubland and essential to maintaining overall ecological health of these systems. However, the frequency and intensity of wildfires has increased in association with human activities in and near natural forest and foothill areas. The effects of fire on hydrologic response and sediment loads in southern California have been noted for over 80 years, yet no coordinated monitoring of water quality following fires currently occurs. The lack of coordinated monitoring is particularly problematic in southern California because watersheds affected by fire often drain to waterbodies that support sensitive resources or that have been designated as impaired under Section 303(d) of the Clean Water Act, often for the same constituents found in post-fire runoff. Consequently, the contribution of

metals, nutrients, and organic contaminants from post-fire runoff to receiving waters is poorly understood in terms of both the magnitude and persistence of potential effects.

The lack of a coordinated post-fire monitoring program results from several factors. First, there is no procedure for post-fire water quality monitoring that identifies a standard set of constituents and monitoring protocols appropriate for assessing water quality following fires. Second, resources are often scarce following fires making it difficult for various entities to coordinate. Third, there is no regional entity responsible for coordinating post-fire sampling, compiling the resultant data, and disseminating the information back to managers at the local and regional levels. Fourth, because fires occur unexpectedly, there is often insufficient available funding for conducting post-fire sampling. This document describes a regional post-fire water quality monitoring program. The goal of the program is to help address the current information gaps by providing agreed upon regional post-fire water quality sampling procedures, including an implementation plan and a funding strategy. This plan was developed by a team of technical experts, stormwater managers, and regulators from academia, government, and the private sector. The plan provides a ready “off-the-shelf” response plan that can be quickly implemented after fires.

The post-fire monitoring program is organized around three priority management questions:

1. How does post-fire runoff affect contaminant flux?
2. What is the effect of post-fire runoff on downstream receiving waters?
3. What are the factors that influence how long post-fire runoff effects persist?

Although they are related, monitoring to address each of the questions is not interdependent. The three major monitoring elements are separable and can be implemented as distinct units or as an integrated program.

A Conceptual Workplan was generated from the workshop participants entitled “Effects of post-fire runoff on surface water quality: Development of a southern California regional monitoring program with management questions and implementation recommendations”

ftp://ftp.sccwrp.org/pub/download/DOCUMENTS/TechnicalReports/598_SoCalRegionalFireMonitoringPlan.pdf.

The regional plan captures sampling design, site selection process, sampling approach, and recommended indicators for each of the monitoring questions. The regional plan includes site selection criteria that allow for pre-selection and prioritization of potential sampling sites based on the sensitivity of potentially affected resources, presence of previous and available monitoring data, feasibility, accessibility, and ability to coordinate with other monitoring programs. Pre-selection of sites and up-front coordination will allow for more rapid and effective response following fires. Finally, the plan includes preliminary recommendations for quality assurance procedures, data management, and communication that will facilitate information sharing and ongoing coordination.

Ongoing program development and coordination will be accomplished through a post-fire runoff working group that consists of the U.S. Forest Service, U.S. Geological Survey,

CAL FIRE, the regional water quality control boards, major municipalities, key landowners, and local researchers. The working group is currently investigating monitoring sites for the Morris, Station and Cottonwood fires.

Stormwater Data Compilation Study

Status: 90% complete

Project Budget: \$75,000 (Resources provided by SCCWRP)

Assessment and prioritization for mitigating water quality requires context. Knowledge of mean concentrations across watersheds, counties, and regulatory jurisdictions provides the perspective needed for managers to rank waterbodies for management action. Regional reference condition, frequency of water quality objective exceedences, extent and distribution of parameter concentrations all play a part in determining where a manager's worst problem occur.

To help managers gain the necessary perspective, the SMC described a project in their Research Agenda that compiles water quality monitoring information regionwide. For several years, the SMC has been building the necessary infrastructure to support such an effort. Data sharing protocols, interlaboratory calibrations, and web-enabled interfaces all enhance the SMC's ability to share data. The goal of this project is to compile the existing water quality monitoring information. Initially starting with nutrients, the objective will be to make annual estimates of concentrations and mass emissions from xx watersheds between Ventura and San Diego.

Remarkable progress was made this year. More than 500,000 data records were compiled among all SMC agencies. Initial assessments indicated that there was tremendous variation and completeness among the data submittals. However, the greatest hindrance towards achieving our goal was not the lack of concentration data, but the lack of flow data. Ultimately, this impacted the ability to estimate annual loads. The data set is currently being augmented with the missing data prior to final load estimates. SCCWRP staff is working with SMC agencies to update data submittal procedures for the 2009-2010 storm season and address remaining issues to improve load estimation.

Implementing A Regionally Consistent and Integrated Freshwater Stream Bioassessment Monitoring Program

Status: 50% complete

Project budget: \$150,000 (\$75,000 contract from the SWRCB)

Assessment of freshwater biological communities represents a potentially powerful tool for evaluating the effects of discharges in southern California creeks and streams. Bioassessments integrate the effects of multiple stressors, including chemical pollutants and physical alterations in receiving waters. The value of biological assessments is that they are closer to many of the defined beneficial uses of receiving waters (i.e. aquatic life, warm water habitat, cold water habitat) than chemically-derived water quality objectives.

As a result, virtually every SMC member agency has biological community monitoring in their respective NPDES permits.

The goal of this study is to implement a coordinated, integrated regional bioassessment monitoring program. Previously, the SMC had worked together to design an optimal monitoring program that satisfied both local needs, but simultaneously provided information that could be combined to make regionwide assessments. Monitoring questions included: 1) What is the extent of impact in streams of southern California? 2) What are the stressors that impact southern California streams? and 3) Is the extent of stream impacts changing over time? Over the last year, over 110 sites were sampled between Ventura and San Diego counties for biological communities, water quality, physical habitat, and riparian condition. Laboratory analysis is currently underway.

While the monitoring information will be extremely useful for assessing cumulative impacts and regional reference condition, a number of useful products have already been achieved. One example is the creation of the Project Quality Assurance Plan (QAPP). To date, the State did not have a QAPP for analysis of biological samples. The SMC working group embraced this challenge and the SWRCB now uses the data quality objectives we established as their standard statewide. Other examples include refined GIS layers of stream networks, staff training for sampling, and field audits to ensure high levels of quality. These milestones translate into not just a high quality regional monitoring program, but rolls over into the ongoing local monitoring programs of each member agency.

Our main collaborator on this project is the California Department of Fish and Game (CDF&G) and SWRCB. The project is 50% funded by the SWRCB, whose main desire is to ensure integration with the Surface Water Ambient Monitoring Program (SWAMP). This will provide further value to SMC member agencies.

Laboratory Intercalibration Study

Status: 90% complete

Project budget: \$17,000 (in-kind services from all participating laboratories)

One goal of the southern California Stormwater Monitoring Coalition (SMC) is to compile monitoring data from separate monitoring programs to make regionwide assessments. For example, the SMC is participating in Regional Monitoring and Regional Data Compilation studies (see previous studies). Both of these studies require not only high quality data, but comparability among laboratories. Despite all SMC laboratories being State-certified, previous intercalibration studies have demonstrated interlaboratory coefficients of variation in excess of 100% for many constituents. As a result, the SMC has endorsed laboratory intercalibration studies based on the types of samples for which they are responsible.

Two laboratory intercalibrations have been conducted by the SMC. The first involved 11 analytical laboratories and focused on suspended solids (TSS), nutrients, and trace metals. The first intercalibration distributed samples to each laboratory blind and in

triplicate, thus assessing both within and between lab variations. Multiple iterations were required for some constituents, but the variability between laboratories was reduced to within laboratory variance ($\leq 20\%$) for most constituents. The end result was a performance-based Guidance Manual that defines the sensitivity, accuracy, and precision necessary for analyzing samples for any SMC member agency
ftp://ftp.secwpr.org/pub/download/PDFs/420_smc_chem.pdf.

The second laboratory intercalibration three years later focused on the same constituents and most of the same laboratories. Interestingly, the range of variability achieved in the previous intercalibration was repeated during the first iteration; a good sign for member agencies indicating that quality assurance was maintained between intercalibrations. A revised Guidance Manual was produced including a scoring system that defined letter grades for intercalibration performance. The SMC began using this laboratory intercalibration as a screening tool for selecting contractors.

The two laboratory Guidance Manual and intercalibration efforts, however, were incomplete in two areas. The first area was the need to repeat the intercalibration periodically as new laboratories, or new personnel at existing laboratories, come along. The second area was the need to intercalibrate on additional constituents. While the original laboratory calibration focused on TSS, nutrients, and trace metals, trace level organic constituents were not included.

The goal of this project is to fill in the missing information to make the Laboratory Guidance Manual an ongoing and effective document. It will involve four steps: 1) recruiting laboratories; 2) repeating the laboratory intercalibration for TSS, nutrients, and trace metals; 3) initiate an intercalibration for organic constituents; and 4) revise and update the Laboratory Guidance Manual. A technical Working Group consisting mostly of laboratory managers has been formed to assist in the study.

The SMC has successfully finished the first three tasks of the study. Fifteen laboratories participated in this intercalibration study; increasing the number of participants by nearly 40%. The intercalibration of TSS, nutrients, and trace metals was based on certified reference materials, a dry weather runoff sample, and a wet weather runoff sample from an urban land use. A longer list of nutrients and metals were added to mimic the list being analyzed for the regional watershed monitoring program. In addition, a number of the constituent reporting limits were lowered to ensure consistency with the SWRCB's ambient monitoring program. The intercalibration for organics focused on over 50 chlorinated hydrocarbons (CHCs; i.e., DDTs, chlordanes, and PCBs) and eight pyrethroid pesticides (i.e., bifenthrin). CHCs were one focus because of the difficulty in confident low level analysis and implication in TMDLs for each of the RWQCB jurisdictions. Pyrethroid pesticides were selected because of its increasingly wide use in the urban landscape by homeowners. To ensure measureable levels of organic analytes, samples were created by distributing unknown calibration standards or by mixing contaminated sediments into a dry weather runoff sample.

Once again, the laboratories performed well including the new laboratories. Minimum levels of comparability were attained after the first iteration for TSS, nutrients, and trace

metals. Laboratories were able to achieve the lowered detection limits and additional analytes. Laboratories were less successful for the organic analytes. Many organic compounds had coefficients of variation exceeding 300%, which is extreme for samples such as standards. However, each of the laboratories has committed to future iterations to ensure quality and comparability for these problematic organic compounds.

The SMC is pursuing a future interlaboratory calibration agreement to maintain the periodicity of the intercalibration, add further organic constituents (i.e., PAHs), and increase the quality and comparability of toxicity measurements.

Hydromodification Study

Status: 50% complete

Project budget: \$1,137,440 (\$1,137,440 State Prop 50 Grant)

The process of urbanization has the potential to affect stream courses by altering watershed hydrology. Development and redevelopment can increase the amount of impervious surfaces on formerly undeveloped landscapes. This reduces the capacity of remaining pervious surfaces to capture and infiltrate rainfall and, as a result, a larger percentage of rainfall becomes runoff during any given storm. In addition, runoff reaches the stream channel much more efficiently, so peak discharge rates post-development are higher compared to predevelopment for an equivalent rainfall event. This process has been termed hydromodification.

Hydromodification can result in adverse effects to stream habitat, surface water quality, and water supply. The stream erosion that results from the increased peak flow can threaten infrastructure, homes, and businesses. Intermittent and ephemeral streams that possess riparian and wetland habitat are at particular risk from effects of hydromodification. Streams in semi-arid regions are especially vulnerable to urbanization due to a prevalence of sand bed channels, lack of vegetative reinforcement, and relatively large net changes in water and sediment supply associated with stormwater runoff. Recent studies by the SMC have indicated that intermittent and ephemeral streams in southern California degrade at lower levels of watershed urbanization than streams in the eastern US.

In response to the effects of hydromodification, state and local agencies are developing standards and management approaches to control and/or mitigate the effects of hydromodification on natural and semi-natural stream courses. Successful implementation of these regulatory programs requires development of tools to better assess hydromodification effects and develop appropriate mitigation and management strategies.

The goal of this project is to develop a series of tools supporting implementation of hydromodification management measures that could be used to better protect the physical, chemical, and biological integrity of streams and their associated beneficial uses. This project will provide tools to answer the following questions: 1) Which streams

are at the greatest risk from the effects of hydromodification? 2) What are the anticipated effects in terms of increased erosion, sedimentation, or habitat loss, associated with increases in impervious cover? 3) What are some potential management measures that could be implemented to offset hydromodification effects and how effective are they likely to be?

This project is being conducted in collaboration with researchers from Colorado State University, Fort Collins. Several milestones have been reached over the previous year. First we completed a review of mapping and classification literature that will serve as the foundation for the classification system developed by this project

ftp://ftp.sccwrp.org/pub/download/PDFs/562_Hydromod_LitReview.pdf. Second, we completed an extensive field campaign that has resulted in a database containing detailed information on channel condition, hydraulics, sedimentary characteristics and other attributes of over 30 stream segments across a gradient of urbanization and landscape settings. Drainage basins have been delineated for all sites and we have quantified several essential watershed metrics for each stream (e.g. watershed area, % impervious, annual rainfall, % burned within last few years, and NRCS soil types vs. rock). Several tools were developed to support processing of the field data, including automated spreadsheets for combining sieve and pebble count sediment samples, as well as for performing numerous hydraulic analyses and generating stream stability metrics. We have also made progress in developing tools for classification and extrapolation flow duration curves from gaged to ungaged sites in regional hydrologic analyses and have populated a database with pre-development flood estimates for each field site.

Over the past year, we have completed a draft hierarchical, multi-scale screening tool for assessing relative risk of stream reaches to the effects of hydromodification. The screening tool includes office/GIS and field assessment levels at watershed, valley and reach scales. Based on extensive field reconnaissance we have identified descriptors of the key physical processes influencing channel responses to hydromodification. For the watershed scale component of the screening tool, there has also been progress on developing a simple classification basin types in terms of the spatial arrangement of channel forms and prevalence of relatively susceptible channel segments. Fourth, we have continued work on developing the modeling tools, focusing on two fronts. This tool will undergo field testing, followed by initial “trial application” in early 2010.

Over the past year, we have also continued testing several existing mobile boundary sediment transport models for potential use in developing simplified tools (nomographs/regressions) of probable channel responses to hydromodification. Towards this end, we have identified a range of hydrologic-geomorphic scenarios for testing the models for their applicability to streams in the study region. We have also developed phase diagram/regime relationships based on sediment transport theory to examine their consistency with results from the more complex mobile boundary models in terms of the extent of channel changes initiated by varying degrees of altered water and sediment regimes. Finally, we have taken advantage of several opportunities for outreach and education. Outreach activities over the past quarter included meeting with the Orange County stormwater copermittees, participating with the San Diego County

hydromodification Technical Advisory Committee, attending a meeting on the Stormwater Monitoring Coalitions's LID/hydromodification workgroup, meeting with the Los Angeles Regional Water Quality Control Board and Ventura County on hydromodification management, and participating with the California Association of Stormwater Quality Agencies (CASQA) hydromodification workgroup.

Low Impact Development Study

Status: 70% complete

Project budget: \$1,100,000 (\$500,000 SMC plus \$600,000 State Prop 40 Grant)

The Low Impact Development Guidance (LID) Study is being conducted with funding from the State Water Resource Control Board's Consolidated Grants Program, under the Urban Runoff Program of Proposition 40. A proposal was submitted by the County of San Bernardino on behalf of the SMC for the LID Project known as "LID Guidance and Training for Southern California."

The LID Project will develop a comprehensive program to incorporate LID strategies and techniques into the planning and design of public and private sector projects. The LID Project will develop a model program for localities in California that are interested in adopting LID strategies and techniques. This will include determining the key technical and institutional issues that must be addressed for successful implementation, pilot projects that demonstrate the effectiveness of LID, and training and outreach to help solidify an implementation strategy to ensure large-scale and long-term success.

The grant funded portion of the project is organized into the following funding areas:

1. **Pilot Project Planning and Design.** *Establish design criteria and site selection*
2. **Monitoring.** *Implementation and demonstration of technology*
3. **Outreach and Training.** *Reporting and facilitation of wide-spread programmatic implementation*

The SMC will provide the required 25% matching funds (\$200,000) for the grant funded tasks. These tasks include preparing a literature review, conducting a series of training workshops, and developing a field monitoring program for LID features. The Literature Review has been completed and the final report will be made available through the California Stormwater Quality Association Website and the SMC website when operational.

A Technical Advisory Committee (TAC) has been established and has reviewed the Literature Review, the initial training materials. The TAC will meet as needed to advise the project as it proceeds.

The SMC completed focused on three major milestones thus far. First, the literature review was completed in year 1. The literature review can be found on the SMC web site [www.socalsmc.org]. Second, the SMC supported several training workshops including August 29, 2007 at Inland Empire Utilities Agency in Chino; November 6, 2007 at the

Urban Water Institute in Costa Mesa; and June 6, 2008 at the Metropolitan Water District in Los Angeles. Third, the SMC drafted the Technical Design and Guidance Document. This document captures the essential elements of LID selection, guidance criteria, and implementation recommendations. The Guidance Manual is being prepared in a web-portal format to allow efficient access via the World Wide Web. Fourth, the SMC initiated monitoring of LID technology. One site has is being monitored in Irvine and several others are in preparation to be monitored in Los Angeles, Riverside (Riverside County Flood Control and Water Conservation District pilot LID testing facility), and Rancho Cucamonga.

Work on this project was reduced from December 2008 to June 2009 due to State's freeze on all Proposition 40 Grant projects. The SMC and the County of San Diego provided bridge funding to ensure cost-effective opportunities are not lost, but completion of project milestones has been delayed. The web-based Guidance Manual is expected to be completed by the end of 2009.

ATTACHMENT 58

ANNUAL REPORT 2010-2011

**Stormwater Monitoring Coalition
Of Southern California**

DRAFT - September 30, 2011

INTRODUCTION

As a result of the increasing regulatory focus and the lack of scientific knowledge base, both stormwater regulators and municipal stormwater management agencies throughout southern California have developed a collaborative working relationship. The goal of this relationship is to develop the technical information necessary to better understand stormwater mechanisms and impacts, and then develop the tools that will effectively and efficiently improve stormwater decision-making. As individuals and agency representatives, there was early recognition that these issues are oftentimes not localized, but typically cross watershed and jurisdictional boundaries. This relationship culminated in a formal letter of agreement, signed in 2000 and again in 2009, by all of the Phase I municipal stormwater NPDES lead permittees and the NPDES regulatory agencies in southern California to create the Stormwater Monitoring Coalition (SMC) (Table 1).

Table 1. List of member agencies in the Stormwater Monitoring Coalition.

California Regional Water Quality Control Board, Los Angeles Region
 California Regional Water Quality Control Board, San Diego Region
 California Regional Water Quality Control Board, Santa Ana Region
 California Department of Transportation, Caltrans
 City of Long Beach
 City of Los Angeles, Watershed Protection Division
 County of Orange, Public Facilities and Resources Dept.
 County of San Diego Stormwater Management Program
 Los Angeles County Department of Public Works
 Riverside County Flood Control and Water Conservation District
 San Bernardino County Flood Control District
 Southern California Coastal Water Research Project
 State Water Resources Control Board
 US Environmental Protection Agency, Office of Research and Development
 Ventura County Watershed Protection District

The first project supported by the SMC was to develop a five-year Research Agenda. The research agenda, published in 2001, consisted of 15 unique projects that the SMC ranked, prioritized, and then funded on a voluntary basis. The SMC has made tremendous progress implementing the Research Agenda. To date, over a dozen projects have been implemented by the SMC.

The value of the SMC to its member agencies is at least four-fold. The first is the ability to share costs for implementing projects. Cost reductions for SMC member agencies can be significant since collaborative projects can reduce costs by more than 90% relative to footing the bill alone. In addition, the majority of projects have nonmember agency cost-matching. Just for the projects described in this report, there has been nearly one million dollars in grant awards, cost-match, or in-kind services. The second value to member agencies is the ability to stretch their agency's skill base. Stormwater management requires a wide variety of knowledge including regulatory policy, engineering, hydrology, biology, chemistry, toxicity, and microbiology, to name a few. Many member

agencies have limited staff and, by working together, garner the additional skills that are not sustainable within each agency. A third asset of membership is the ability to communicate. Discussions among member agencies provide context and a richness of ideas for application to local issues back home. Similarly, discussion between regulatory and regulated agencies in an informal setting leads to more effective implementation of management activities. Finally, projects conducted under the SMC umbrella have nearly always resulted in some management action. Often, it is difficult for a single agency to affect the current course of regulatory management. Because SMC projects are initiated and vetted through all of the regulated and regulatory management agencies, the results are adopted quickly into the management framework including alterations to NPDES permits.

The SMC has shown tremendous growth over the last 10 years. The SMC has faced and overcome several potential stumbling blocks such as project funding mechanisms, turnover of member agency staff, identifying and implementing outreach and communication activities, and invigorating new project leadership. The SMC now faces a new set of challenges for the year to come. Most significant of these is the ability to identify and implement a new research agenda. The technical complexities facing stormwater managers and the ever-expanding regulatory framework in which they interact seems enormous. The new research agenda should help identify, clarify, and prioritize the direction of the SMC for the next phase of its existence. A second test of the SMC's growing pains is its ability to adapt and evolve. For example, initiating and authorizing new project agreements now takes over two years. This is insufficient for an organization that wants to be adaptive and respond to opportunities.

PROJECT ACCOMPLISHMENTS

Stormwater Data Compilation Study

Status: 90% complete

Initial Project Budget: \$75,000 (Resources provided by SCCWRP)

Amended Project Budget: \$110,000 (Resources provided by SCCWRP)

Assessment and prioritization for mitigating water quality requires context. Knowledge of mean concentrations across watersheds, counties, and regulatory jurisdictions provides the perspective needed for managers to rank waterbodies for management action. Regional reference condition, frequency of water quality objective exceedences, extent and distribution of parameter concentrations all play a part in determining where a manager's worst problem occur.

To help managers gain the necessary perspective, the SMC described a project in their Research Agenda that compiles water quality monitoring information regionwide. For several years, the SMC has been building the necessary infrastructure to support such an effort. Data sharing protocols, interlaboratory calibrations, and web-enabled interfaces all enhance the SMC's ability to share data. The goal of this project is to compile the existing water quality monitoring information. Initially starting with nutrients, the

objective will be to make annual estimates of concentrations and mass emissions from 25 watersheds between Ventura and San Diego.

To date, more than 600,000 data records have been compiled among all SMC agencies. Initial assessments indicated that there was tremendous variation and completeness among the data submittals. However, the greatest hindrance towards achieving our goal was not the lack of concentration data, but the lack of flow data. Ultimately, this impacted the ability to estimate annual loads. The data set is currently being augmented with modeling based information to compile final load estimates.

Implementing A Regionally Consistent and Integrated Freshwater Stream Bioassessment Monitoring Program

Status: 75% complete

Project budget: \$150,000 (\$75,000 contract from the SWRCB)

Assessment of freshwater biological communities represents a potentially powerful tool for evaluating the effects of discharges in southern California creeks and streams. Bioassessments integrate the effects of multiple stressors, including chemical pollutants and physical alterations in receiving waters. The value of biological assessments is that they are closer to many of the defined beneficial uses of receiving waters (i.e. aquatic life, warm water habitat, cold water habitat) than chemically-derived water quality objectives. As a result, virtually every SMC member agency has biological community monitoring in their respective NPDES permits.

The goal of this study is to implement a coordinated, integrated regional bioassessment monitoring program. Previously, the SMC had worked together to design an optimal monitoring program that satisfied both local needs, but simultaneously provided information that could be combined to make regionwide assessments. Monitoring questions included: 1) What is the extent of impact in streams of southern California? 2) What are the stressors that impact southern California streams? and 3) Is the extent of stream impacts changing over time?

This is the third year of a five-year project. In the first year, over 110 sites were sampled between Ventura and San Diego counties for biological communities, water quality, physical habitat, and riparian condition. Preliminary results indicated that roughly 50% of the stream miles in southern California have healthy biological communities. In addition, the extent of chemical contamination appears lower than previously thought. For example, less than 3% of the stream miles exceeded the chronic water quality criterion for copper. Sampling for the third year is now finished and samples are at the laboratory for analysis. The first year report, along with a fact sheet, was published this year.

- RD Mazor, DJ Gillett, K Schiff, K Ritter, E Stein. 2011. [Ecological Condition of Watersheds in Coastal Southern California: Progress Report of the Stormwater Monitoring Coalition's Stream Monitoring Program First Year \(2009\)](#). Technical

Report 639. Prepared for the Stormwater Monitoring Coalition Bioassessment Workgroup. Southern California Coastal Water Research Project. Costa Mesa, CA.

The SMC regional watershed monitoring program is now serving as a model for other parts of the state. Regional watershed programs in the San Francisco Bay and the Central Valley are planning to use the SMC as a model for their design and implementation. Perhaps the biggest value of the SMC regional watershed monitoring, however, is its connection to the SWRCB's development of biological objectives. This new policy will set narrative and numeric limits on biological condition in streams statewide. Because of the unique collaboration in southern California, approximately one-third of the data used to develop the biological objectives will come from the SMC region.

Our main collaborator on this project is the California Department of Fish and Game (CDF&G) and SWRCB. The project is 50% funded by the SWRCB, whose main desire is to ensure integration with the Surface Water Ambient Monitoring Program (SWAMP).

Hydromodification Study

Status: 80% complete

Project budget: \$1,137,440 (State Prop 50 Grant)

The process of urbanization has the potential to affect stream courses by altering watershed hydrology. Development and redevelopment can increase the amount of impervious surfaces on formerly undeveloped landscapes. This reduces the capacity of remaining pervious surfaces to capture and infiltrate rainfall and, as a result, a larger percentage of rainfall becomes runoff during any given storm. In addition, runoff reaches the stream channel much more efficiently, so peak discharge rates post-development are higher compared to predevelopment for an equivalent rainfall event. This process has been termed hydromodification.

Hydromodification can result in adverse effects to stream habitat, surface water quality, and water supply. The stream erosion that results from the increased peak flow can threaten infrastructure, homes, and businesses. Intermittent and ephemeral streams that possess riparian and wetland habitat are at particular risk from effects of hydromodification. Streams in semi-arid regions are especially vulnerable to urbanization due to a prevalence of sand bed channels, lack of vegetative reinforcement, and relatively large net changes in water and sediment supply associated with stormwater runoff. Recent studies by the SMC have indicated that intermittent and ephemeral streams in southern California degrade at lower levels of watershed urbanization than streams in the eastern US.

In response to the effects of hydromodification, state and local agencies are developing standards and management approaches to control and/or mitigate the effects of hydromodification on natural and semi-natural stream courses. Successful implementation of these regulatory programs requires development of tools to better

assess hydromodification effects and develop appropriate mitigation and management strategies.

The goal of this project is to develop a series of tools supporting implementation of hydromodification management measures that could be used to better protect the physical, chemical, and biological integrity of streams and their associated beneficial uses. This project will provide tools to answer the following questions: 1) Which streams are at the greatest risk from the effects of hydromodification? 2) What are the anticipated effects in terms of increased erosion, sedimentation, or habitat loss, associated with increases in impervious cover? 3) What are some potential management measures that could be implemented to offset hydromodification effects and how effective are they likely to be?

This project is being conducted in collaboration with researchers from Colorado State University, Fort Collins. Several major elements have been completed this year. Building off the previously completed literature review and field work, we completed the GIS-based and field-based hydromodification screening tools that can be used to evaluate susceptibility of channels to hydromodification effects. The tools were published in a series of three technical reports:

- Bledsoe B.P, R.J. Hawley, E.D. Stein, D.B. Booth. 2010. [Hydromodification Screening Tools: Technical basis for development of a field screening tool for assessing channel susceptibility to hydromodification](#). Southern California Coastal Water Research Project Technical Report #607.
- Bledsoe B.P, R.J. Hawley, E.D. Stein, D.B. Booth. 2010. [Hydromodification Screening Tools: Field manual for assessing channel susceptibility](#). Southern California Coastal Water Research Project Technical Report #606.
- Booth D.B., S.R. Dusterhoff, E.D. Stein, B.P. Bledsoe. 2010. [Hydromodification Screening Tools: GIS-based catchment analyses of potential changes in runoff and sediment discharge](#). Southern California Coastal Water Research Project Technical Report #605.

Use of these tools has been incorporated into several municipal stormwater permits. Therefore, SCCWRP staff has held training sessions on use of this tool and are working with the water board training academy on establishing an ongoing training program.

Over the past year, we also completed the analysis of forty-three regional U. S. Geological Survey gauges with records greater than ~20 yrs located in watersheds ranging from 1.3 – 272 km² to develop regionally calibrated, empirically derived models that can be used to estimate flow from ungauged streams throughout southern California. These models can be used to supplement the USGS regional regression equations with more local data. Retrospective analysis of these flow gauges also showed that large increases were observed in instantaneous-peak flows of more frequent return periods (e.g., 1.5 and 2 year storms), with greater than a 5-fold increase in 2-year events (Q2) observed in a watershed with 20% imperviousness relative to \leq ~1% imperviousness.

Effects of urbanization decreased for larger, less frequent storms. The results of these analysis are provided in the following technical report:

- Hawley, R.J., B.P. Bledsoe and E.D. Stein 2011. [Hydromodification Effects on Flow Peaks and Durations in Southern California Urbanizing Watersheds](#). Southern California Coastal Water Research Project Technical Report # 654.

Finally, progress was made over the last year on the final two deliverables of this project; guidance on model application and a framework for hydromodification monitoring. Drafts of both documents were developed in coordination with a technical workgroup and will be ready for review in early 2012.

Effects of Wildfires on Contaminant Runoff and Emissions

Status: 85% complete

Project Budget: \$100,000 + in-kind contributions (\$75,000 provided by San Diego County, \$25,000 provided by the Los Angeles Regional Water Quality Control Board, in-kind services provided by UCLA and Los Angeles County Flood Control District)

Fire is a natural component of Mediterranean ecosystems, such as those found in southern California. Due to loss of plant cover, severe burns have been shown to increase runoff and sediment generation to downstream areas. Constituents associated with the increased runoff have the potential to affect water quality in downstream receiving waters and the near-shore coastal environment. This may be especially problematic for streams that are already impaired. Most research on post-fire water quality has focused on nutrient and sediment enrichment in relatively natural areas. However, post-fire runoff also has the potential to increase loadings of carbon, organic compounds such as PAHs, and trace metals. Constituent loadings may occur by several mechanisms over a range of spatial and temporal scales. Potential loading mechanisms include direct runoff, debris flows, or atmospheric deposition of ash followed by storm runoff. Investigating the magnitude and duration of fire effects in downstream and/or adjacent watersheds is critical to accounting for its influence on cumulative water quality impacts and attaining water quality standards.

This goal of this project is to investigate the fate of water quality constituents resulting from southern California wildfires in order to quantify the effects of post-fire runoff on downstream metals and organic constituent concentrations and loads. Contaminant loading and effects on instream biota will be investigated as part of this project.

A regional post-fire monitoring strategy was completed in 2009 that describes an agreed-upon approach for post-fire sampling.

- ED Stein, J Brown. 2009. [Effects of post-fire runoff on surface water quality: Development of a southern California regional monitoring program with management questions and implementation recommendations](#). Technical Report 598. Southern California Coastal Water Research Project. Costa Mesa, CA.

This plan was implemented for the first time following the 2010 Station Fire, which burned portions of the Los Angeles and San Gabriel River watersheds. Two sites were sampled for solids, metals, and PAHs over six storms following the 2010 fires; Tujunga Wash and Arroyo Seco. Results showed dramatic increases in concentrations and loads of all constituents sampled following storms, but returning to near pre-fire levels by the end of the storm season. The results of this analysis have been written up as for submittal a journal and inclusion in this year's SCCWRP Annual Report. Additional analysis of post-fire pollutant concentration data has been compiled for storms dating back to 2003. This data is currently being analyzed for regional patterns and to investigate factors that may influence pollutant loading (e.g. burn intensity, pre-fire vegetation, watershed size). In addition, post-fire bioassessment data from both the 2003 San Diego county fires and the 2009 Los Angeles County Station fire have been compiled and are being analyzed to assess fire effects on benthic indices typically used as part of regional bioassessment monitoring. This analysis will continue over the next year.

Low Impact Development Study

Status: 80% complete

Project budget: \$1,100,000 (\$500,000 SMC plus \$600,000 State Prop 40 Grant)

The Low Impact Development Guidance (LID) Study is being conducted with funding from the State Water Resource Control Board's Consolidated Grants Program, under the Urban Runoff Program of Proposition 40. The LID Project will develop a comprehensive program to incorporate LID strategies and techniques into the planning and design of public and private sector projects. The LID Project will develop a model program for localities in California that are interested in adopting LID strategies and techniques.

This project has been successful in attaining these goals:

- *Develop interim guidance and training for LID implementation.* Four training sessions were held throughout the Southern California region from 2007 through 2008.
- *Determine effectiveness of LID for reduction of pollutant loads and hydrologic changes in Southern California.* Monitoring results were used to assess the volume and concentration benefits to discharges, the percentage of runoff from various BMPs and LID systems measured, and a review of the soil type. There are ongoing LID monitoring programs that will provide additional results regarding the effectiveness of LIDs in Southern California.
- *Develop guidelines on specifications and standards for Project design and review.* The SMC and CASQA finalized the LID Guidance Manual in April 2010. It is now located on the CASQA web site.
- *Develop final guidance and training materials using field data.* This goal was partially met. The San Bernardino Flood Control District and the SMC have developed final guidance and training materials using the feedback from interim trainings, the literature review, and using the final LID Guidance Manual. However, field data collected as part of this project has yet to be incorporated into the LID Guidance Manual.

- *Conduct training workshops in Southern California.* In addition to the interim training workshops, final Training was provided by online web access to the Manual and presentations that provided manual content and access information.

The District coordinated with various regional and statewide efforts that involved LID training, including San Diego County, the California Water and Land Use Partnership, the California Coastal Commission, the Local Government Commission, and the Chino Basin Landscape Alliance. The collaborative regional effort was a critical networking tool that provided additional funding, technical support, and LID monitoring opportunities. Partner agencies included the County of San Diego, Riverside County, and CASQA, all of whom helped support the project when Grant funding was frozen mid-project by the State of California. Approximately \$260,000 has been leveraged for future activities during the 2010-2011 and 2011-2012 fiscal years.

SMC and CASQA plan to continue updating the LID Guidance Manual and provide training sessions. Monitoring is planned to continue through spring of 2012. Monitoring reports are expected to be provided upon completion of data analysis and reporting.

Barriers to Low Impact Development (LID) Study

Status: 40% complete

Project Budget: \$30,750 (\$27,000 County of San Diego, \$1,250 Riverside County Flood Control & Water Conservation District, \$1,250 Ventura County Watershed Protection District, San Bernardino County Flood Control District, \$1,250)

While many communities understand the benefits of low impact development (LID), getting LID projects built has been difficult. In an effort to address the difficulties in LID implementation, the SMC has commissioned the Local Government Commission (LGC) to investigate the barriers its members are facing, and to prioritize strategies to remove those barriers. Of particular interest are external barriers at the state level over which local jurisdictions do not have control.

To date, a literature review focusing on the site design and approval processes and associated codes, processes and perceptions has been completed. Barriers gleaned from the literature review were then compiled and shared with SMC members for review and comment. A comprehensive list of barriers taken from the literature review and from SMC member comments were then incorporated into an online survey that was distributed to local, regional, and state agencies where they were asked to rank the significance of each barrier as it applied to their jurisdiction. Another online survey was created for and distributed to the development community to gather feedback from the private sector. Phone interviews and three small focus groups are set to occur in late October and early November, which will allow a more in-depth investigation of barriers for implementing LID in Southern California.

LGC will generate a report summarizing research process as well as research findings. This report will be presented at SMC's December 2011 meeting where LGC will also receive input from SMC members regarding the key barriers LGC should focus on in Phase II of this project, which is developing strategies for overcoming key barriers. The project will be completed by May 2012.

ATTACHMENT 59

Southern California Stormwater Monitoring Coalition

About SMC

The SMC was formed in 2001 by cooperative agreement of the Phase I municipal stormwater NPDES lead permittees, the NPDES regulatory agencies in southern California and the Southern California Coastal Water Research Project. The SMC has been so successful that the member agencies have renewed the **Cooperative Agreement** for another five years commencing June 2008 and added three new member agencies, the California Department of Transportation, the City of Los Angeles, and the State Water Resources Control Board. The current list of SMC members is as follows:

County of Los Angeles, Department of Public Works

County of Orange, OC Public Works

County of San Diego, Department of Public Works

Riverside County Flood Control and Water Conservation District

San Bernardino County Flood Control District

Ventura County Watershed Protection District

Image result for City of Long Beach Public Works Department
ca

City of Long Beach Public Works Department

City of Los Angeles, Department of Public Works

California Regional Water Quality Control Board, Santa Ana Region

California Regional Water Quality Control Board, Los Angeles Region

California Regional Water Quality Control Board, San Diego Region

State Water Resources Control Board

California Department of Transportation

Southern California Coastal Water Research Project (SCCWRP)

Collaborating Organization

**US Environmental Protection Agency, Office of
Research and Development**

The SMC also has a cooperative **Memorandum of Understanding** with the United States Environmental Protection Agency Office of Research and Development to facilitate the development of scientific and technical tools for stormwater program implementation, assessment, and monitoring.

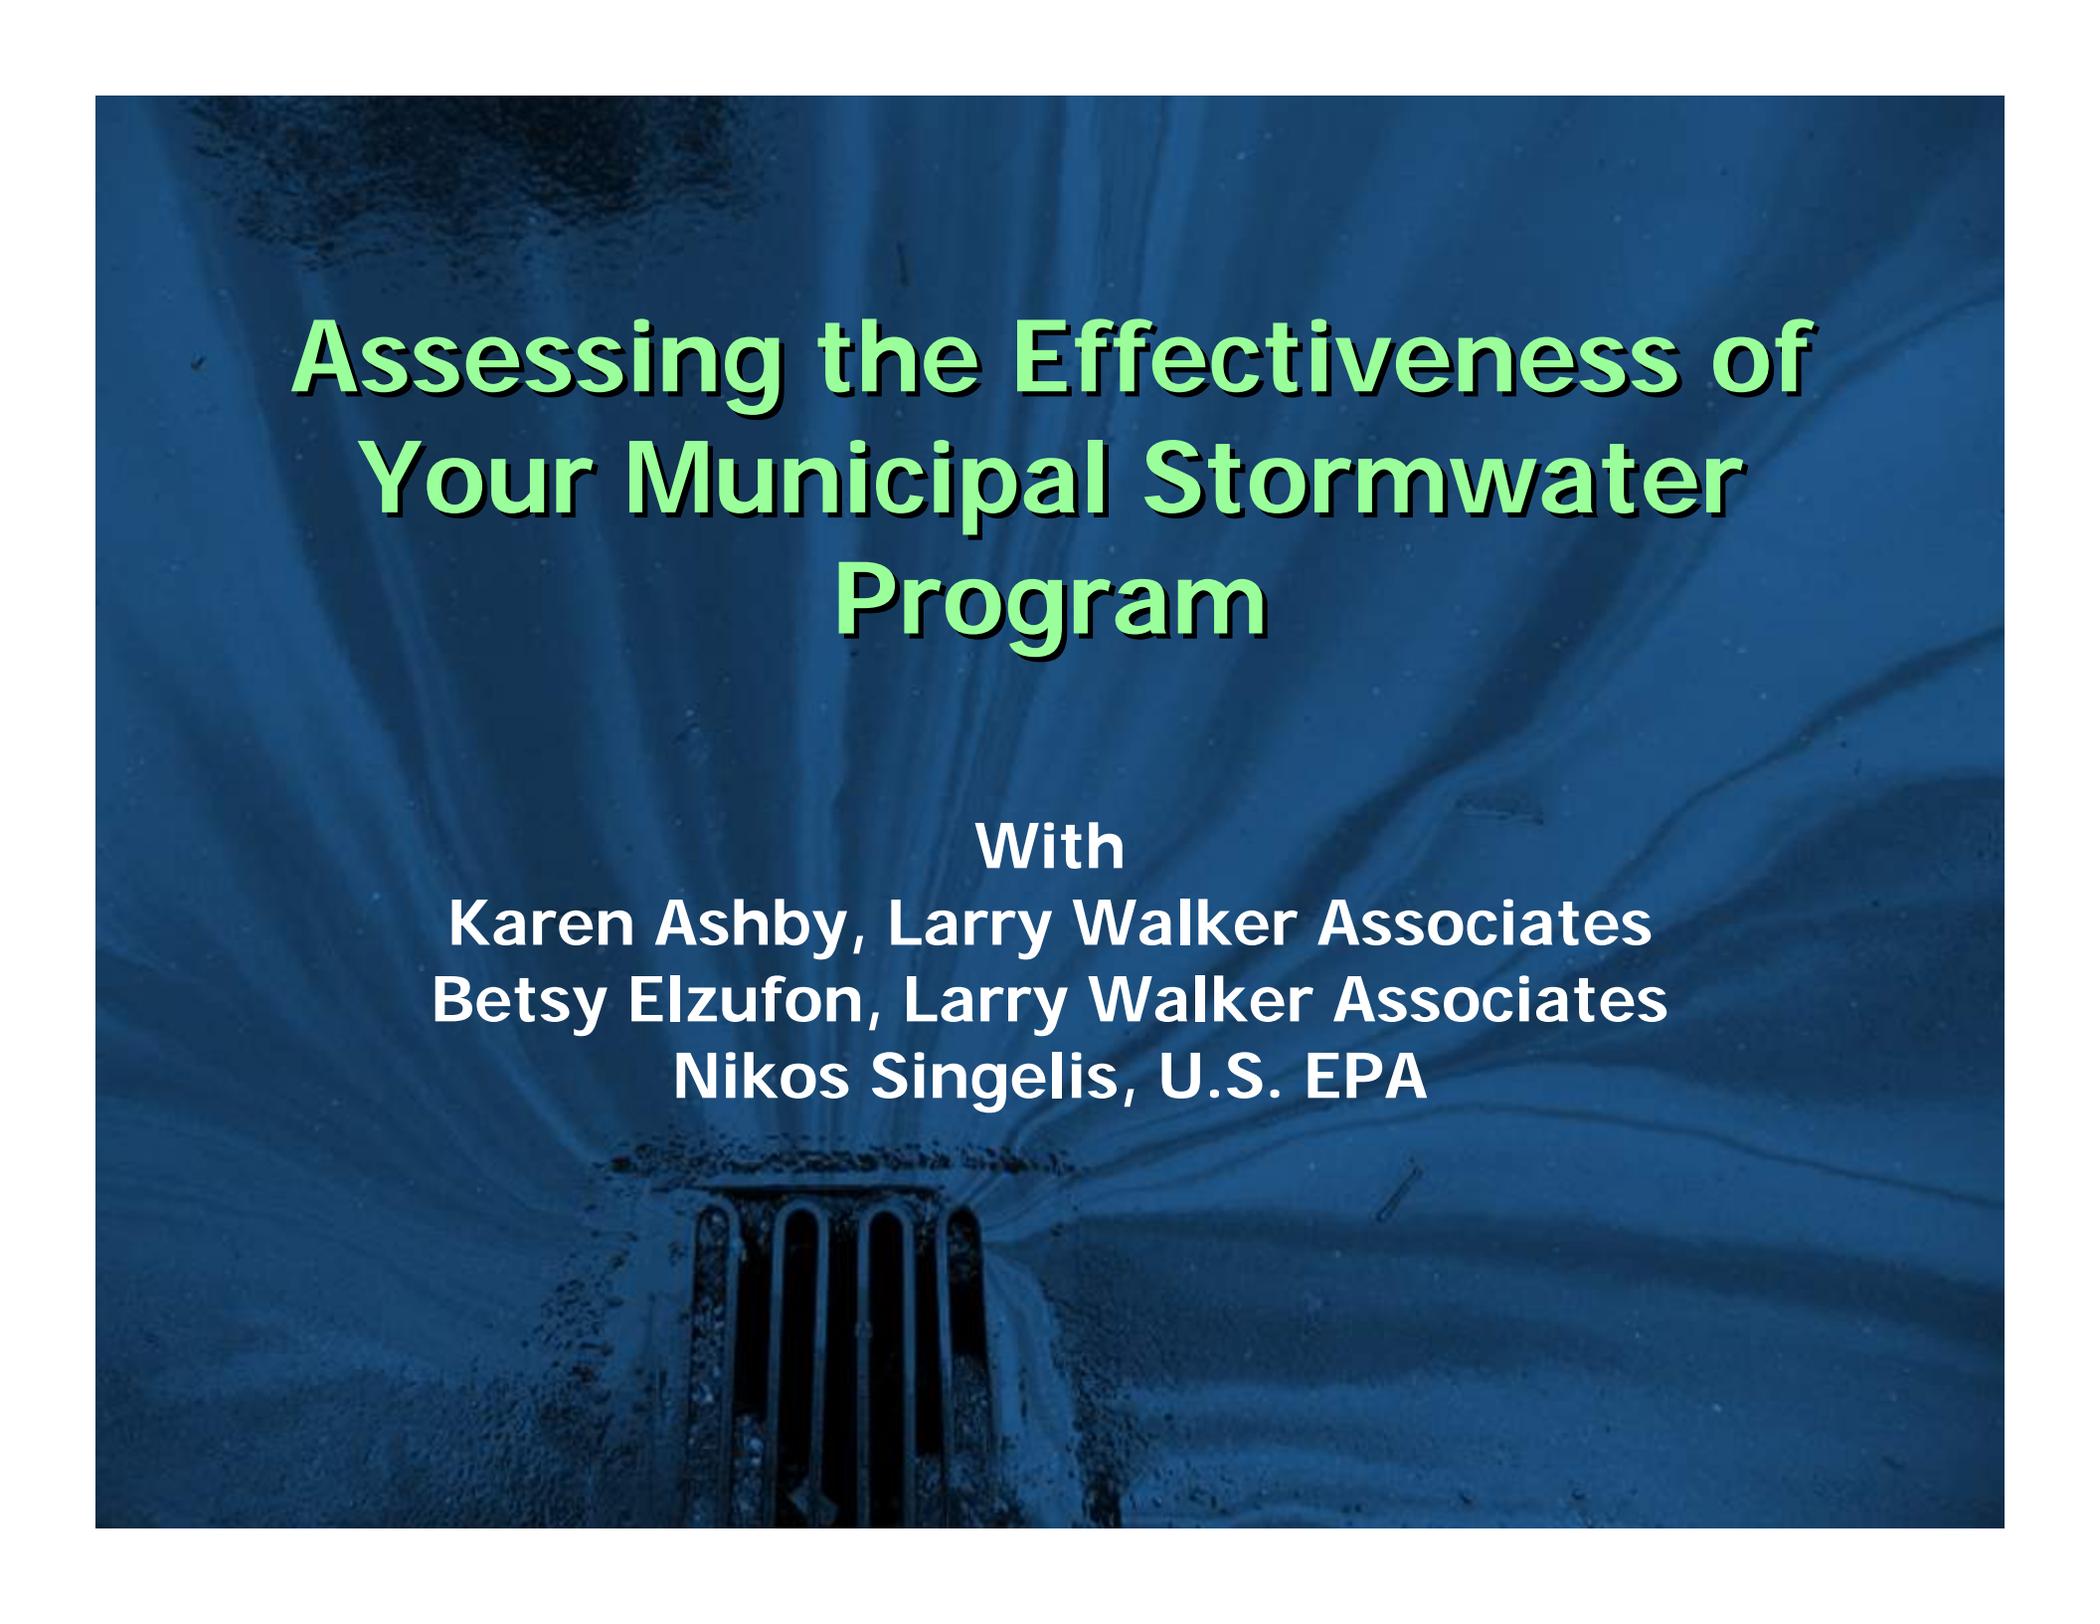

The SMC is managed by Steering Committee of its members that meets quarterly to review new projects and assess progress on ongoing projects.

Assessing the Effectiveness of Your Municipal Stormwater Program

With

Karen Ashby, Larry Walker Associates

Betsy Elzufon, Larry Walker Associates

Nikos Singelis, U.S. EPA

Guide to Our Webcasts

For Technical Support click the "Help" button

- **To Ask a Question** - Type your question in the text box located in the lower left-hand corner of your screen and click on the "Submit Question" button
- **To Answer a Poll Question** – Click on the radio button to the left of your choice and click submit. Do not type your answer in the "Ask a Question" box
- **To See Closed Captioning** – Turn your pop-up blocker off and click on the "closed captioning" button
- **To Complete the Survey** – Turn off your pop-up blocker
- **To Obtain a Certificate** – Watch 1 hour and 30 minutes of the webcast and then click "Download Certificate." If you are in a room with multiple attendees please wait until the last slide to obtain the URL to customize your own certificates

Topics:

- **Planning and Priority Setting for MS4s**
- **Key Elements for Effective Municipal Programs**
- **Measuring and Assessing MS4 Programs**
 - California Stormwater Quality Association (CASQA)
Municipal Stormwater Program Effectiveness Assessment Guidance
- **Municipal Operations/Good Housekeeping Case Study**

Planning and Priority Setting

Know Your Watershed!

- Water Quality Standards/Designated Uses
- Existing impacts (impairments and TMDLs)
- Land uses, current and future
- Social factors
- Regulatory framework
- Drainage and flooding issues

Planning and Prioritizing

Planning Should Occur at Multiple Levels

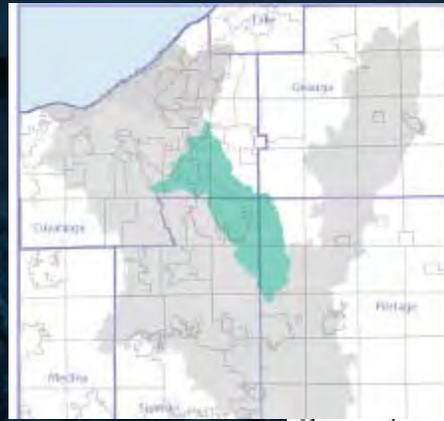

- **Geographic Scales**
 - Local (stream, wetland, etc.)
 - Watershed (river, basin, etc.)
 - Ideally, shared goals and implementation plans with MS4s, watershed organizations, etc.
 - Regional
 - Ideally, shared goals and implementation plans with MS4s, watershed organizations, etc.

Stormwater Management Plan

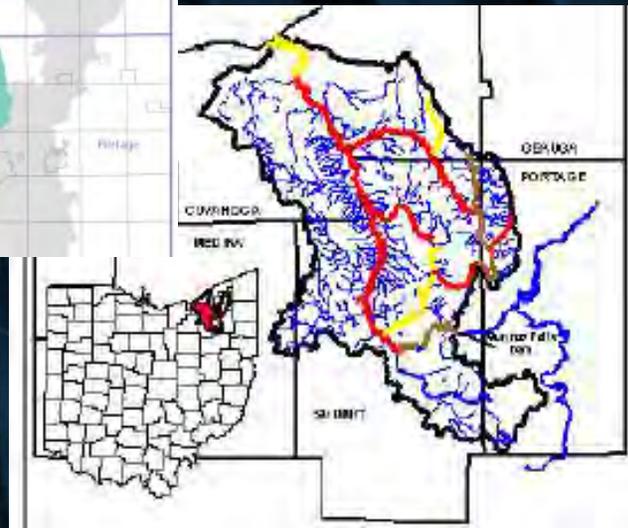

- Local plan will synthesize information from three levels, including:
 - Pollutants
 - Hydrologic/Physical
 - Biological
 - Current and future land use
- Consider sources
- Consider ability to affect change
- Develop a logical set of priorities and measurable goals to frame stormwater management plan

Example: Northeast Ohio

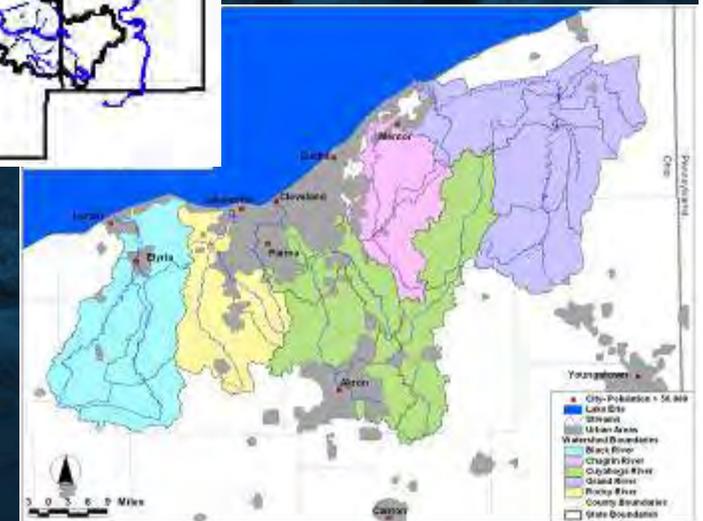

Local:
Tinker's Creek

Watershed:
Cuyahoga
River

Regional: Lake Erie

Possible Priorities for NE Ohio

- **Local (Tinker's Creek)**
 - Organic enrichment/dissolved oxygen
 - Wastewater treatment plants
- **Watershed (Cuyahoga River)**
 - Nitrogen and Phosphorus
 - Urban stormwater, particularly lawn care
 - Bacteria
 - CSOs and Urban Stormwater
- **Regional (Lake Erie)**
 - Phosphorus
 - Agriculture
 - Urban stormwater
 - Bacteria
 - CSOs and Urban Stormwater

MS4 Stormwater Management Program

- Clear and logical priorities
- Measurable Goals
- Detailed action plans

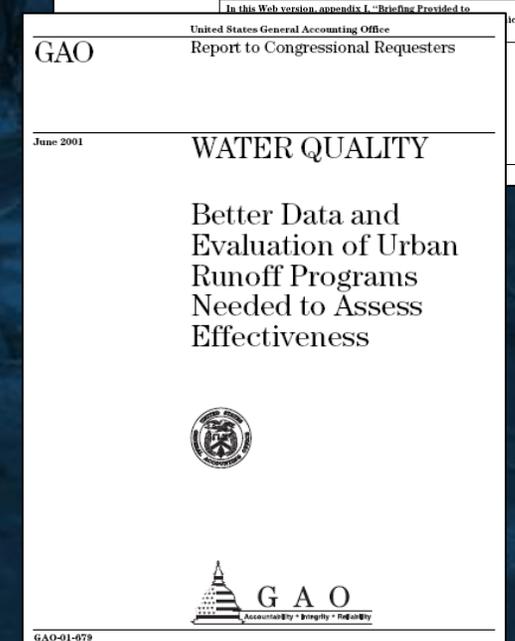

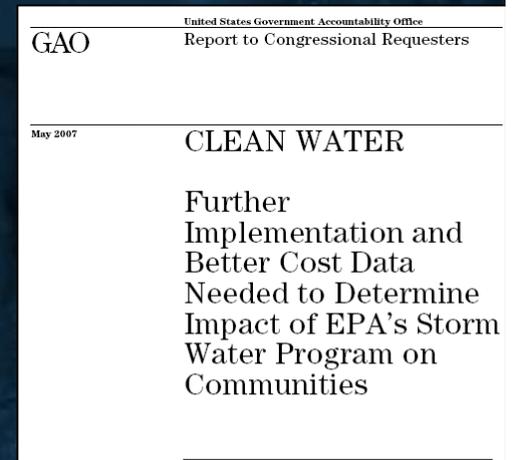

EPA's Compliance Monitoring Strategy

Provides inspection frequency goals for all NPDES program, including stormwater:

- Phase I MS4s – Audit every Phase I MS4 within five years. Inspect as needed.
- Phase II MS4s – Audit and inspect every Phase II MS4 within seven years
- www.epa.gov/compliance/resources/policies/monitoring/cwa/npdescms.pdf

Congress identified the need for better effectiveness information

- GAO found that neither costs nor effectiveness of stormwater program has been determined
- EPA must examine Phase II implementation starting in 2012

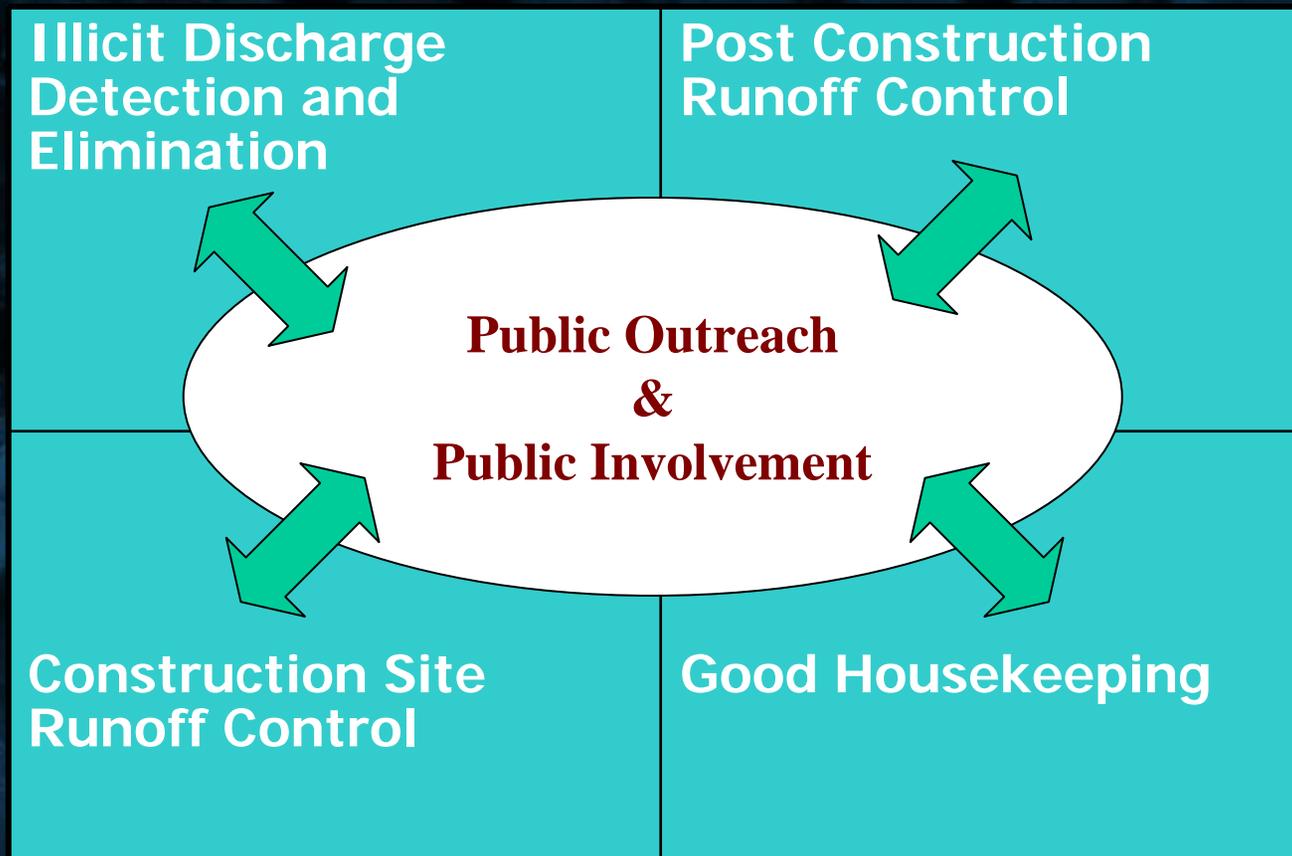

Essential Elements of Successful MS4 Programs

Public Education and Involvement

- EPA's *Getting In Step* manuals for outreach campaigns and stakeholder involvement
- More than just producing brochures!

Public Education & Involvement

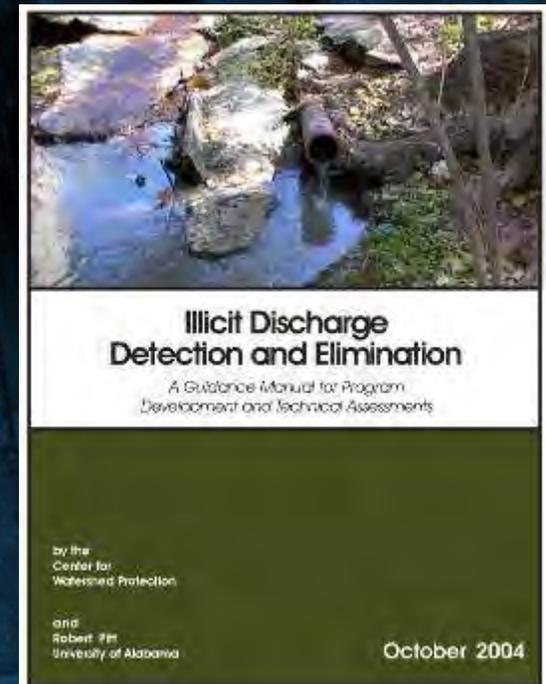

Public Ed. & Involvement Essentials

- Using the *Getting In Step* method:
 - Assessed knowledge and understanding
 - Developed priorities for outreach activities
 - Implemented at least one significant and sustained outreach campaign based on a pollutant of concern and designed to change behaviors
 - Implemented involvement activities, such as citizen's advisory committee, etc.

Eight Steps to Build an IDDE Program

Using the IDDE Manual:

- Audited Existing Resources & Programs
- Established Responsibility, Authority & Tracking
- Completed a Desktop Assessment of Illicit Discharge Potential
- Developed Program Goals & Implementation Strategies
- Searched for Illicit Discharge Problems in the Field
- Isolated & Fix Individual Discharges
- Prevented Illicit Discharges
- Evaluated the Program

IDDE: Key Elements

- **Ordinance**
 - Prohibition on non-stormwater discharges
 - Ability to stop discharges/correct problems
 - Access
 - Fines and Penalties
- **System map**
- **Assessment of sub-watershed potential**
- **Staff trained**
- **Tracking system**
- **Public education, e.g. hotline**
- **Address all obvious, flowing illicit discharges**

Construction Site Management

- Manage runoff from construction sites disturbing 1 or more acres of land, including smaller sites that are part of a larger, common plan of development

Construction: Key Elements

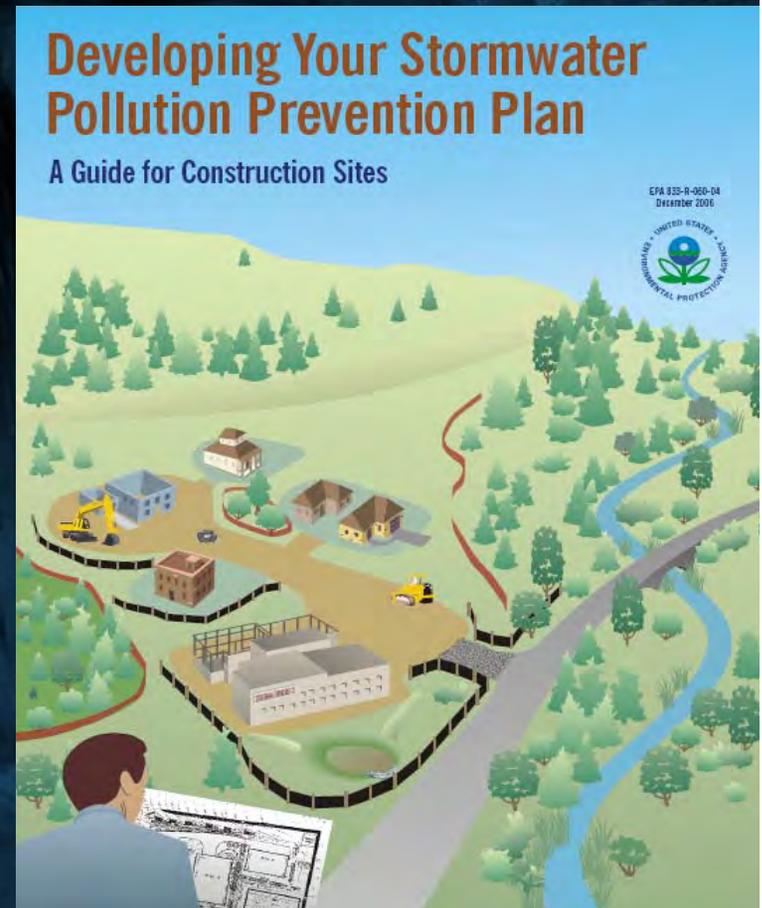

- Ordinance in place
 - Sediment and erosion
 - Good housekeeping/
pollution prevention
 - Submit plans for
review
 - Fines and penalties

Not a SWPPP!

Construction: Key Elements

- **Plan review process**
 - Trained staff
 - Integrated with post-construction review
 - Consider public input
- **Inspection**
 - Inventory and tracking of sites
 - Ability to respond to citizen complaints
 - Schedules, routine vs. targeted
- **Education**
 - Builders and developers, citizens, staff

Post-Construction

- **Develop, implement, and enforce a program to address stormwater runoff from new development and redevelopment projects***

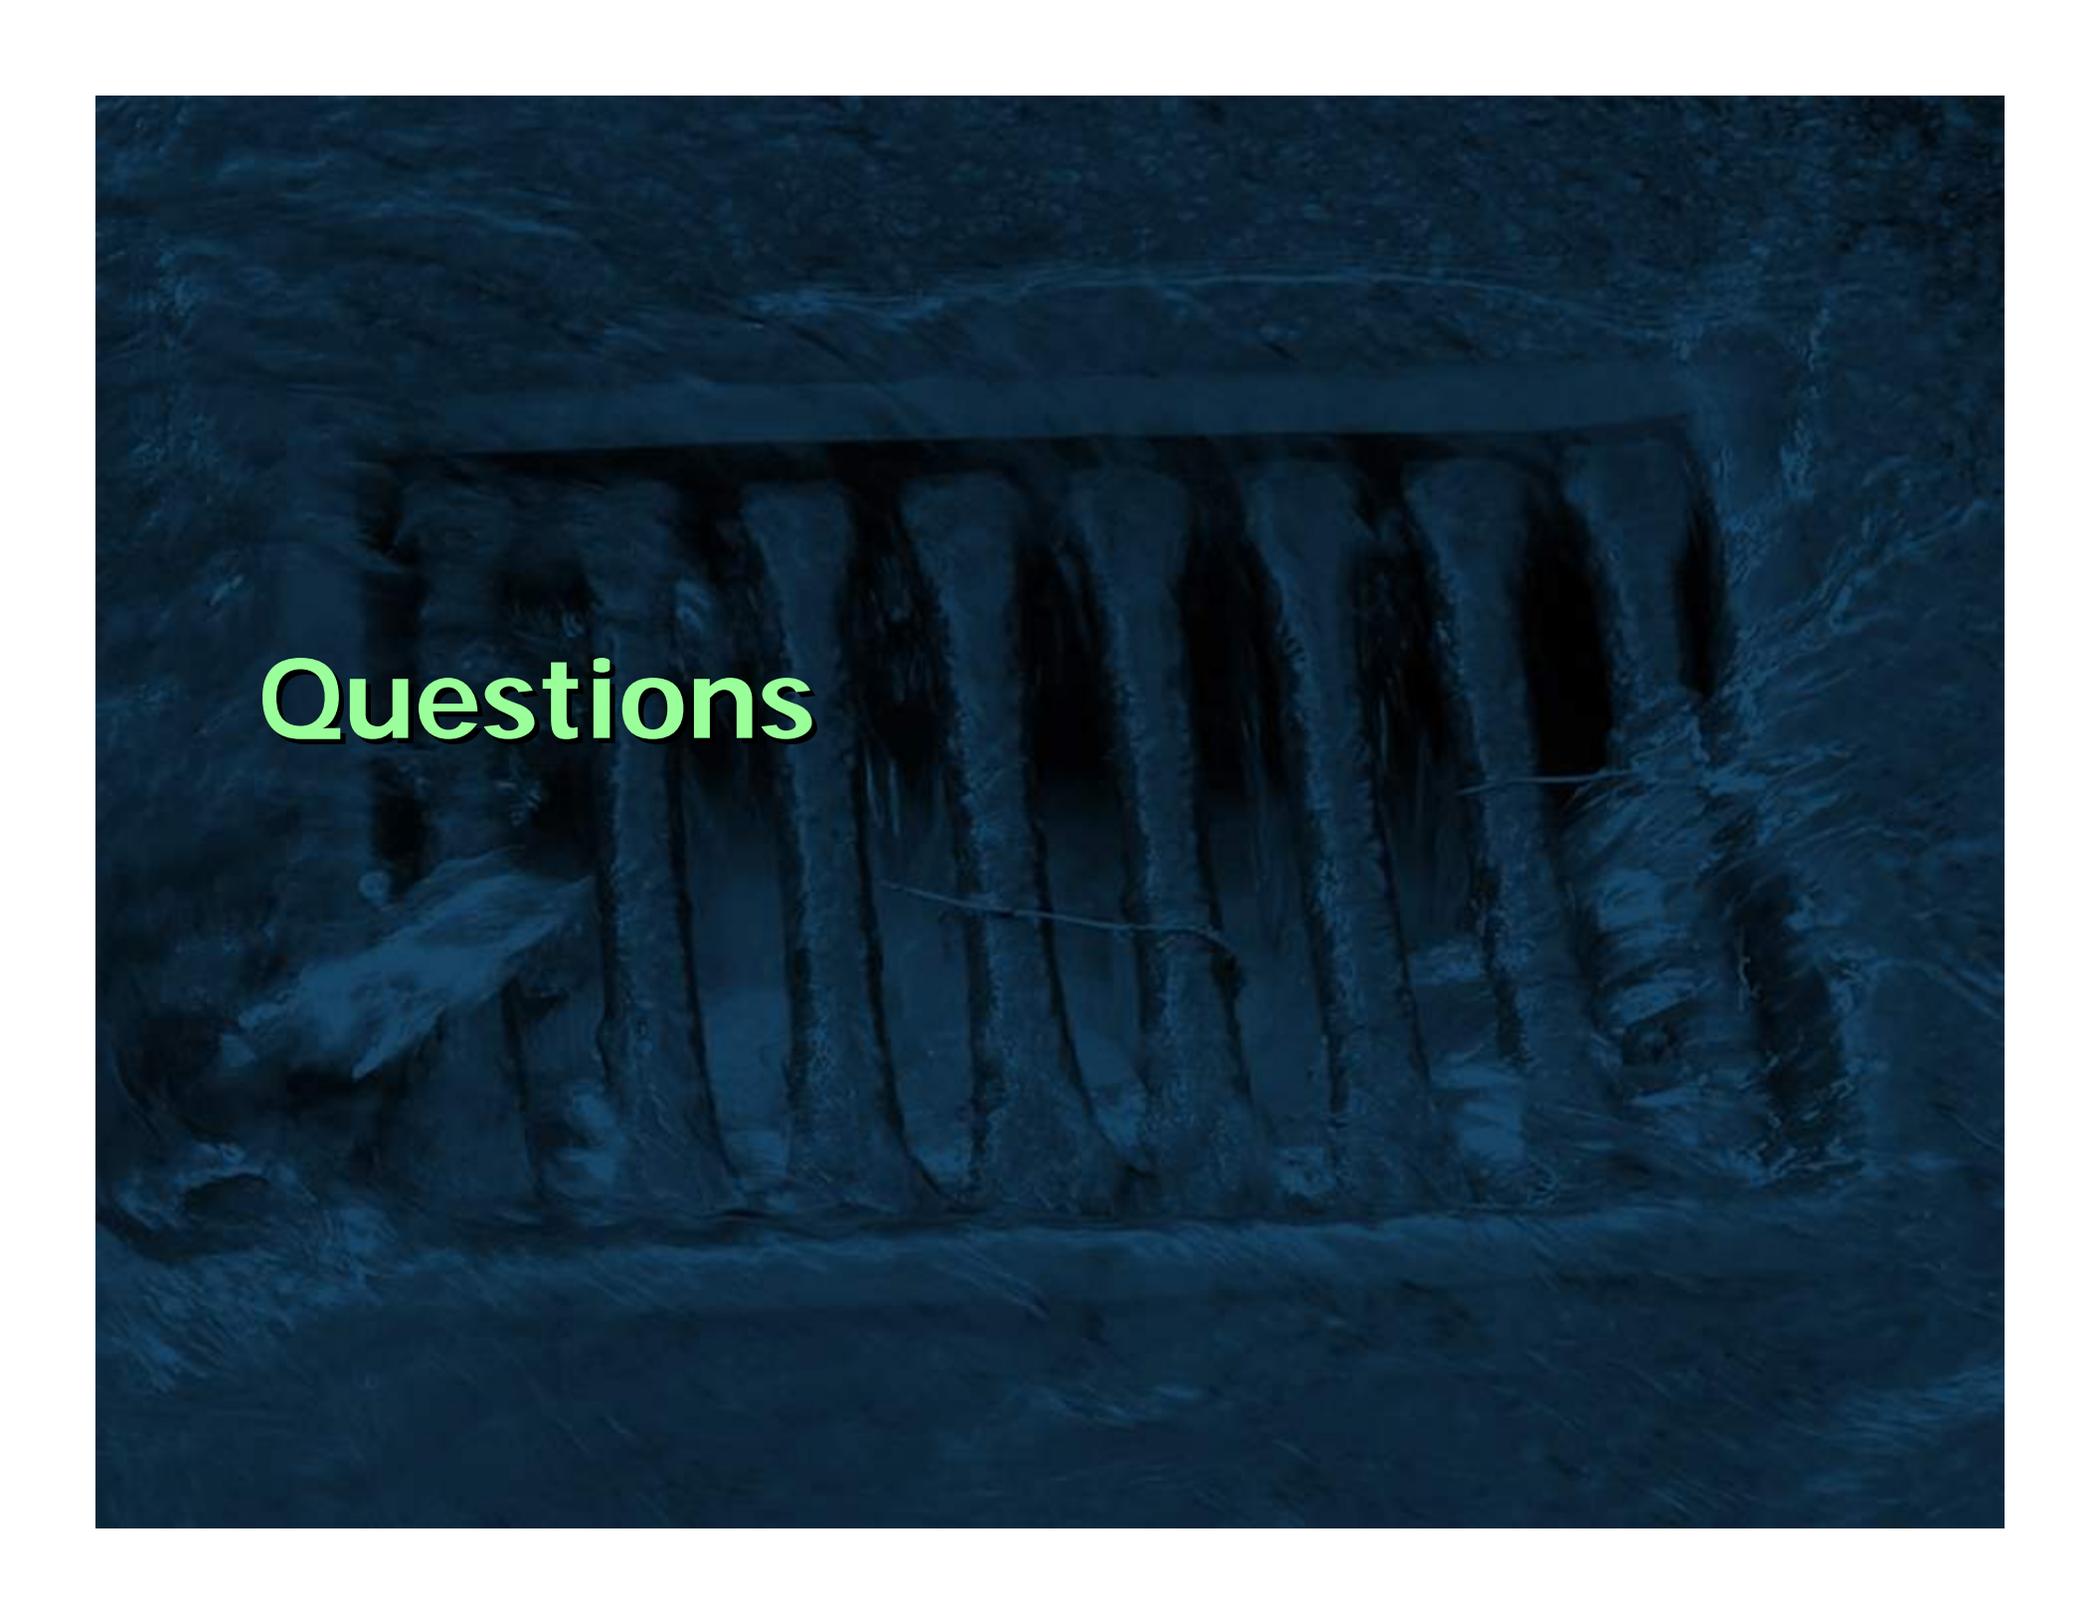

*that disturb one acre or more, including smaller projects that are part of a larger, common plan of development.

Post-Construction: Key Elements

- **Ordinance covering new development and redevelopment**
 - Requirements for plan review
 - Reference design criteria
 - Maintenance requirements
 - Fines and penalties
- **Developed or adapted design criteria, which include low impact BMPs**
- **Plan review process with trained staff**
- **Maintenance program**
- **Trained inspection staff**

Municipal Operations

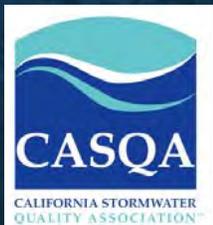

- **Develop a program to prevent stormwater pollution from municipal operations**
 - Training for employees
 - Standard operating procedures
 - Covers parks, building and fleet maintenance, construction, roads, streets, parking lots, maintenance yards, waste transfer stations, etc.

Questions

Approach to Municipal Program Effectiveness Assessment

California Stormwater Quality Association (CASQA)

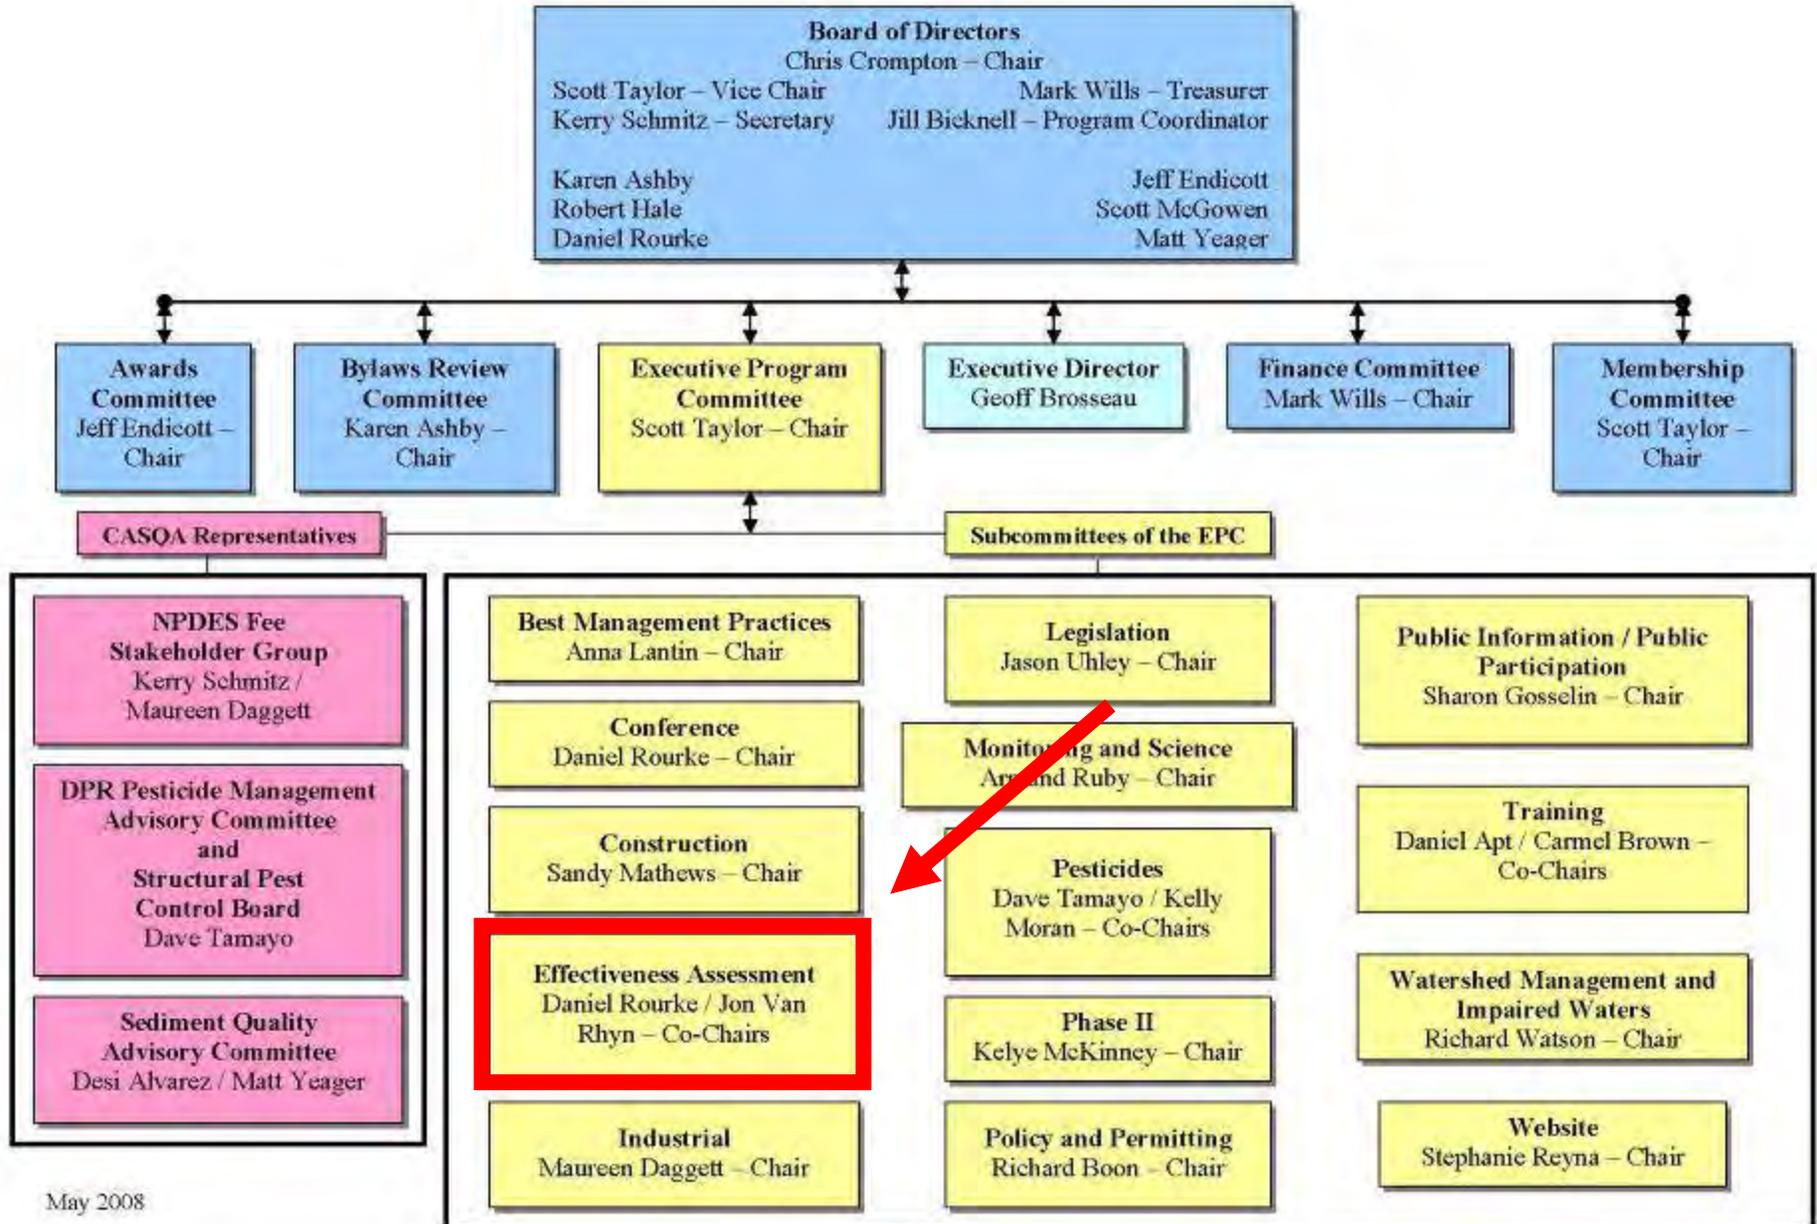

Introduction to CASQA

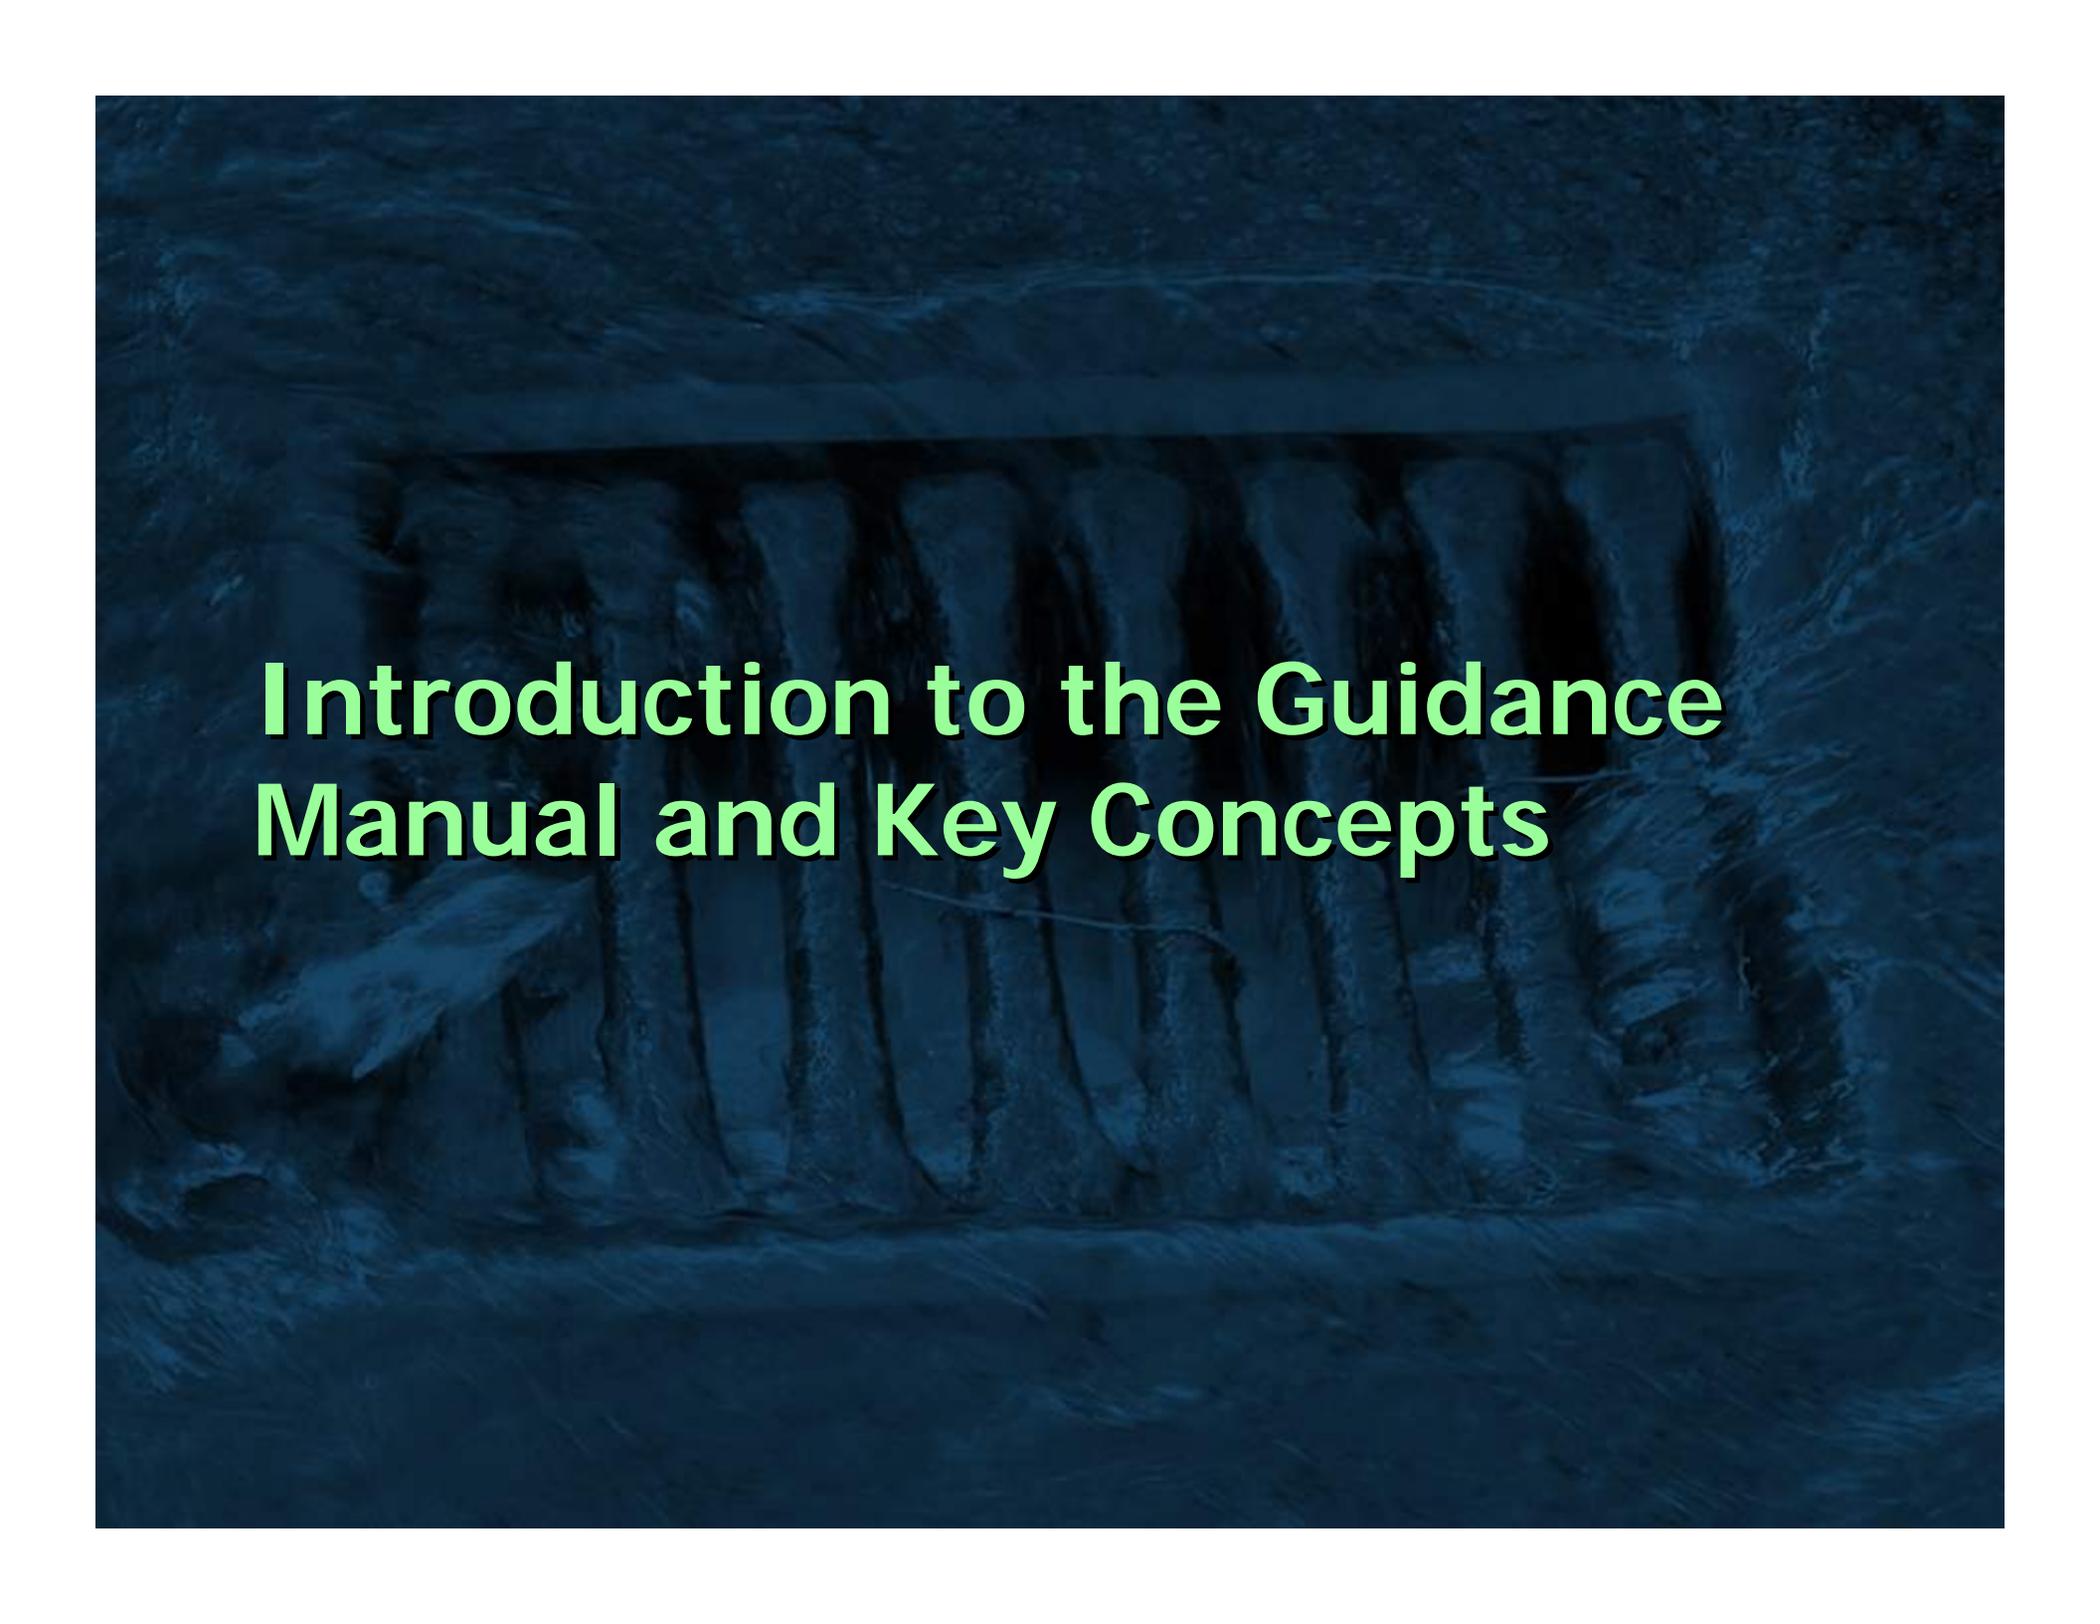

- Formed in 1989 as the SWQTF
- Transitioned to CASQA in 2002
- CASQA is a 501(c)(3) non-profit
- Membership comprised of a diverse range of stormwater professionals
- Hold bi-monthly meetings and an annual conference
- Board of Directors and Executive Program Committee

www.casqa.org

California Stormwater Quality Association (CASQA) 2008 Organizational Structure

Introduction to the Guidance Manual and Key Concepts

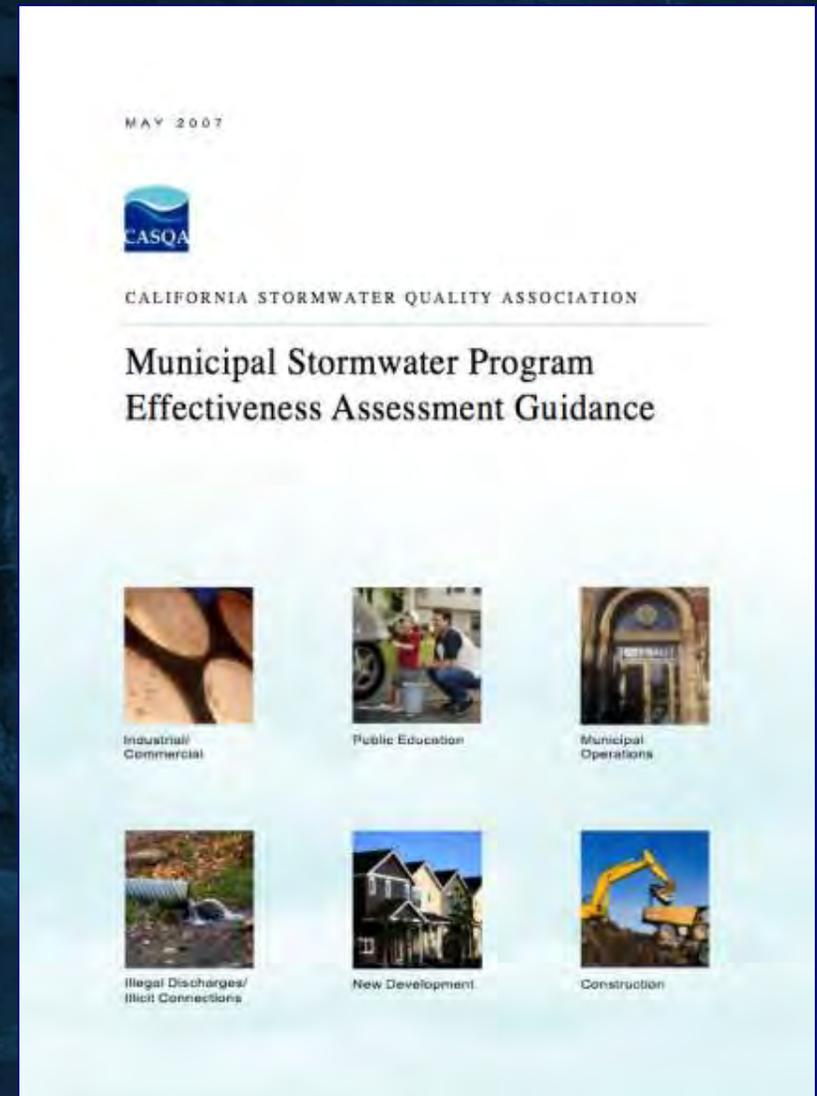

History of Guidance Document

- Regulatory requirements in permits
- Municipalities unsure how to conduct these assessments
- CASQA identified a need for a guidance document – worked with committee
- Developed white paper and then guidance document
- Received regulatory support

White Paper ~ 2 Years → Guidance Document

Guidance Document Approach

- Defines terms and key concepts
- Presents an assessment strategy
- Describes different assessment methods
- Identifies applicability to program elements/minimum control measures
- Provides examples

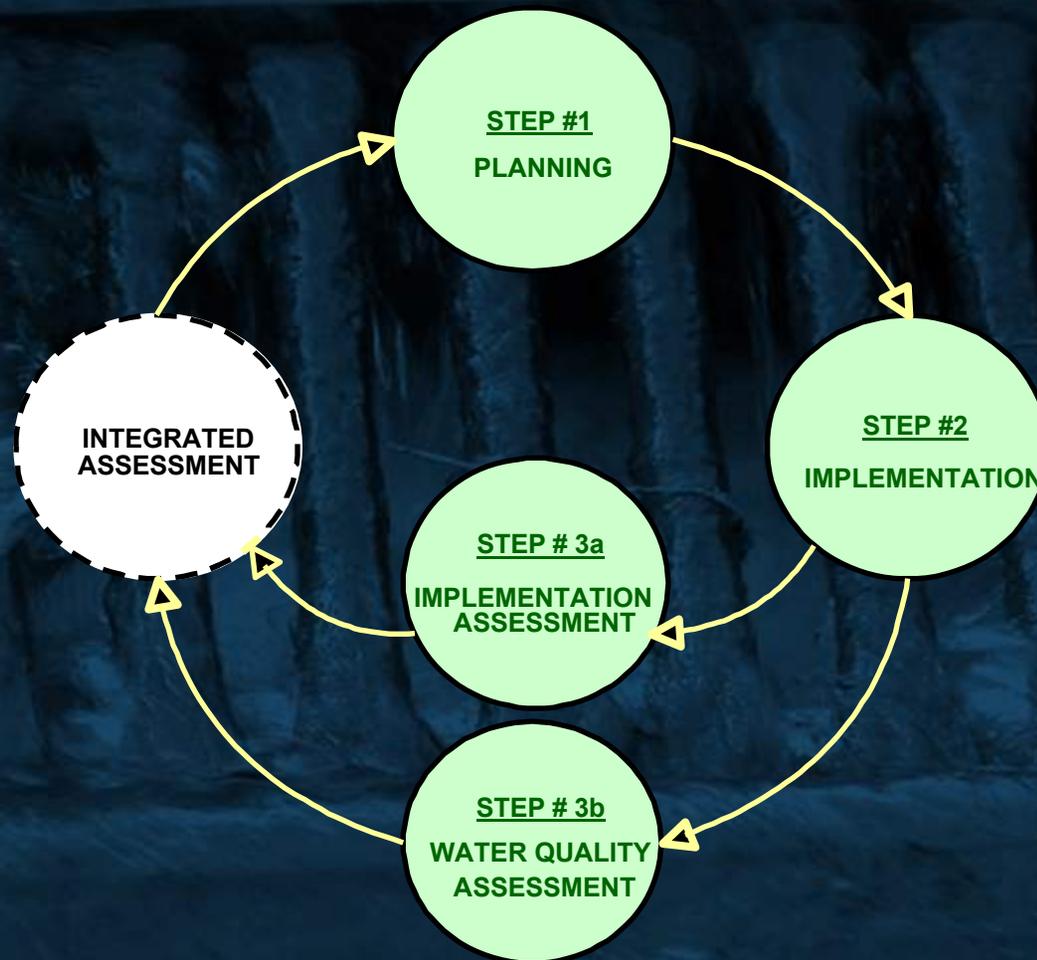

Why Conduct Effectiveness Assessments?

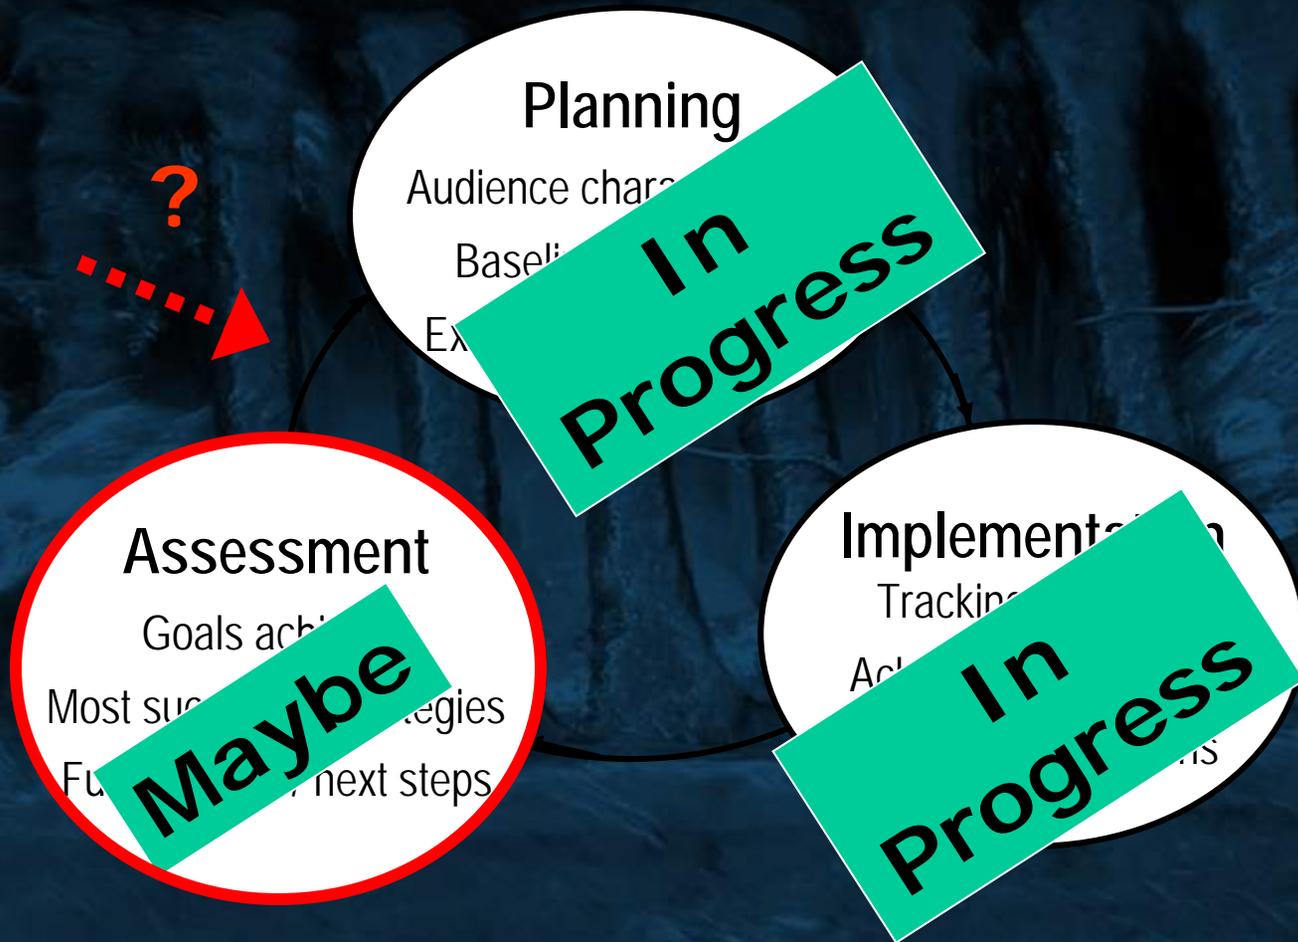

Use the Results to:

- Determine if the program is progressing towards its intermediary and long term goals
- Determine if data is meaningful
- Focus/ modify the program
- Identify resource needs
- Meet permit requirements

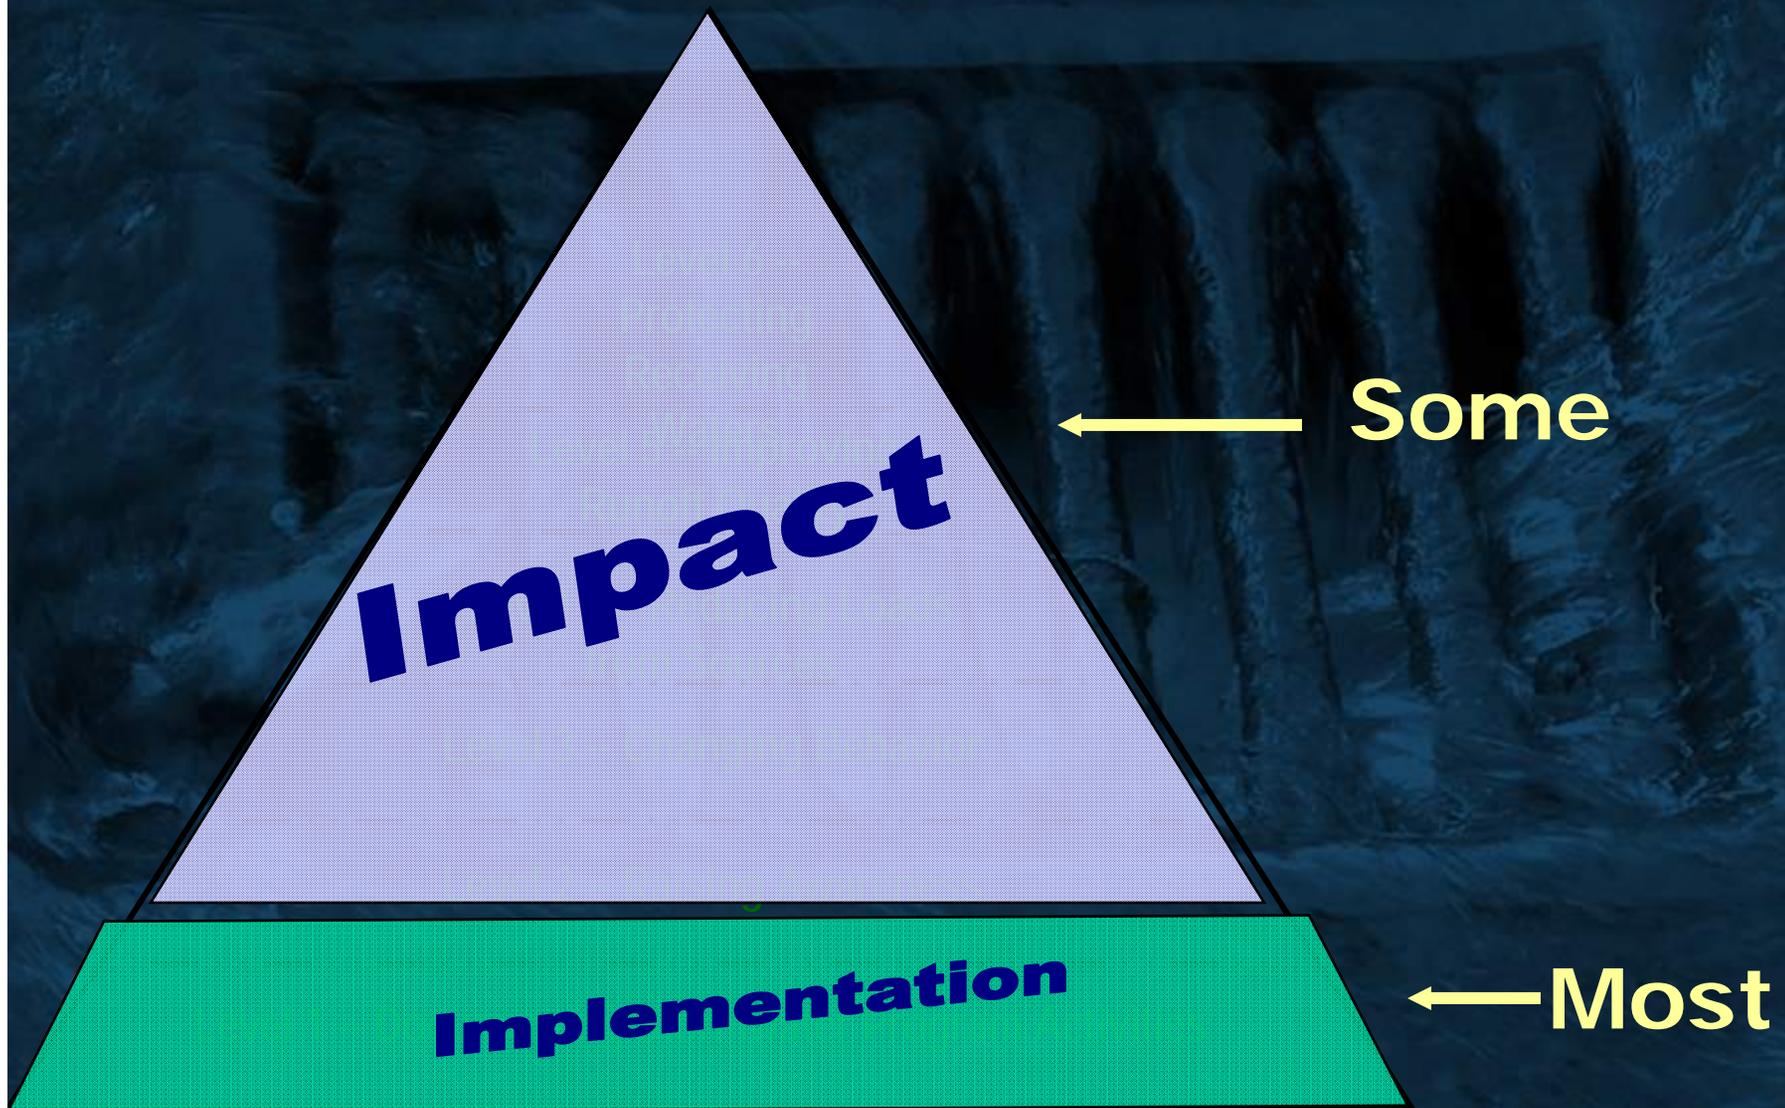

How Can We Adaptively Manage the Programs with Assessment?

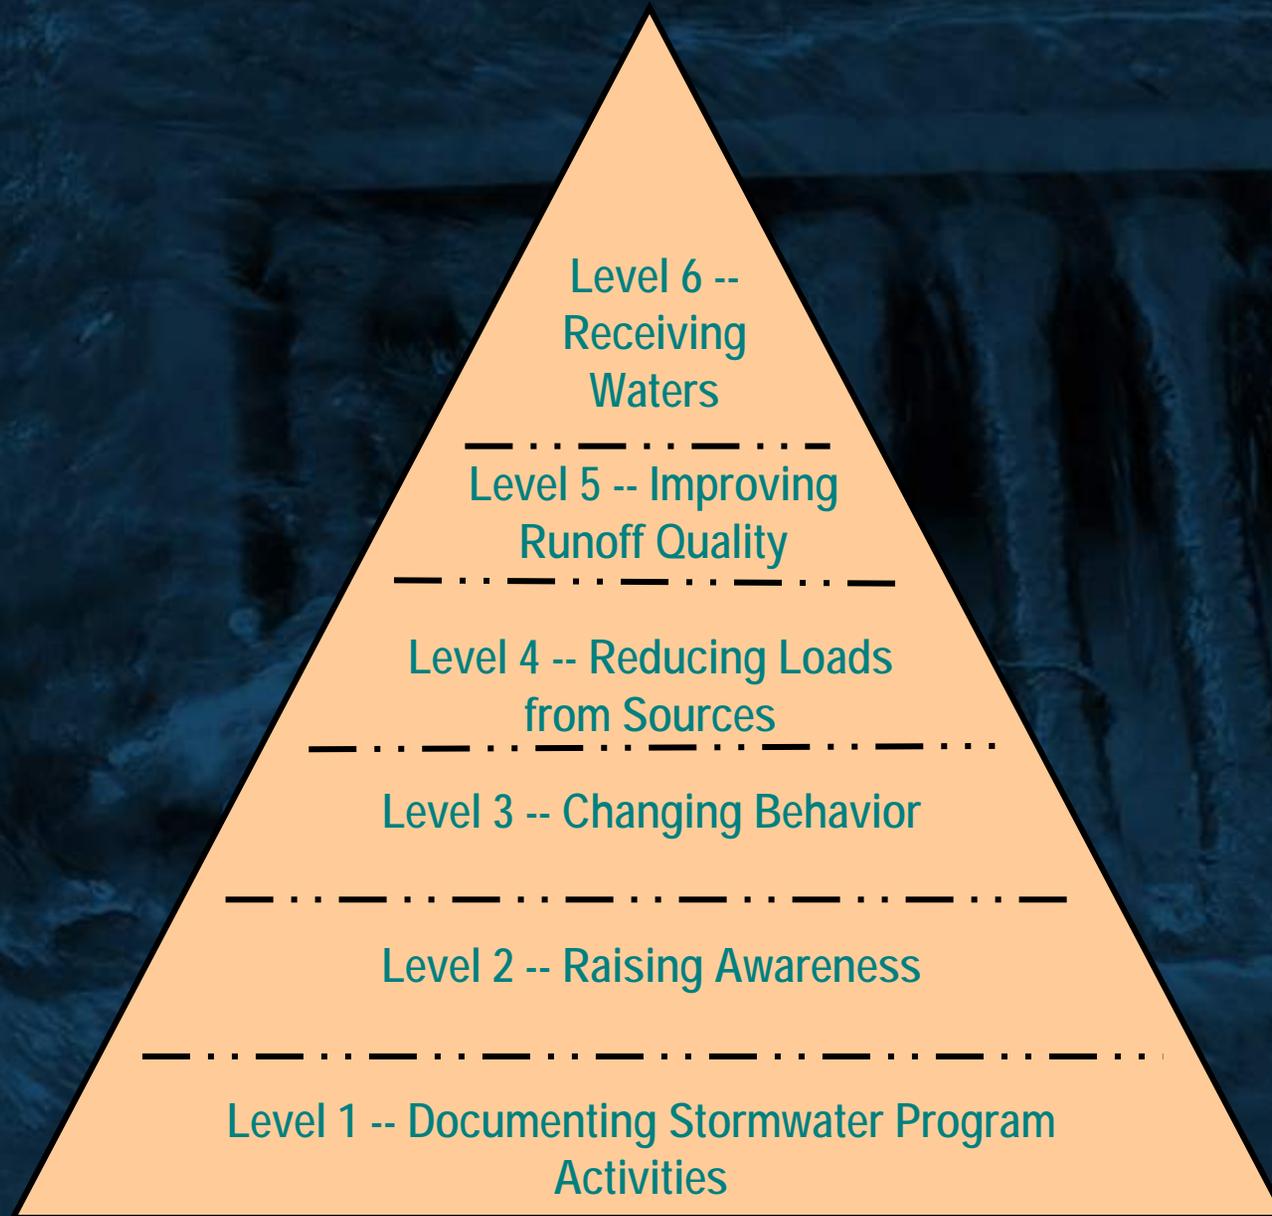

Where are We Now in Adaptively Managing the Programs?

How Do We Currently Assess Effectiveness?

How Can We Assess Effectiveness?

Program
(Levels 5-6)

Element
(Levels 2-5)

Activity
(Levels 1-4)

Not All Outcome Levels Apply

Minimum Control Measure	Outcome Levels					
	Level 1	Level 2	Level 3	Level 4	Level 5	Level 6
Public Education & Outreach	X	X	X			
Public Participation/ Involvement	X	X	X			
Illicit Discharge Detection and Elimination	X	X	X			
Construction Site Runoff	X	?	X	X		
Post-Construction Runoff Control	X	?	X	X		
Pollution Prevention/ Housekeeping	X	X	X	X		

Effectiveness Assessment Strategy

- Determining Assessment Focus
- Determining Baseline Condition
- Selecting Assessment Method(s)
- Using the information

Assessment Focus

- Is the activity being implemented (Level 1)?
- Does the activity/element raise awareness (Level 2)?
- Does the activity/element change behavior (Level 3)?
- Does the activity/element reduce loads from sources (Level 4)?
- Does the element/program result in improved runoff quality (Level 5)?
- Has a measurable change been observed in receiving waters (Level 6)?

Establishing Assessment Focus

- What are you trying to achieve?

Goal

- Where are you starting from?

Baseline

- How will you know if the goal has been achieved?

Target

- What is the desired outcome?

Outcome Level

Example Goals, Targets, and Outcome Levels

Goal	Target	Outcome Level
Increase the implementation of proper protocols for storm drain cleaning.	All storm drains are inspected and cleaned	1
Decrease chemical use for landscape maintenance.	Decrease pesticide use by 20% in targeted locations	3

Effectiveness Assessment Strategy

- Determining Assessment Focus
- Determining Baseline Condition
- Selecting Assessment Method(s)
- Using the information

Example Baseline Information

- What have we done - what do we know? (Level 1)
- Is the target audience aware – did they change behavior? (Level 2)
- Can we use a past survey? (Levels 2, 3)
- Do we have baseline monitoring data? (Levels 4, 5, 6)

Effectiveness Assessment Strategy

- Determining Assessment Focus
- Determining Baseline Condition
- Selecting Assessment Method(s)
- Using the information

Selecting Assessment Methods

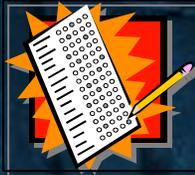

- Confirmation

- Tabulation

- Surveys

- Inspections/
Observation

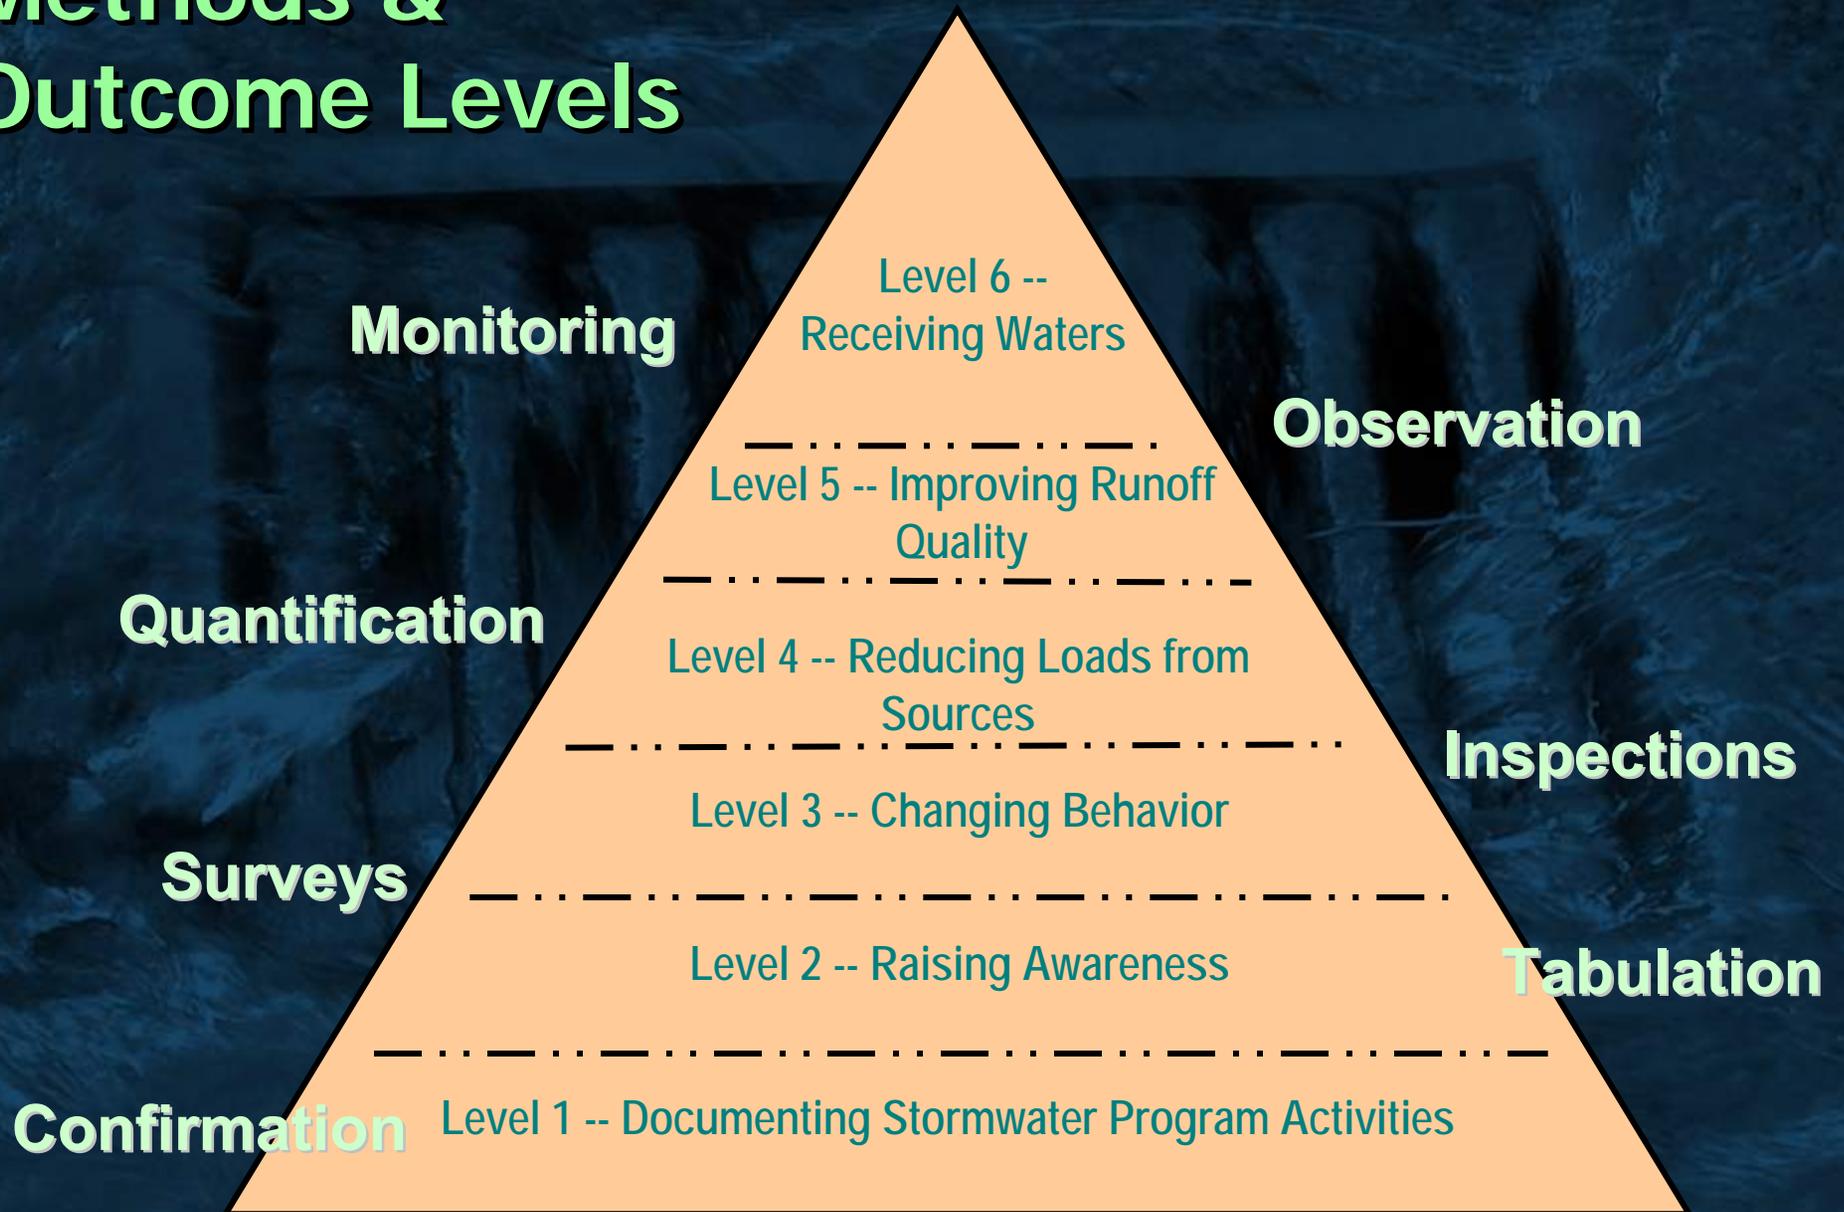

- Quantification

- Monitoring

Methods & Outcome Levels

Example - Setting a target/ Selecting a method

- Goal: Reduce pesticide use.

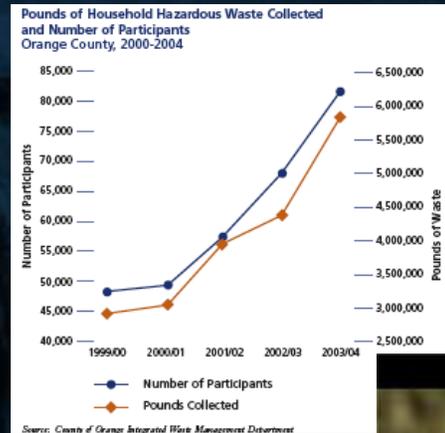

Target	Data Collected	Assessment Method
Use protocols to reduce pesticide use by municipal staff by 50%	Pounds of pesticide active ingredient used	Tabulation Quantification
Conduct outreach to reduce pesticide use by residents by 10%	Reported Use Shelf survey, sales tracking	Surveys Tabulation

Effectiveness Assessment Strategy

- Determining Assessment Focus
- Determining Baseline Condition
- Selecting Assessment Method(s)
- Using the information

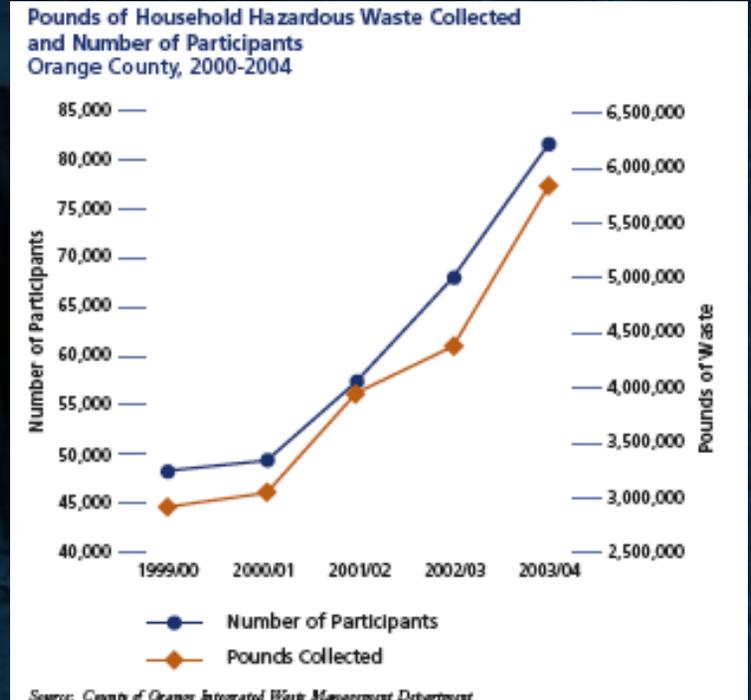

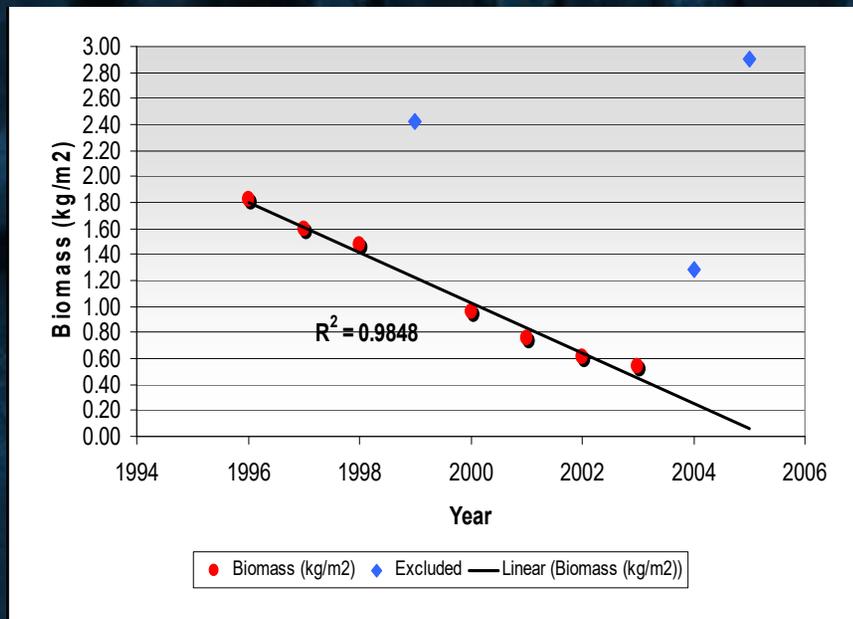

Using the information

- Data analysis
- Future planning
- Reporting & communicating

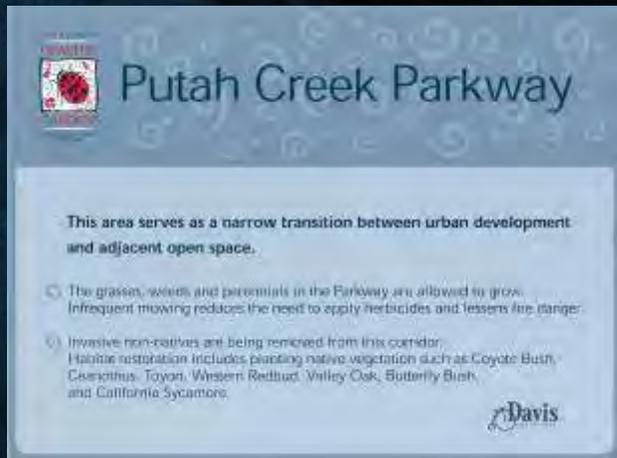

Using the information

- Data analysis
 - Observed changes
 - Trends
 - Quantitative analysis

Interpreting Data for Future Planning

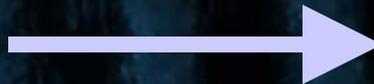

Putah Creek Parkway

This area serves as a narrow transition between urban development and adjacent open space.

- The grasses, weeds and perennials in the Parkway are allowed to grow. Infrequent mowing reduces the need to apply herbicides and lessens fire danger.
- Invasive non-natives are being removed from this corridor. Habitat restoration includes planting native vegetation such as Coyote Bush, Ceanothus, Toyon, Western Redbud, Valley Oak, Butterfly Bush, and California Sycamore.

• Theatre slides more effective than signs

• Relate message to wetlands

• Move from awareness to behavior change

My beak is natural. Pesticides are not.

Know your pests before applying pesticides.
Help keep our ponds and wetlands healthy.

Overall Program and Water Quality Assessment

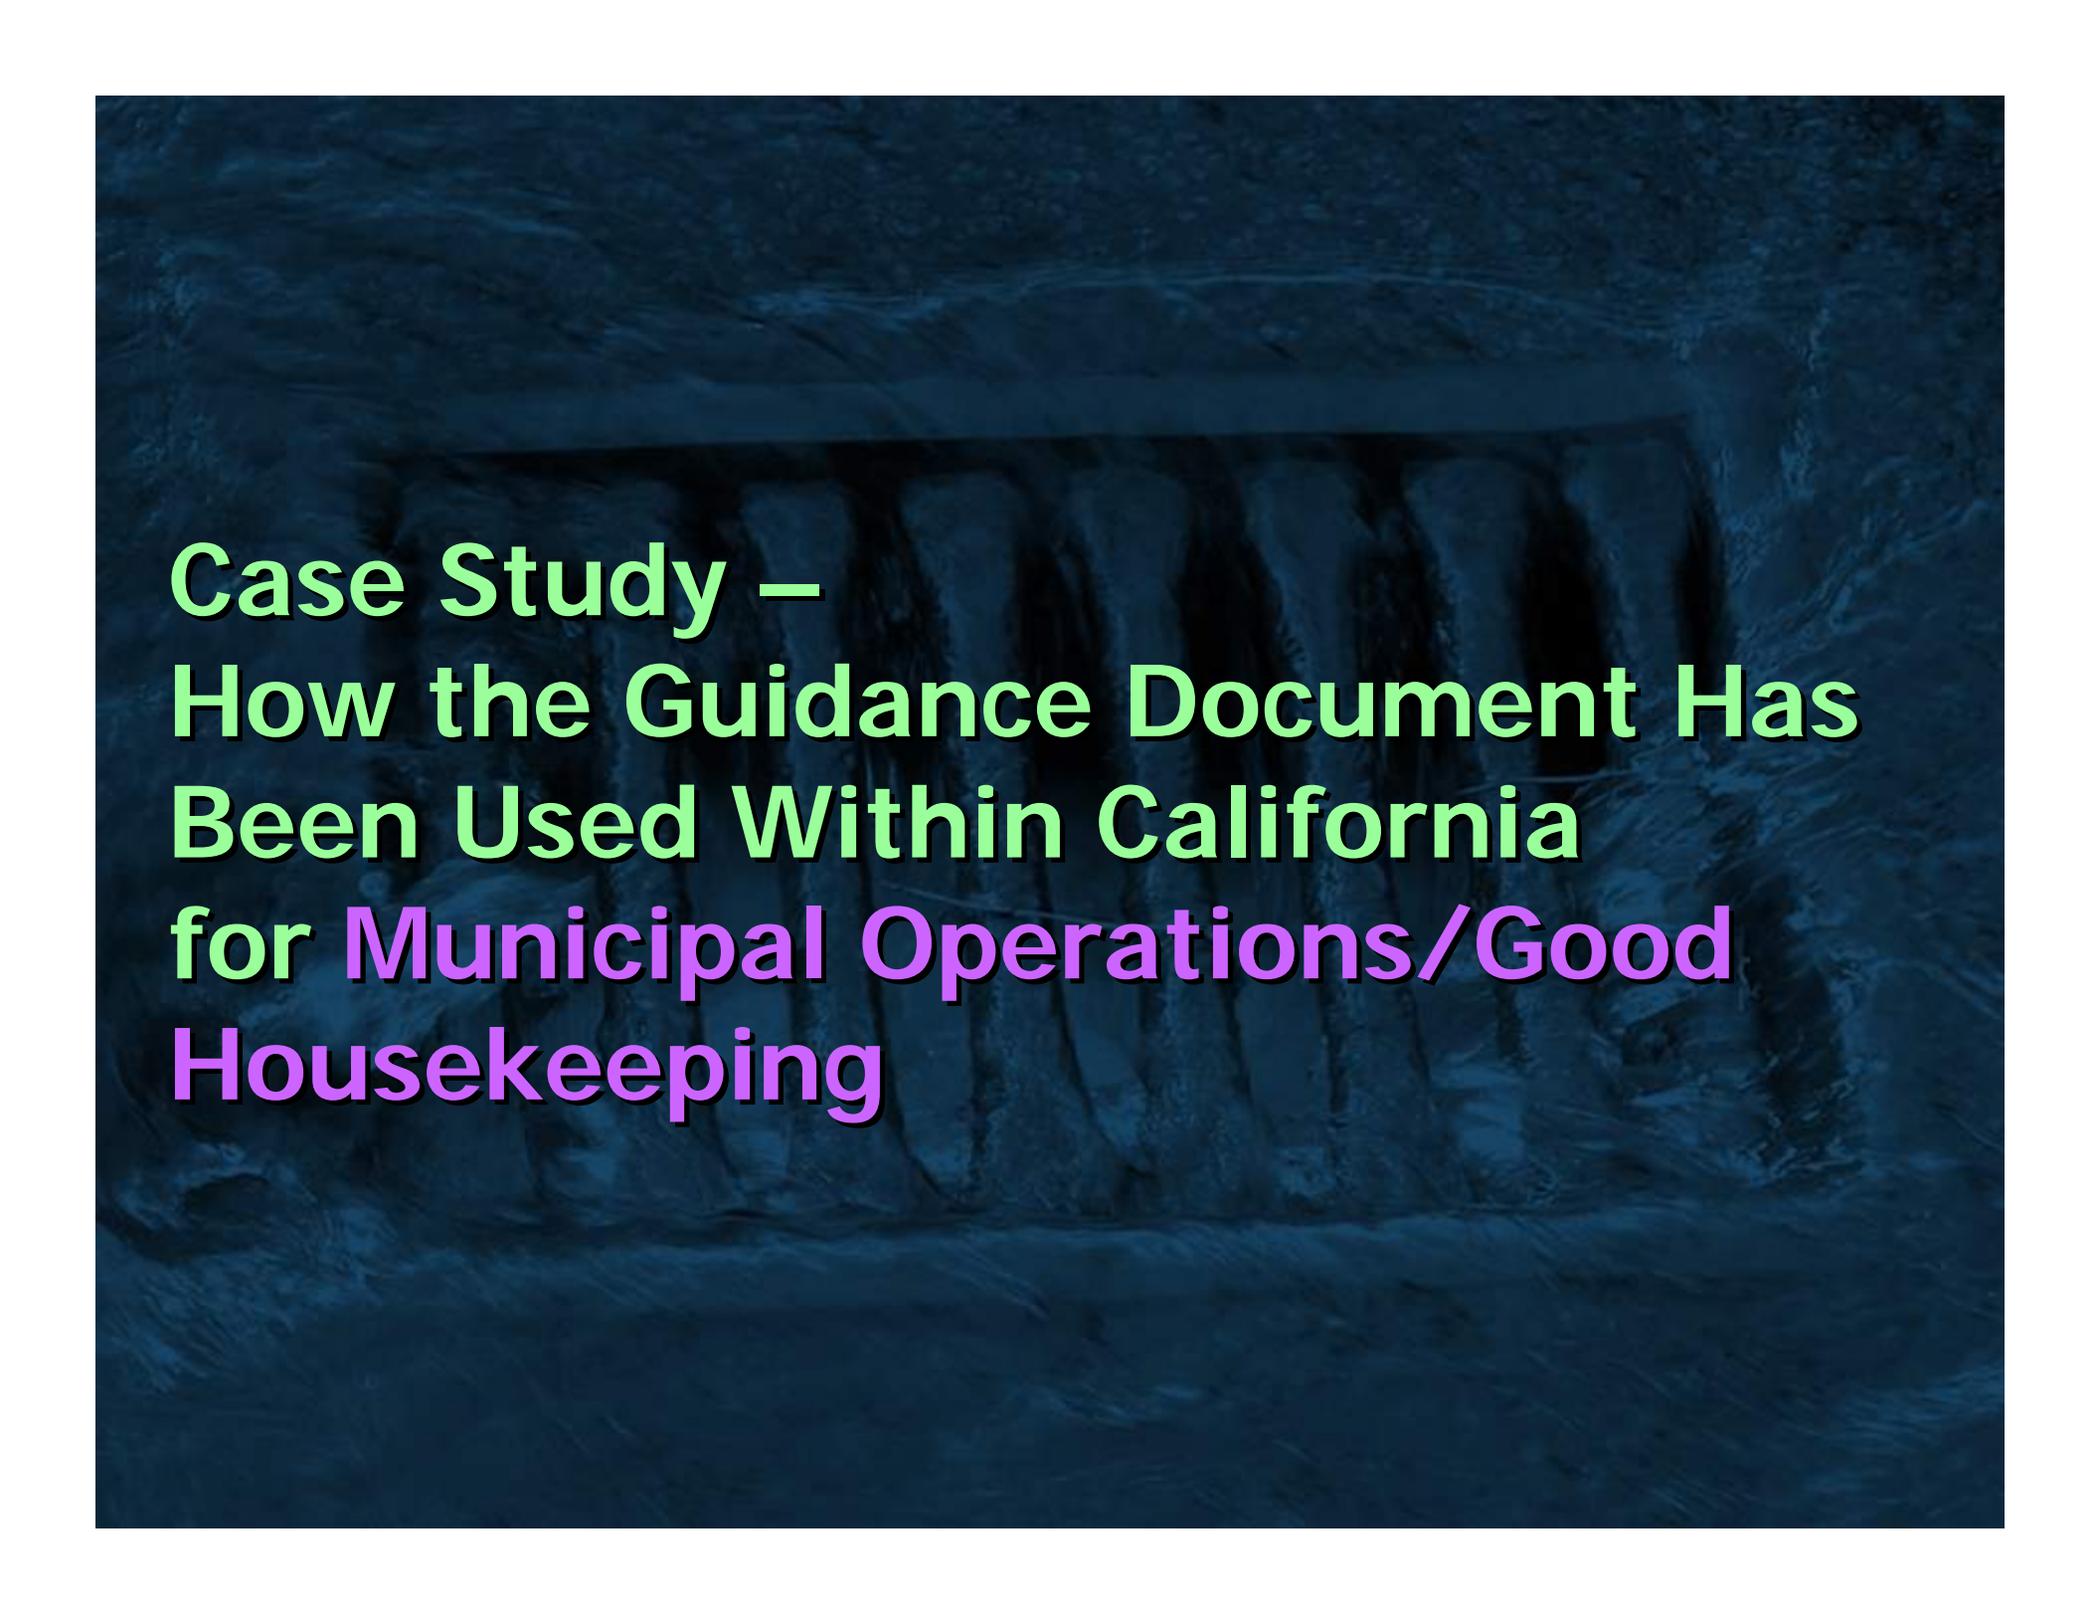

Increasing
Difficulty

Questions

**Case Study –
How the Guidance Document Has
Been Used Within California
for Municipal Operations/Good
Housekeeping**

Document Identifies How the Concepts Apply to Each Program Element/MCM

Municipal Operations Program Element

Applicable Outcome Levels	
Level 1 – Documenting Activities	X
Level 2 – Raising Awareness	X
Level 3 – Changing Behavior	X
Level 4 – Reducing Loads from Sources	X
Level 5 – Improving Runoff Quality	*
Level 6 – Protecting Receiving Water Quality	*

*Levels 5 & 6 discussed in Section 6

Identifies Example Goals Outcomes

Outcome Level	Goal	Example Outcomes
1 – Documenting Activities	Program development and implementation and basic compliance with the NPDES permit requirements.	<ul style="list-style-type: none"> • Perform street sweeping at a defined frequency and coverage • # of storm drain inlets cleaned • # of responses to complaints/ flood notifications
2 – Raising Awareness	Raise a target audience's awareness and understanding of an issue	<ul style="list-style-type: none"> • Develop a Facility Pollution Prevention Plan (FPPP) for Corporation Yard • % field maintenance staff who understood training concepts
3 – Changing Behavior	Change a target audience's behavior which results in the implementation of recommended BMPs	<ul style="list-style-type: none"> • Implementation of FPPP at corporation yard. • Proper handling and disposal of street sweeping waste.
4 – Reducing Loads from Sources	Reduce the load of pollutants from sources <u>to</u> the storm drain system	<ul style="list-style-type: none"> • Estimates of pounds of pollutant removed by cleaning of storm drain inlets and sumps • Tons of dry waste removed from street sweeping

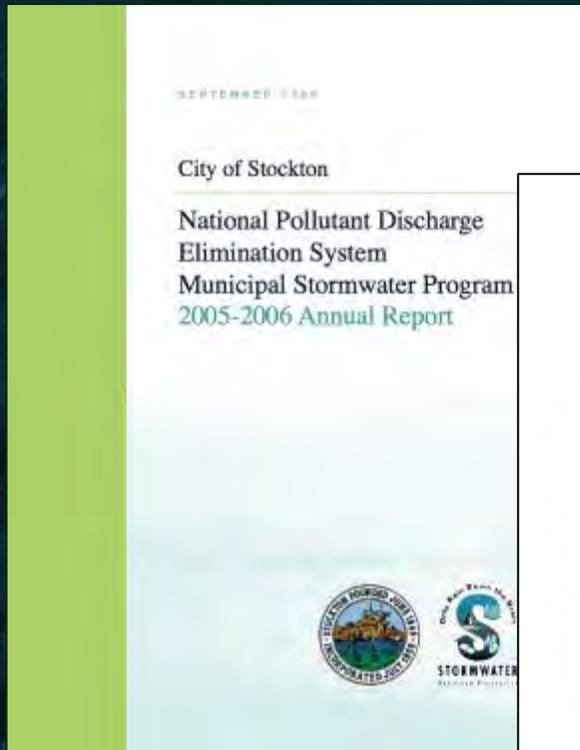

Identifies Example Goals and Targets

Goals	Target	Projected Timeframe
<p>Change a target audience's behavior which results in the implementation of recommended BMPs –</p> <p>Increase the implementation of proper protocols for storm drain cleaning.</p>	<p>All (or some feasible annual percentage) storm drains are inspected and cleaned consistent with prioritized schedule.</p>	<p>Within 2 years</p>
<p>Reduce the load of pollutants from sources <u>to</u> the storm drain system –</p> <p>Decrease chemical use for landscape maintenance.</p>	<p>Decrease pesticide use by 20% (taking in to account weather patterns and other factors) in targeted locations.</p>	<p>Within 3 years</p>

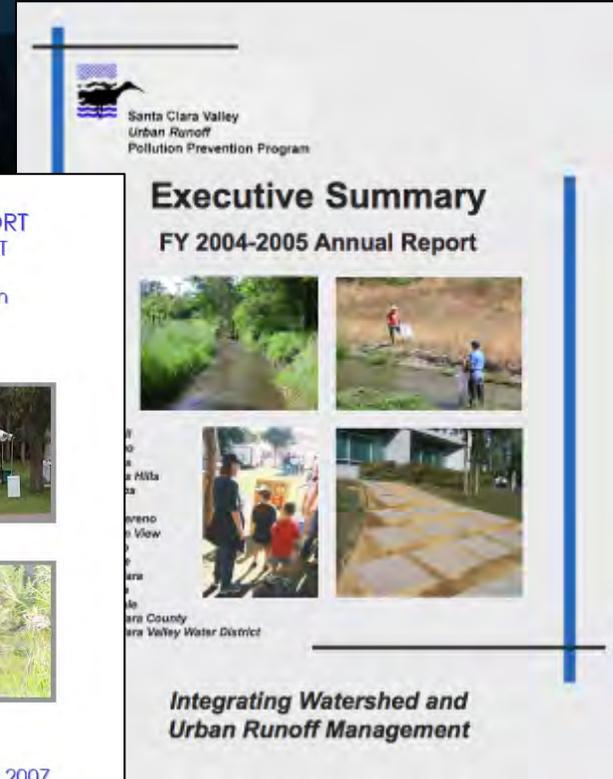

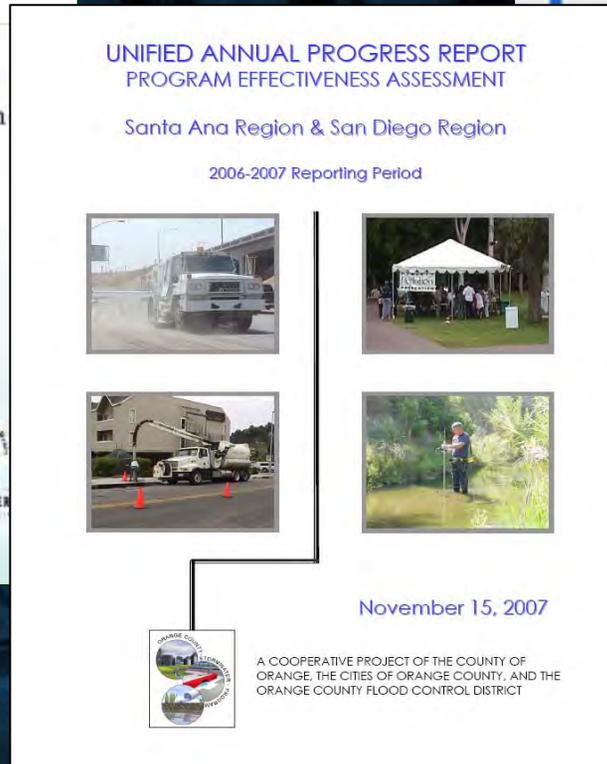

Examples for Reporting

Task	Data Collected	Outcome Level	Assessment Method and Comparison with Goals and Baselines
Storm Drain System Maintenance			
Inventory drainage system (by drainage area or sub-watershed)	Develop inventory/map of drainage system. Identify the location and size of drainage system including catch basins, pump stations, detention basins, etc.	1	Confirmation <ul style="list-style-type: none"> Identify that the inventory was developed Tabulation <ul style="list-style-type: none"> Identify total # catch basins and number directly draining to receiving water Provide map of drainage system
	Compile cleaning records for drainage system	1	
Develop and implement cleaning schedule and protocols	Develop protocols for cleaning	1-2	Confirmation <ul style="list-style-type: none"> Identify that protocols were developed Tabulation/Quantification <ul style="list-style-type: none"> # cleaned and estimate of waste removed.
	Number of catch basins, drain pipe, pump stations, etc. cleaned	2 – 4	

Some MS4s Are Already Using the Guidance Document

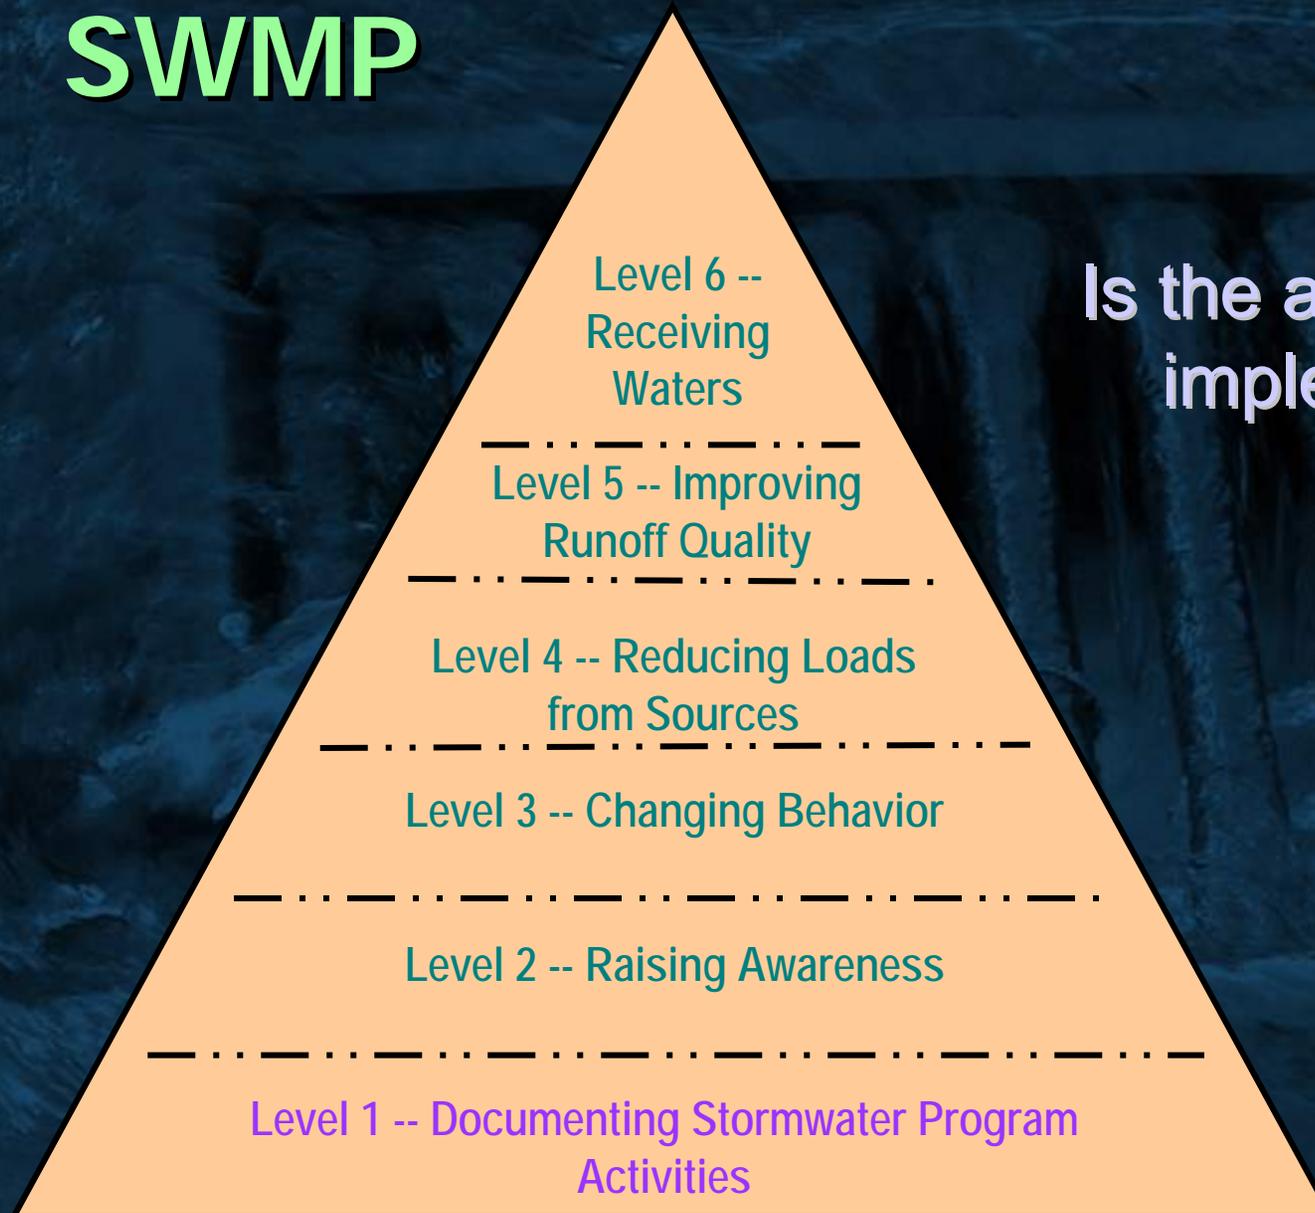

City and County of San Diego

Some Phase II MS4s

Outcome Levels and the SWMP

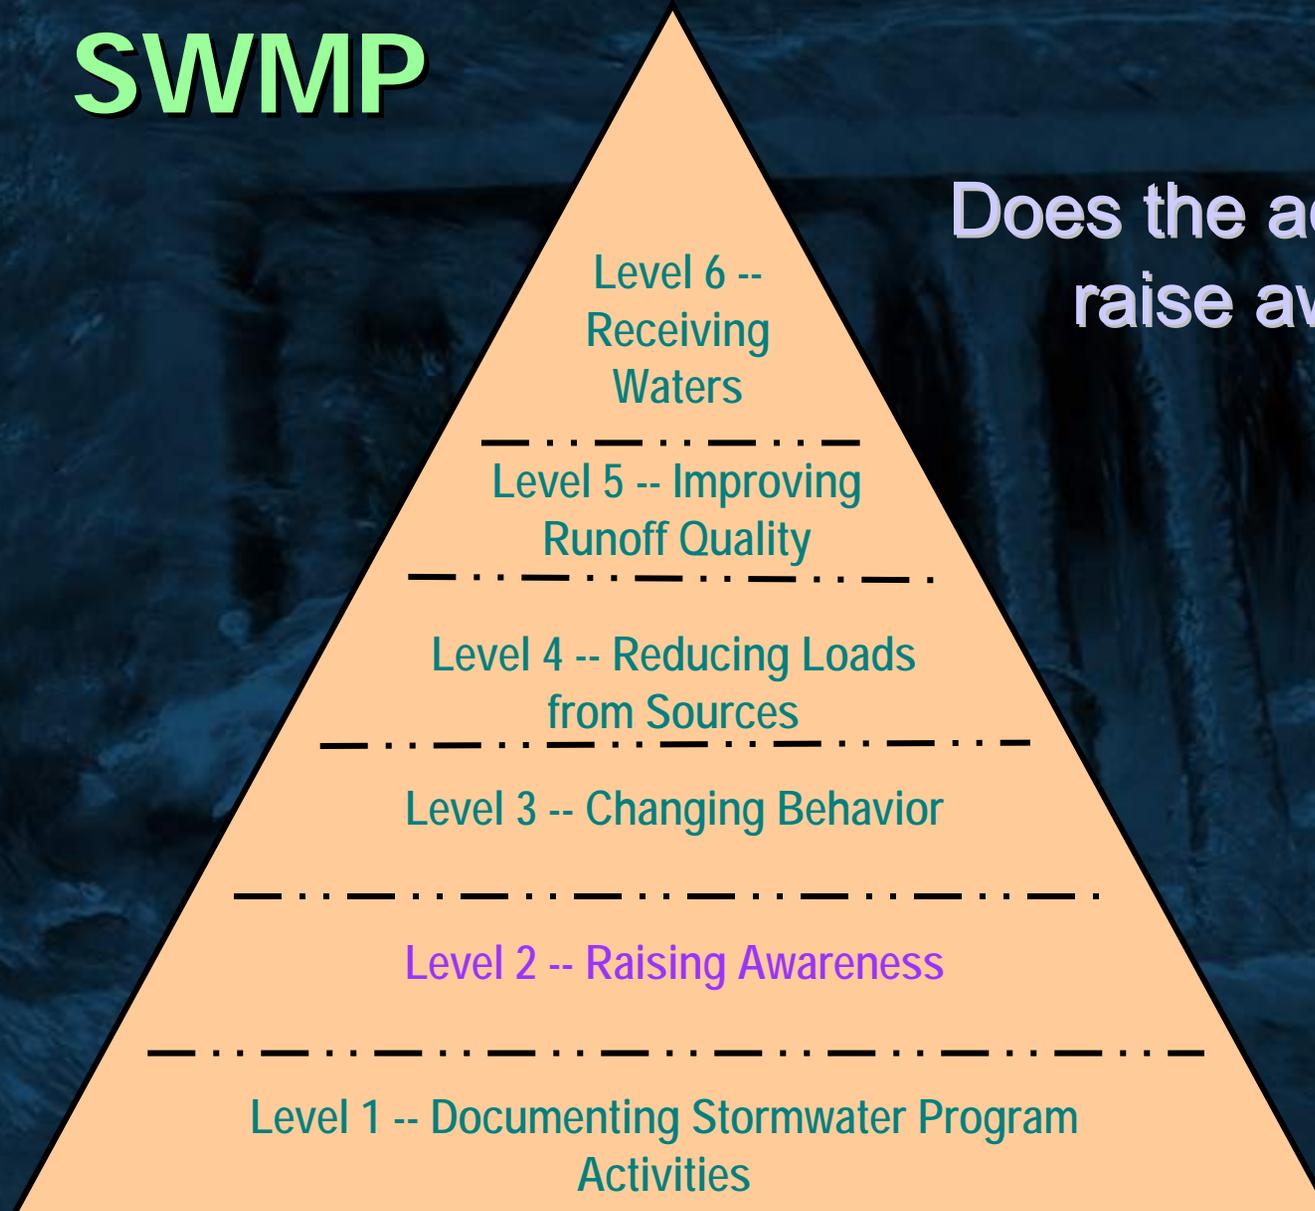

Is the activity being implemented?

Examples – Outcome Level 1

- Stenciled/marked catch basins
- Developed inspection forms
- Prioritized catch basins
- Annually inspected and cleaned catch basins

Source Type	Activity	Targeted Outcome	Measures of Success			
			Target	Actual	% Completion	Completion (Yes / No)
1. Roads, Streets, Highways, and Bridges	Inventory update	Task completion	---	---	---	Yes
2. MS4	Inventory conversion to GIS	Conversion of culverts (multi-year target)	100%	95%	---	---
3. Fixed Municipal Facilities	Inventory update	Task completion	---	---	---	Yes
4. Roads, Streets, and Highways	Sweeping	Streets swept (miles)	11,354	14,615	129%	---
5. MS4	Cleaning	Conveyances cleaned	15,540	16,402	106%	---
6. MS4	Stenciling	Inlets stenciled	137	137	100%	---
7. Municipal Employees	Basic Awareness Training	Employees trained	3,400	>18,000	100%	---
8. Municipal Employees	Focused Training	Employees trained	1,170	1,046	90%	---

Outcome Levels and the SWMP

Does the activity/element raise awareness?

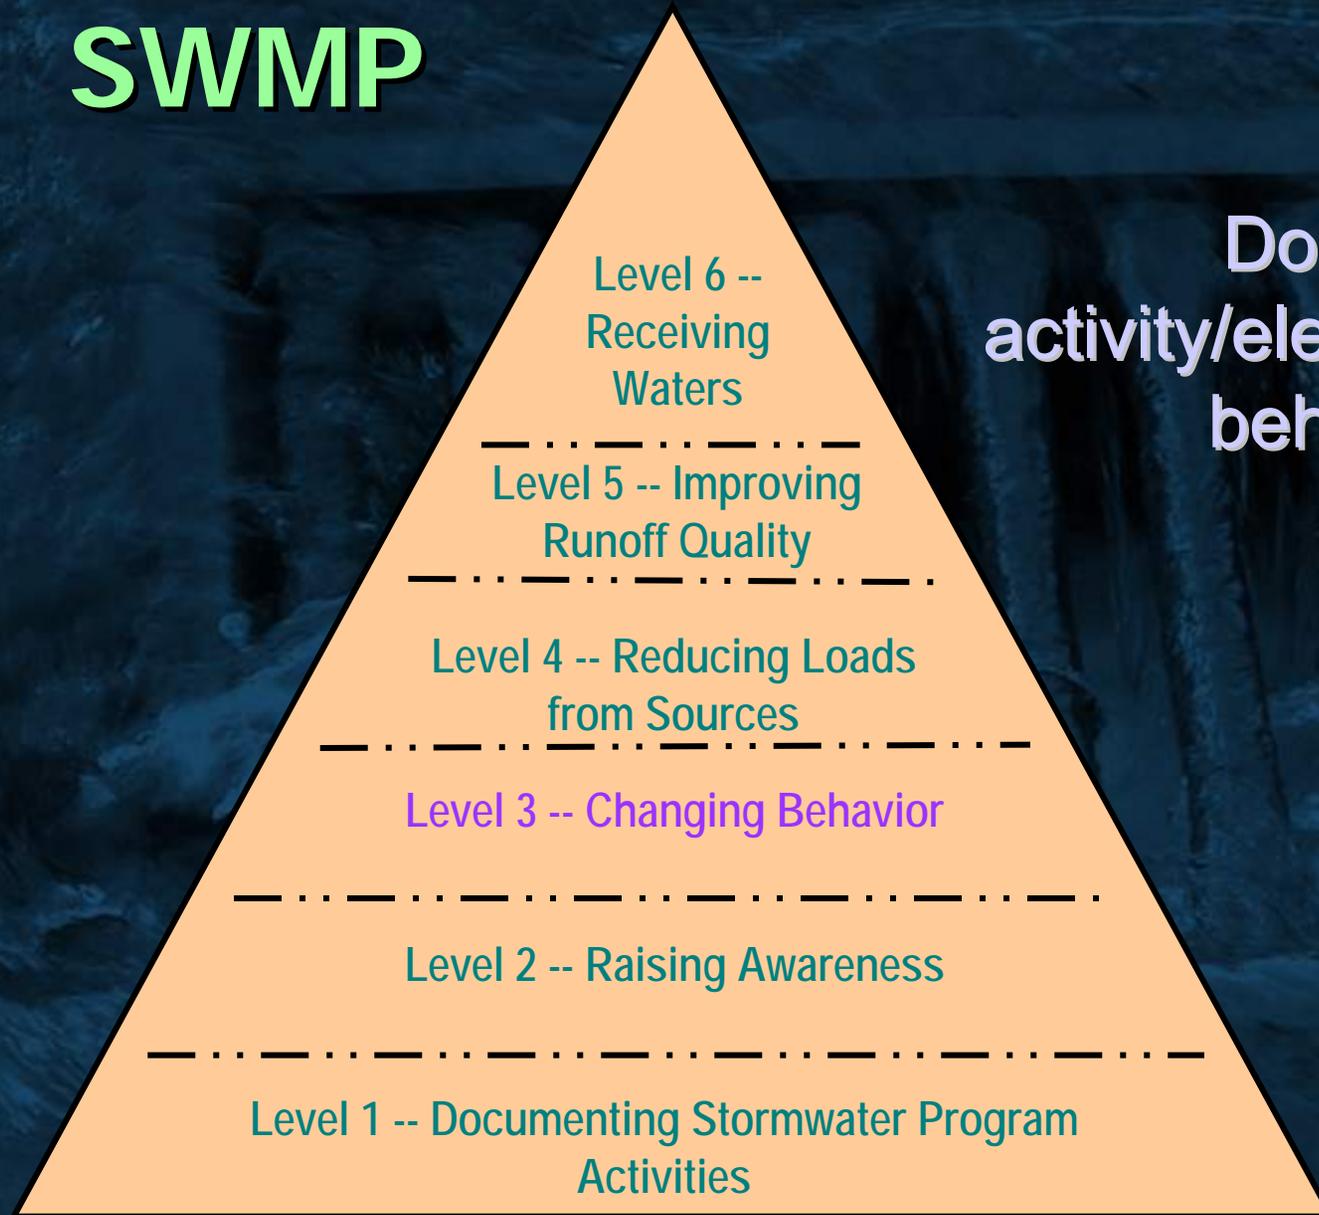

Example – Outcome Level 2

- Primarily achieved with training
- Recognize that Level 3 supports if Level 2 is achieved

Model IPM and Fertilizer Guidelines	Effectiveness Assessment Outcome Levels					
	Level 1	Level 2	Level 3	Level 4	Level 5	Level 6
	Implement Program	Increase Awareness	Behavior Change	Load Reduction	Runoff Quality	Receiving Water Quality
Model IPM	✓ Formal Policy		✓ Reduction in pesticide use			
Fertilizer Guidelines	Ⓜ Formal Policy		✓ Reduction in fertilizer use			
Training	✓ Track number/type of training sessions	Ⓜ Surveys show improved knowledge				

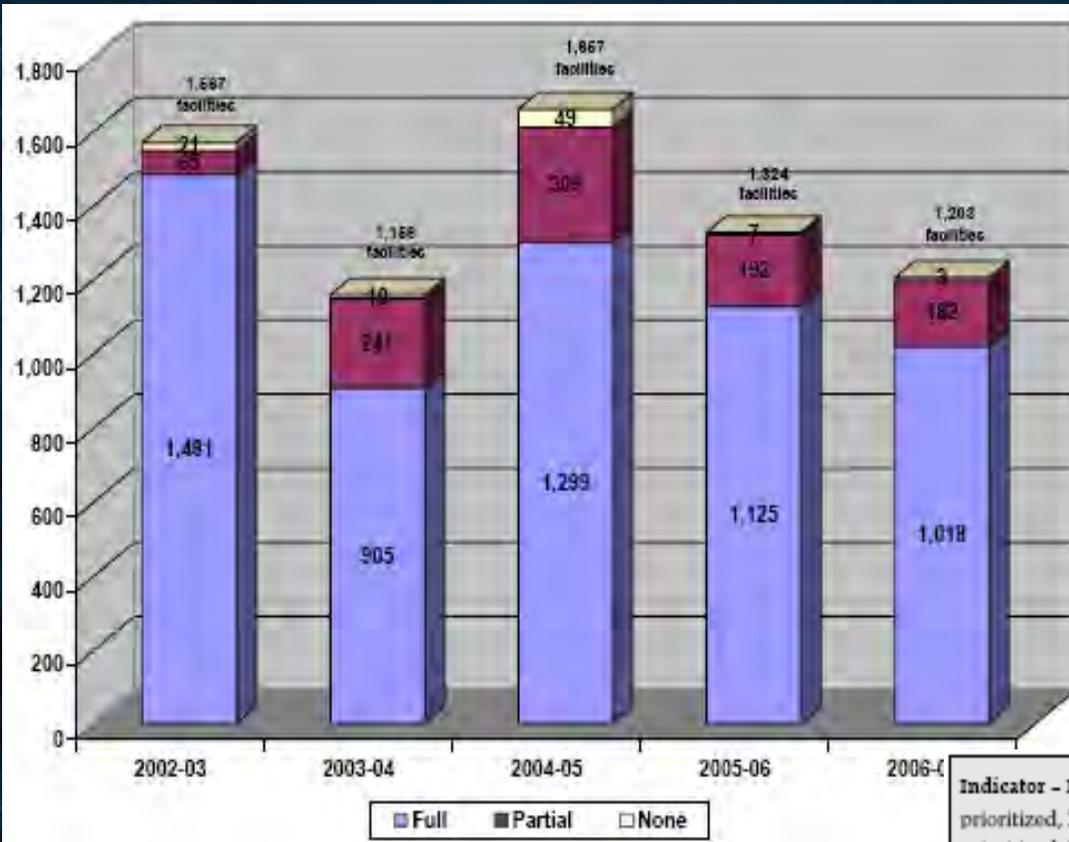

Key:
 ✓ = Currently Achieved Outcome Level
 Ⓜ = Potentially Achievable Outcome Level

Outcome Levels and the SWMP

Does the activity/element change behavior?

Example – Outcome Level 3

Evaluate BMP implementation at facilities

Indicator - Prioritization of Facilities: For 2006-07 1,203 municipal facilities were prioritized, 25% of which were high priority. In 2005-06 1,324 municipal facilities were prioritized, 27% of which were high priority; for 2004-05, 1,652 facilities were prioritized, 25% of which were ranked as high priority; for 2003-04, 1,156 facilities were prioritized, 29% of which were ranked as high priority; and for 2002-03, 1,587 facilities were prioritized, 26% of which were ranked as high priority (Table C-5.1 and Figure C-5.1).

- Level 1: Documenting Stormwater Program Activities
- Level 3: Changing Behavior

Outcome Levels and the SWMP

Does the activity/element reduce loads from sources?

Level 6 --
Receiving
Waters

Level 5 -- Improving
Runoff Quality

Level 4 -- Reducing Loads
from Sources

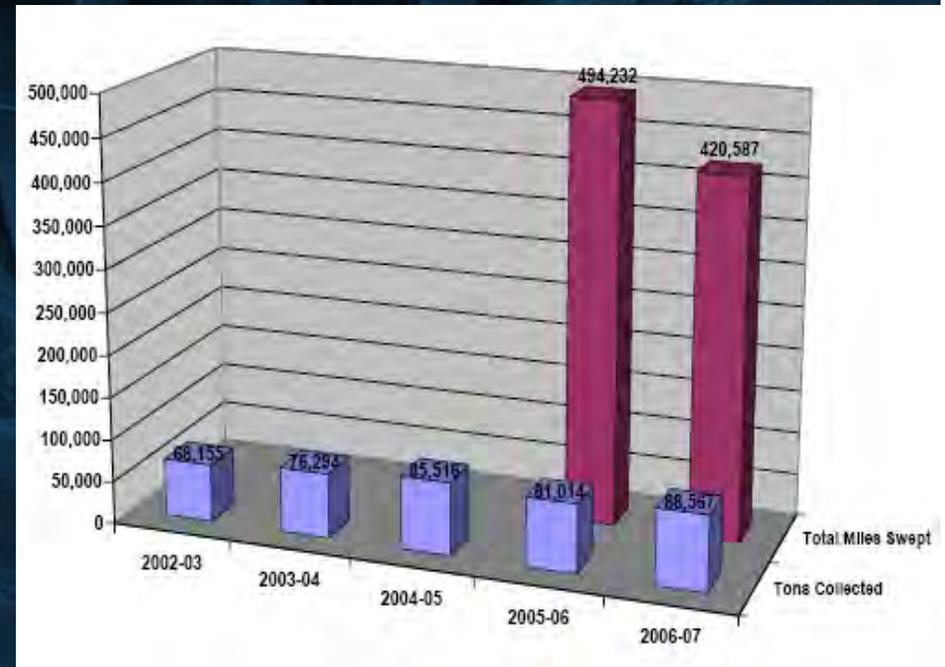

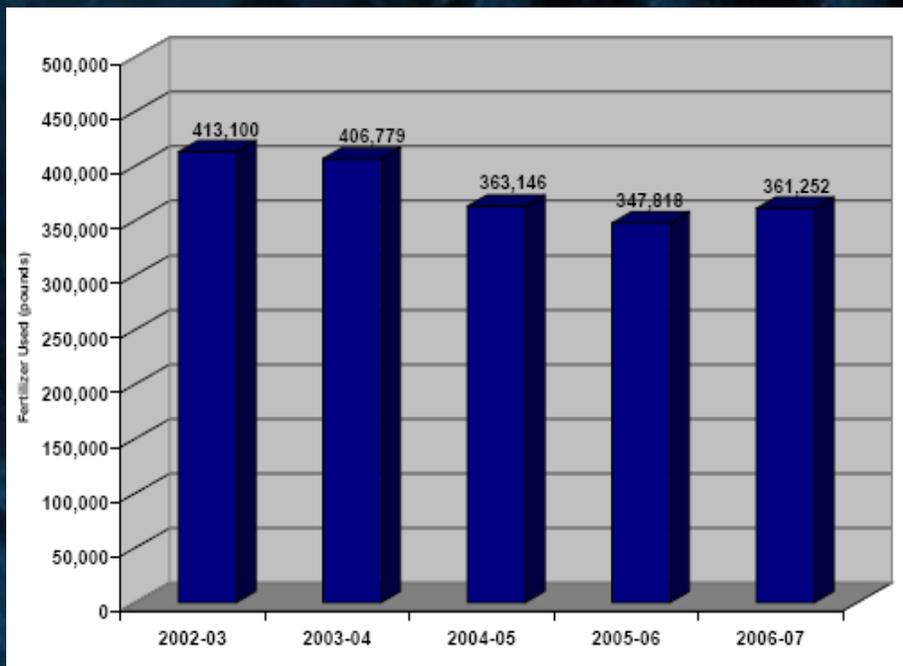

Level 3 -- Changing Behavior

Level 2 -- Raising Awareness

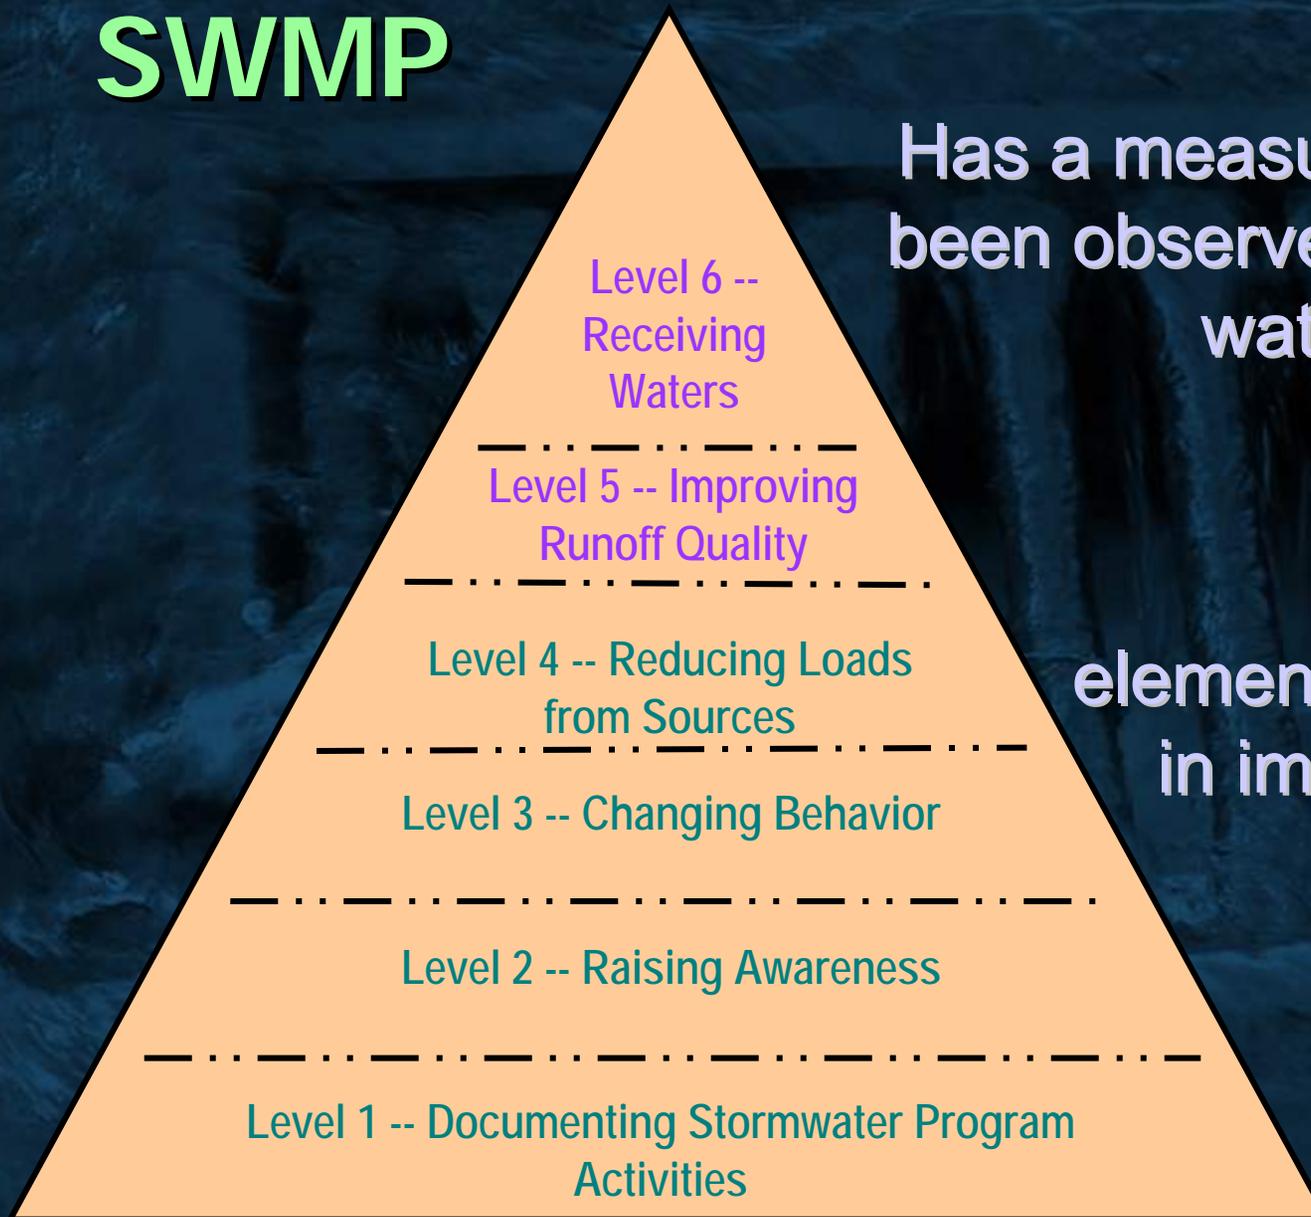

Level 1 -- Documenting Stormwater Program
Activities

Example – Outcome Level 4

- Fertilizer Application
- Street Sweeping

Outcome Levels and the SWMP

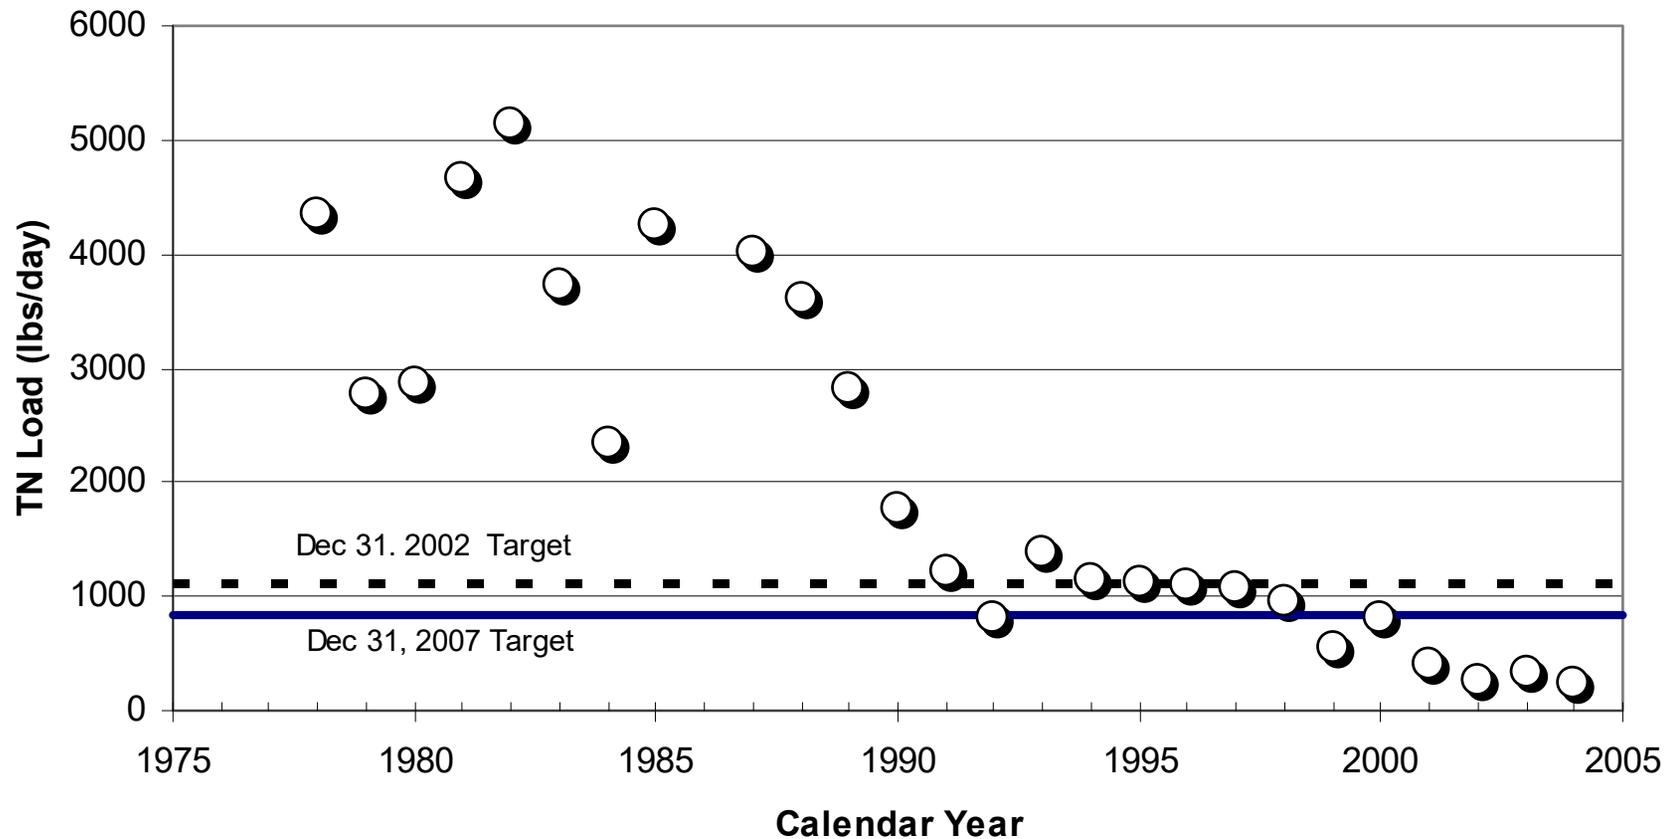

Has a measurable change been observed in receiving waters?

Does the element/program result in improved runoff quality?

Example – Outcome Level 6

Newport Bay Nutrient Reduction

Average Summertime TN Load from San Diego Creek

Visual Progress (Site 7)

1997

2007

Using the Information

4.13 Municipal Operations Program Modifications

The City evaluates the results of the annual progress report assessments as well as the experience that staff has had in implementing the program and determines if any program modifications are necessary in order to comply with Clean Water Act requirements to reduce the discharge of pollutants to the maximum extent practicable.

At this time, no major modifications are anticipated for the Municipal Operations Program during the next fiscal year.

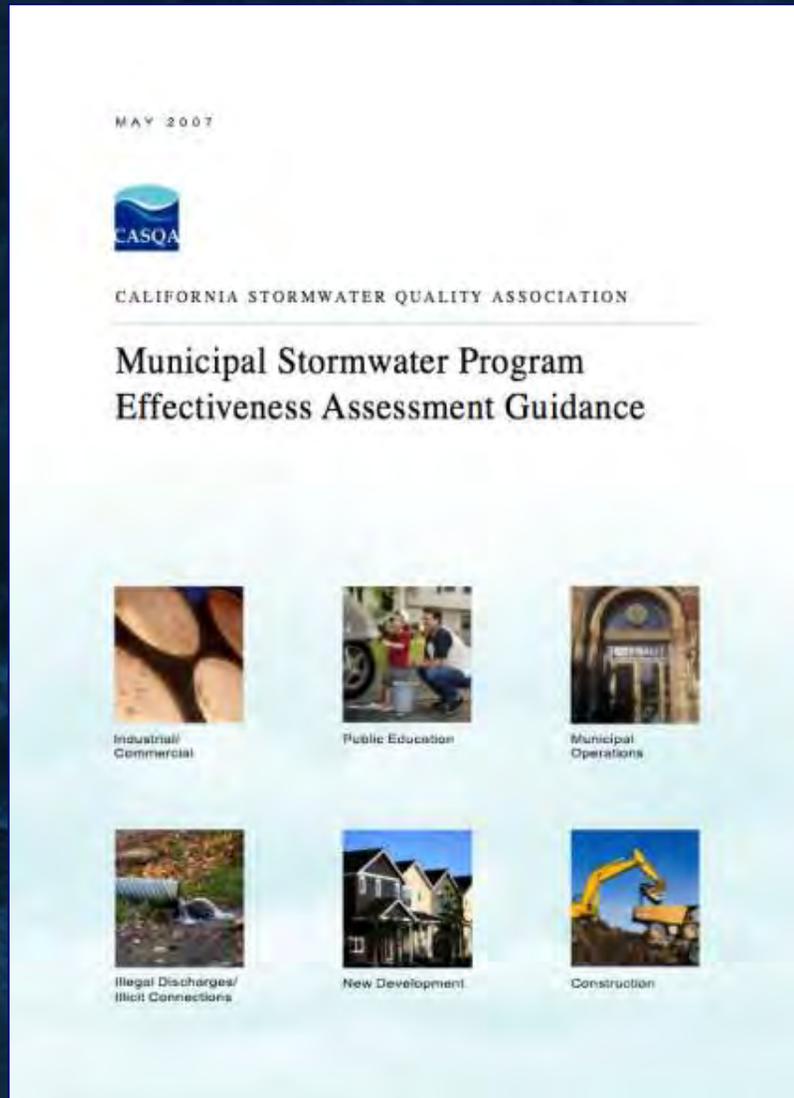

Proposed Program Modification (in ROWD):

- **Develop Model Integrated Pest Management, Pesticide and Fertilizer Guidelines into a Model Program (rather than guidelines) with implementation goals and including model contract language.**
- **Redefine IPM (pesticide use) indicators.**

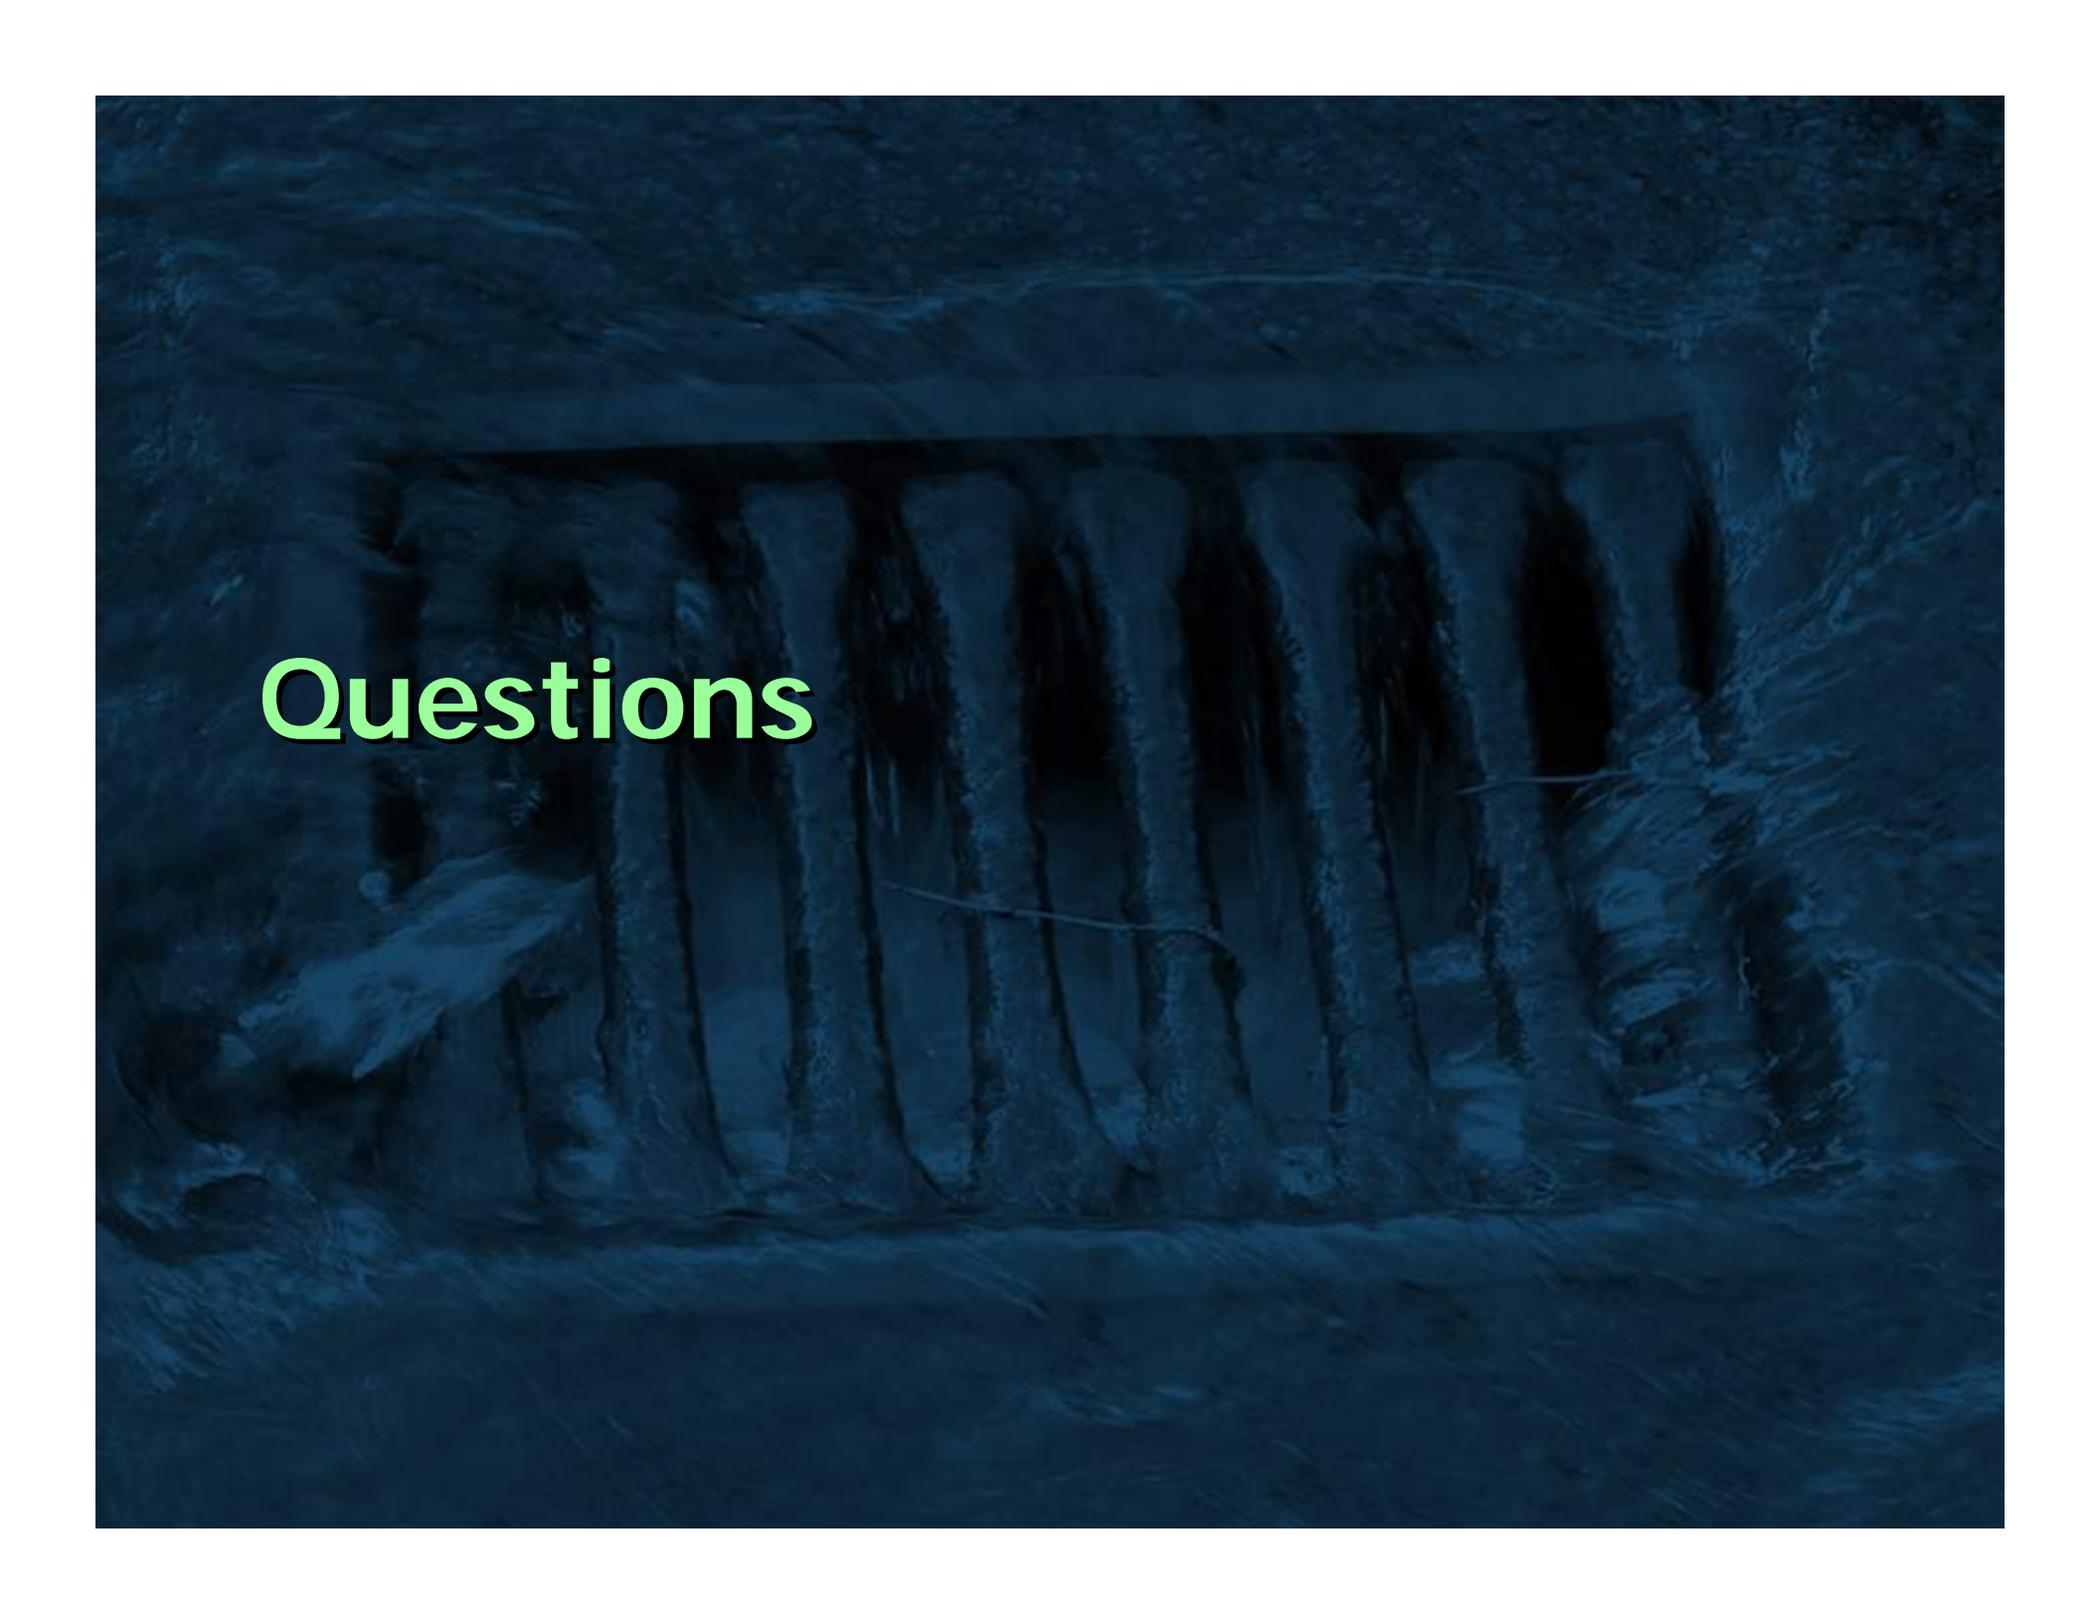

In Summary....

- Guidance Document is one approach for demonstrating effectiveness
- Assists in completing the iterative process
- Evaluates activities and impacts of program
- Can demonstrate intermediary progress towards program goals
- Approach is still evolving – stay tuned

Executive Summary

ES.1. Introduction (Section 1)

Municipal Separate Storm Sewer System stormwater programs (MS4 programs) are inherently complex for a variety of reasons.

- They typically address a number of major sources within their area of jurisdiction (construction, development, residential areas, municipal operations, and industrial and commercial facilities) and have to administer the program to tens of thousands to millions of individuals, sites and/or sources.
- Due to the geographic area that the MS4 program covers, the vast number of potential pollutants, and the volumes of flows that must be addressed, the programs tend to predominately focus on the use of source control best management practices (BMPs). While treatment controls are an important part of the MS4 program, managers often find themselves seeking to bring about the broad-scale implementation of many small controls by third parties.
- The flows in an MS4 are transported via both manmade and natural, open systems. The ability to measure, modify, or control MS4 discharges is complicated by the co-mingling of both anthropogenic and natural flows and pollutants within these systems. In addition, MS4s are often impacted by a number of non-point sources such as groundwater seepage, wind-blown and directly-deposited materials, and aerial deposition.

Despite these and other challenges, stormwater program managers find themselves facing increasing pressure to demonstrate the effectiveness of their programs, often with little guidance on how to do so. Without the specific knowledge or the tools needed to do so, stormwater managers can be faced with a perception that their programs are inadequate or failing.

Effectiveness assessment consists of the methods and activities that managers use to evaluate how well their programs are working and to identify modifications necessary to improve results.

The primary purpose of this Guidance Document is to establish specific “how to” guidance with examples for managers in planning and assessing their MS4 programs. It approaches effectiveness assessment as an integral part of a comprehensive strategic planning process. It is designed for use by MS4 program managers involved in developing and implementing all aspects of stormwater programs, but it should also be useful to a variety of dischargers regulated under other stormwater permits and programs (e.g., construction and industrial), as well as other environmental managers with a need for guidance on management and assessment principles.

Executive Summary

A structured approach to planning and assessing stormwater programs can help managers ensure that their programs are properly targeted, determine whether intended results are being efficiently and cost-effectively achieved, relate implementation results to conditions in urban runoff and receiving waters, and, ultimately, help guide managers toward implementation strategies with the greatest opportunity for long-term success.

Table ES.1 provides an overview of the organization of this Guidance Document, and briefly describes the purpose of each section.

Table ES.1: Organization of the Guidance Document

1.0	Introduction and Purpose	Provides background on the development and use of effectiveness assessment methods and their important to stormwater program managers.
2.0	General Concepts and Principles	Introduces the main components of the program planning and assessment processes, describes their use, and defines standardized concepts and terminology used throughout the Guidance Document.
3.0	Introduction to Strategic Planning for Stormwater Management Programs	Describes a stepwise process for developing a Comprehensive Program Planning Strategy, including problem characterization, goal setting, selection of control strategies and program activities, and the establishment of methods and metrics to assess effectiveness.
4.0	Source and Impact Strategies	Applies the strategic planning process introduced in Section 3.0 to the development of Source and Impact Strategies.
5.0	Target Audience Strategies	Applies the strategic planning process introduced in Section 3.0 to the development of Target Audience Strategies.
6.0	Program Implementation Strategies	Applies the strategic planning process introduced in Section 3.0 to the development of Program Implementation Strategies.
7.0	Assessment Tools and Strategies	Applies the strategic planning process introduced in Section 3.0 to the identification of tools and strategies for conducting assessments.
8.0	Interpretation and Use of Results	Provides examples of effectiveness assessments that have been conducted by stormwater programs throughout the state.
Att. A	Glossary of Acronyms and Terms	Defines key acronyms and terms used throughout the document.
Att. B	Source Profiles	Provides additional background information on the following source categories: construction, industrial, commercial, municipal operations, and planning and land development.
Att. C	Constituent Profiles	Provides additional background information on the following common constituents: bacteria, sediment, nutrients, mercury, pesticides, and trash.

Executive Summary

ES.2. Stormwater Management Approach (Section 2.0)

This section describes the primary components of a comprehensive Stormwater Management Approach. Within these components, six types of Outcome Levels are introduced. Outcomes are the backbone of the strategic planning and assessment processes described in this document. They provide the structure and measurability needed to evaluate and improve Stormwater Management Programs over time.

For the purposes of this document, stormwater management consists of three primary components:

- **Sources and Impacts** - the physical component of the management approach, i.e., it deals with the generation, transport, and fate of pollutants and flows from the urban environment (Outcome Levels 6, 5, and 4).
- **Target Audiences** - the behavioral portion of the management approach i.e., the actions of target audiences and the factors that influence them (Outcome Levels 3 and 2).
- **Stormwater Management Programs** - the various activities that are conducted within a program (Outcome Level 1).

Starting with Level 1 (Program Activities) and moving sequentially toward Level 6 (Receiving Water Conditions), they represent a general progression of conditions that are assumed to be related in a sequence of causal relationships. While it may initially seem counterintuitive, managers will normally address the six Outcome Levels in “reverse order”

Outcomes are measurable endpoints associated with programs, people, and physical systems. They are the building blocks of the management approach described in this document.

(from Level 6 to Level 1) during planning and assessment (**Figure ES.1**). The reason for this is that, in practice, they must work backwards from measured or observed effects to try and establish their causes. **Figure ES.2** illustrates the general relationship of the three stormwater management program components listed above and the six different Outcome Levels associated with them.

Figure ES.1: The “Counterintuitive” Order of Planning and Assessment Activities

Executive Summary

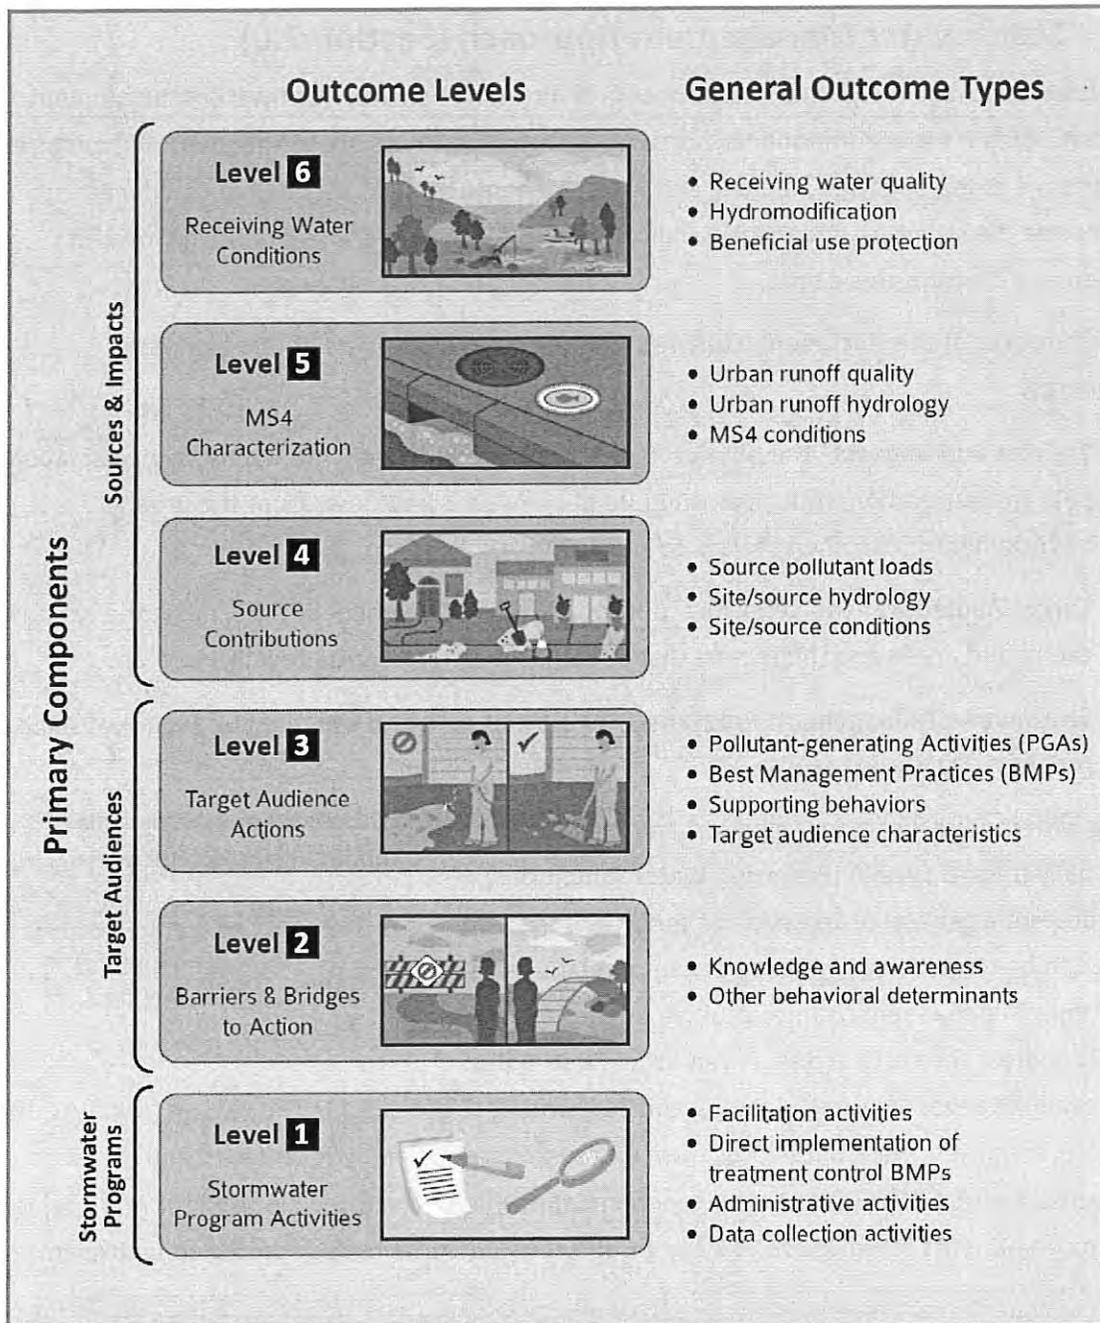

Figure ES.2: General Stormwater Management Model

This section walks the reader through each of the six individual Outcome Levels (shown in Figure ES.2) within the context of each of the primary components (**Sources and Impacts, Target Audiences, and Stormwater Management Programs**). This assists in understanding each Outcome Level both individually and in relation to the others that are influenced by it. This is critical in order for the Program to be measurable and effective in the long term.

Executive Summary

ES.3. Introduction to Strategic Planning for Stormwater Management Programs (Section 3.0)

This section applies the concepts and principles described in Section 2 to the development of a **Stormwater Strategic Plan** that will guide the development and implementation of specific stormwater management plans and programs, and establish a basis for evaluating and updating them. Strategic planning for stormwater managers is best thought of as “strategic problem solving.” Managers will identify and prioritize the problems to be addressed by their programs and develop strategies for resolving them. The general planning process described in this section provides the basis for the more detailed guidance described in the remainder of the document.

Development of a Stormwater Strategic Plan is divided into three distinct stages.

- **Planning Preparation (Stage 1)** - managers establish the basic organizational framework necessary to compartmentalize and make sense of the detailed planning tasks that follow (Section 3.2). This consists of the following steps:
 - Establishing the Strategic Plan Framework
 - Compiling Data and Information
- During **Strategic Planning (Stage 2)**, managers identify and prioritize problems to be addressed, identify specific goals for resolving them, and identify program activities needed to drive and evaluate these changes (Section 3.3).
 - **Figure ES.3** illustrates the core elements of a comprehensive strategic planning process for stormwater management programs.
 - In **Step A**, existing conditions (or outcomes) are evaluated, first very broadly and then in detail, to determine which of them constitute problems potentially requiring a management response. The tasks involved in completing this step are illustrated in **Figure ES.4**.

A **Stormwater Strategic Plan (SSP)** helps guide the development and modification of a **Stormwater Management Plan (SWMP)**. The purpose of the SSP is to systematically explore and define the strategies that will be considered and incorporated as a part of a SWMP, and to suggest how program managers might choose some options over others. In some cases, a SSP may be equivalent to, or part of, a SWMP. In others, it may constitute a separate planning document that informs SWMP development. The SSP will also meet the requirements in the Small MS4 permit for the development of a Program Effectiveness Assessment and Improvement Plan (PEAIP).

Executive Summary

- In **Step B** priority problem conditions are reviewed to determine the types of changes that will be sought and to establish timelines for achieving them. The tasks involved in completing this step are illustrated in **Figure ES.5**.
- **Step C** identifies and documents knowledge and data deficits. While this is shown as a discrete step in Figure ES.3, it's actually an integral part of the entire planning process. The tasks involved in completing this step are illustrated in **Figure ES.6**.
- **Figure ES.7** lays out the entire process for all Stormwater Management Program Components from beginning to end and identifies the sections of this document in which individual planning elements are addressed in greater detail.
- **Strategic Plan Completion (Stage 3)** provides a roadmap to guide program implementation and evaluation (Section 3.4). All Stormwater Strategic Plans will be different depending on their unique needs and circumstances, but each of the following elements should be considered for potential inclusion:
 - Source and Impact Strategies
 - Target Audience Strategies
 - Program Implementation Strategies
 - Assessment Tools and Strategies

Completing this comprehensive process will often require that a wide range of data and information be considered, sometimes beyond explicit regulatory requirements. The purpose of this process is not to create additional requirements, rather it is designed to help managers more effectively and efficiently meet existing ones.

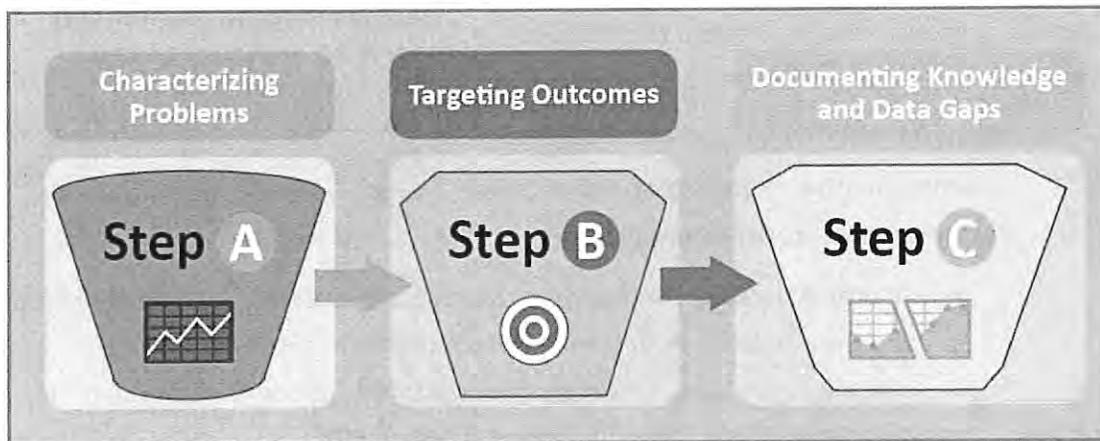

Figure ES.3: Core Strategic Planning Steps (applies to Outcome Levels 2 through 6)

Executive Summary

Step A

Characterizing Problems

During characterization, managers explore what is known about existing conditions at all Outcome Levels, determine which of them constitute problems, and develop priorities for the changes to be sought through program implementation. This work is divided into three tasks as shown and described below.

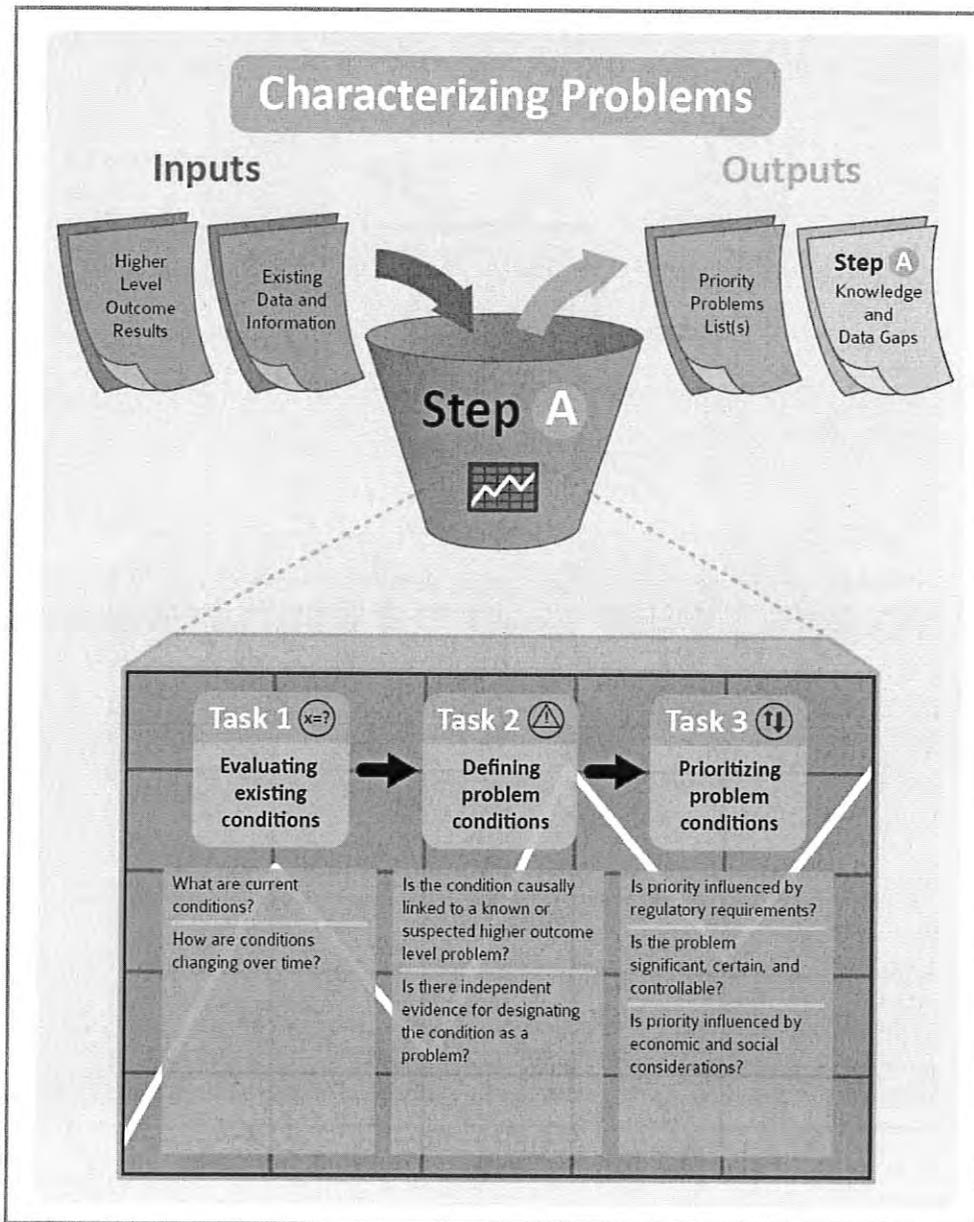

Figure ES.4: General Process for Characterizing Problems

Executive Summary

Step B Targeting Outcomes

Targeted outcomes will define what a control strategy is designed to achieve, and in turn how specific actions can be directed to facilitate these changes.

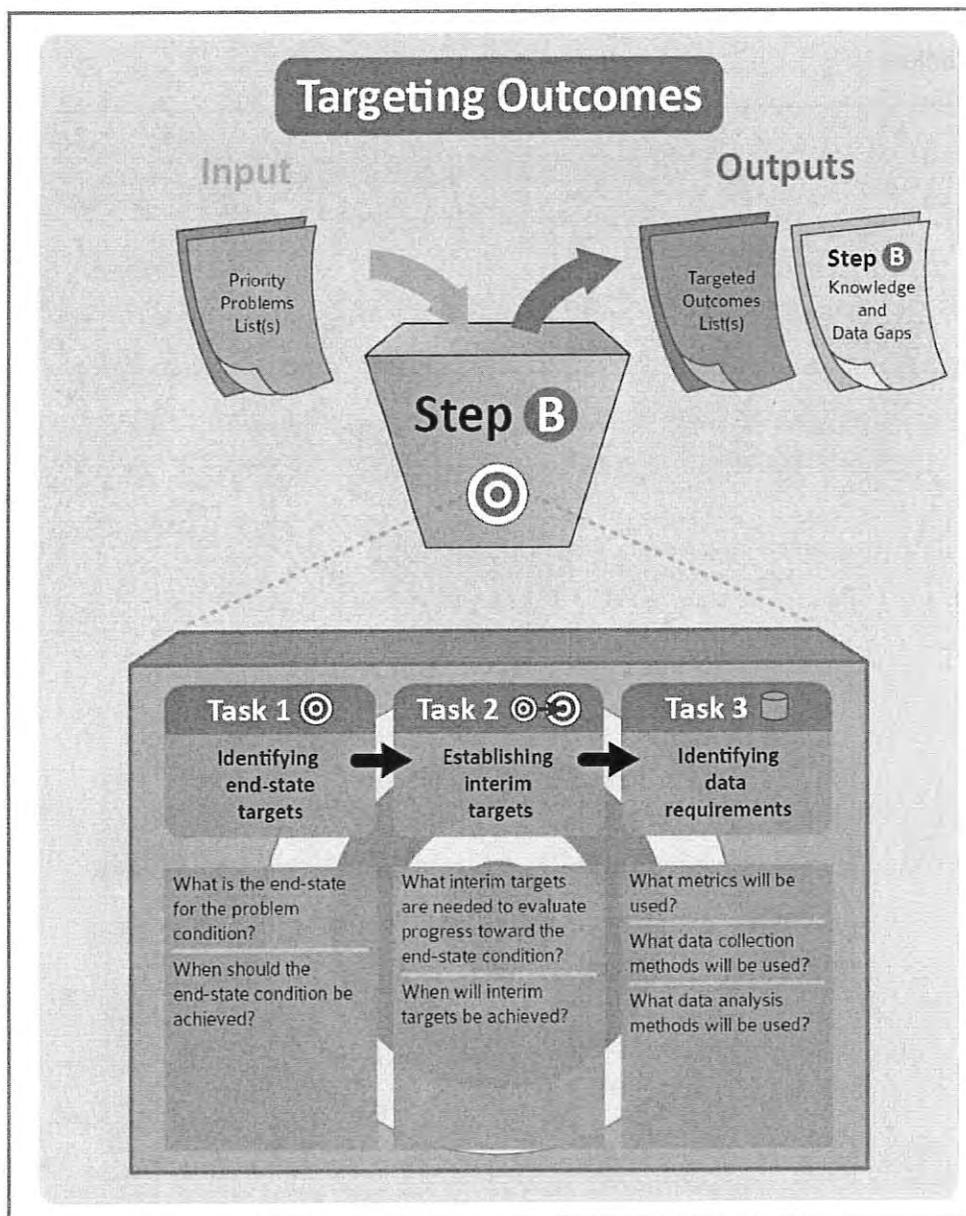

Figure ES.5: General Process for Targeting Outcomes

Executive Summary

Step C Documenting Knowledge and Data Gaps

Knowledge and data gaps should be documented throughout the planning process, and strategies developed for addressing critical gaps through targeted data gathering initiatives.

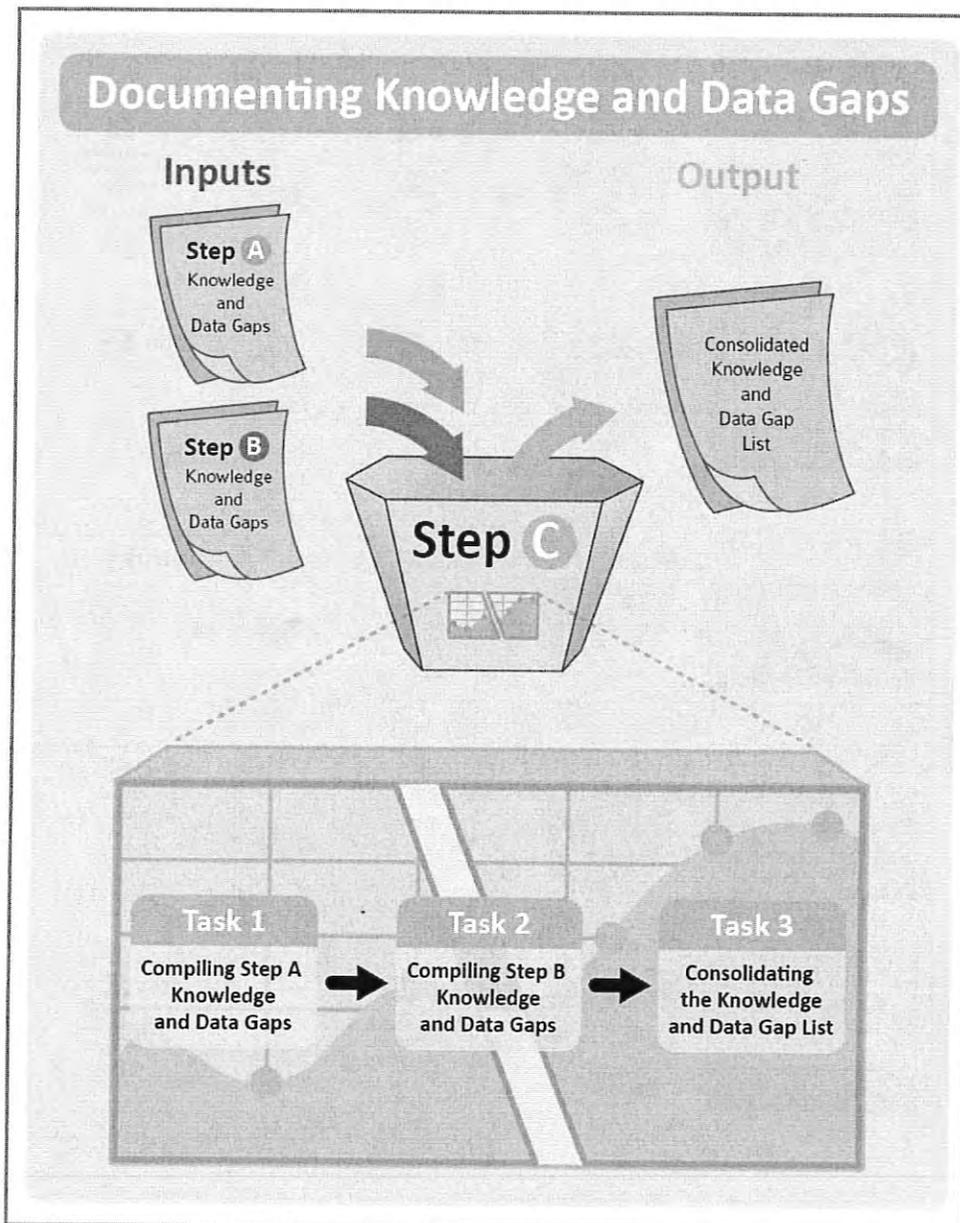

Figure ES.6: General Process for Consolidating Knowledge and Data Gaps (Step C)

Executive Summary

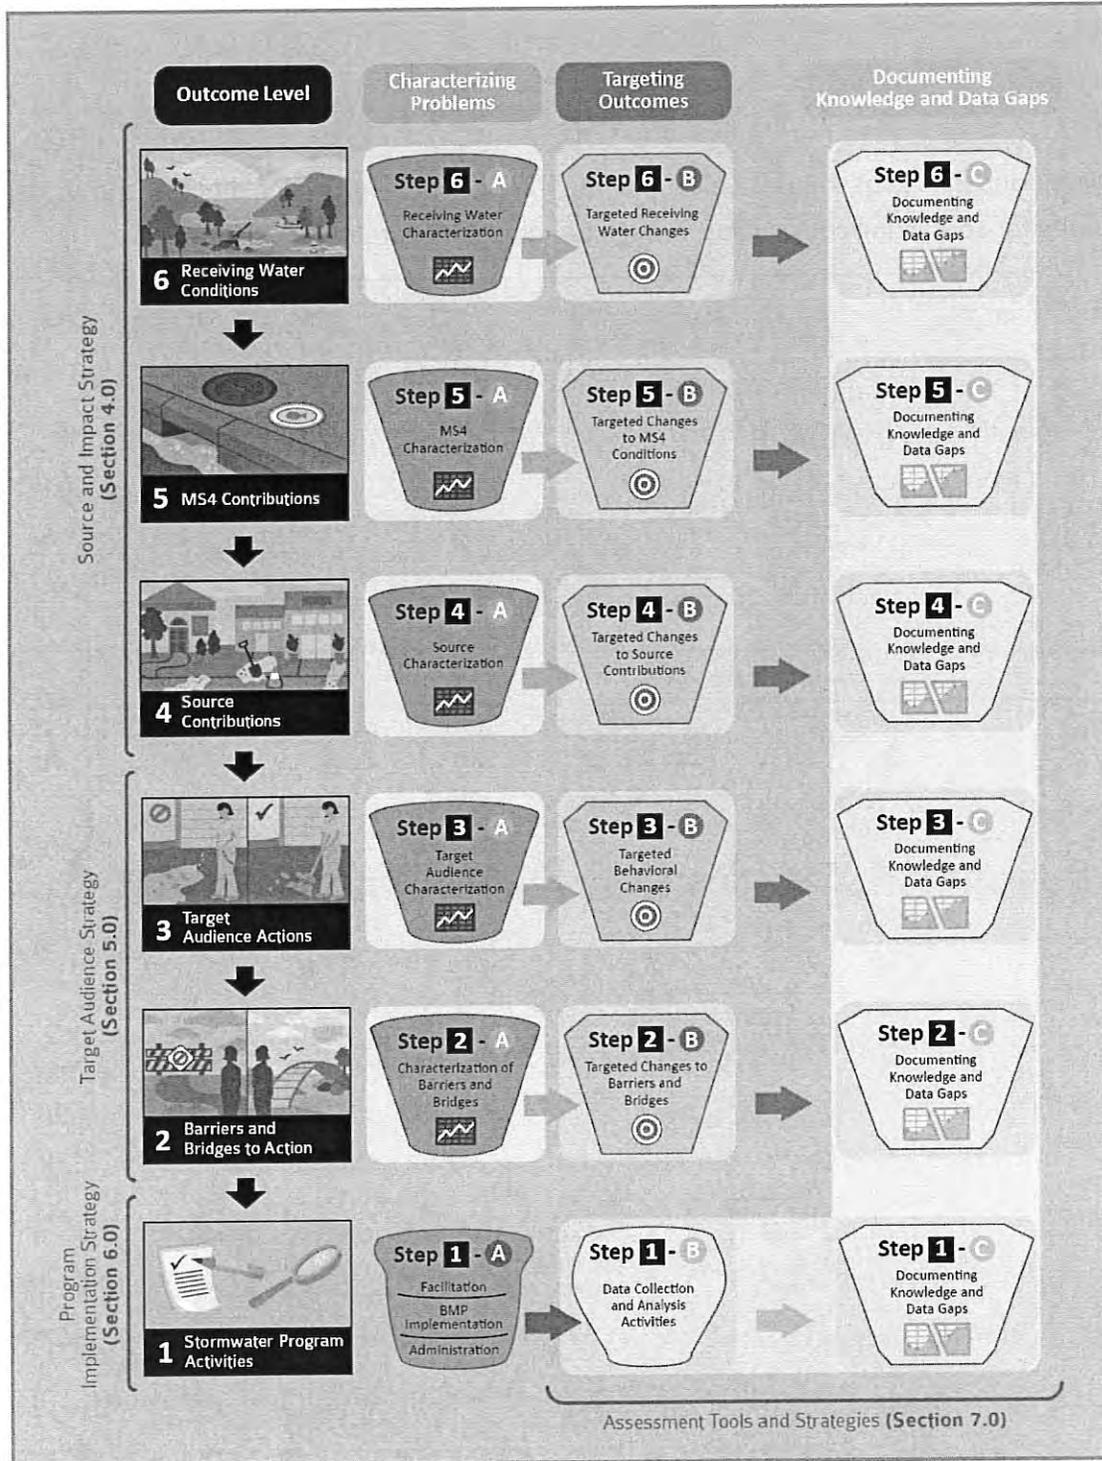

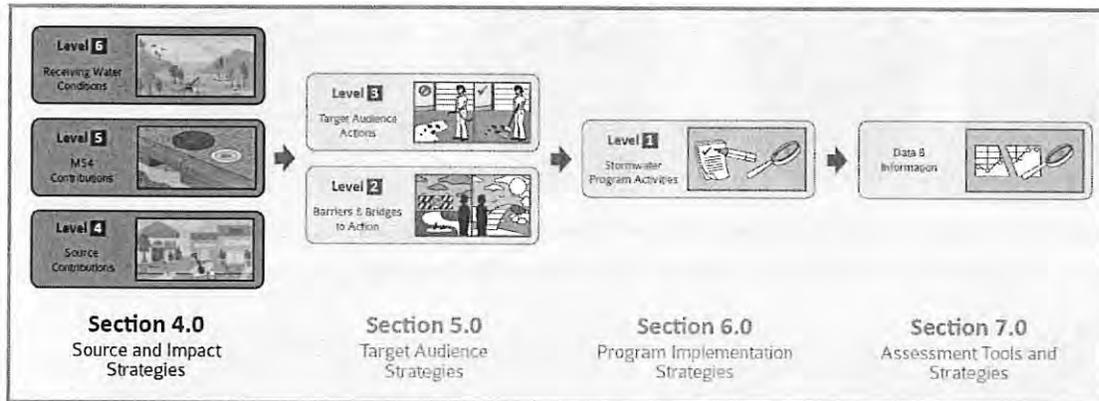

Figure ES.7: Strategic Planning Process Overview

Executive Summary

ES.4. Source and Impact Strategies (Section 4.0)

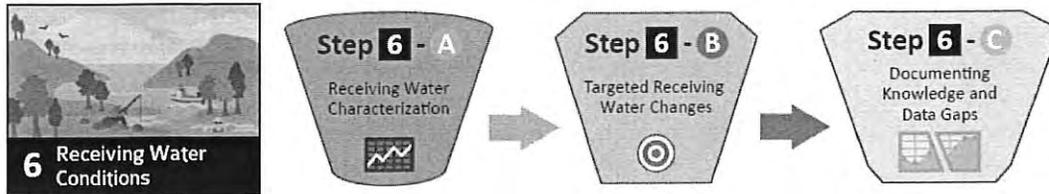

This section describes the development of **Source and Impact Strategies**. This section utilizes the strategic planning process presented in Section 3.0 to identify and prioritize sources of pollutants and flows to receiving waters. It begins with the evaluation of receiving water problems, and then “works back” toward potential contributing sources via MS4s and associated drainage areas. Following this approach, source priorities can be identified in response to demonstrated priority water quality impacts. However, since receiving water and MS4 impacts are often not well-documented, “preventive” approaches that focus primarily on the potential of sources to generate flows or pollutants must also be considered.

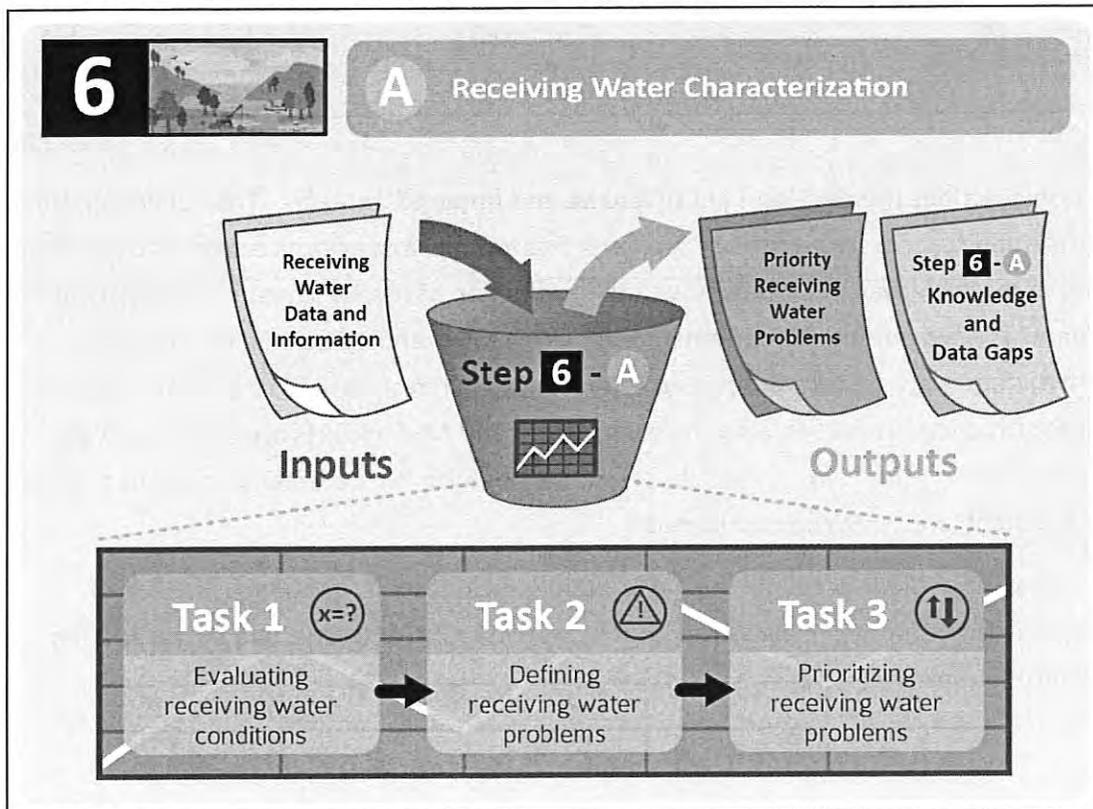

The development of the Source and Impact Strategies includes the following approach to evaluating outcomes for Receiving Water Conditions, MS4 Contributions, and Drainage Area and Source Contributions.

Executive Summary

Outcome Level 6: Receiving Water Conditions

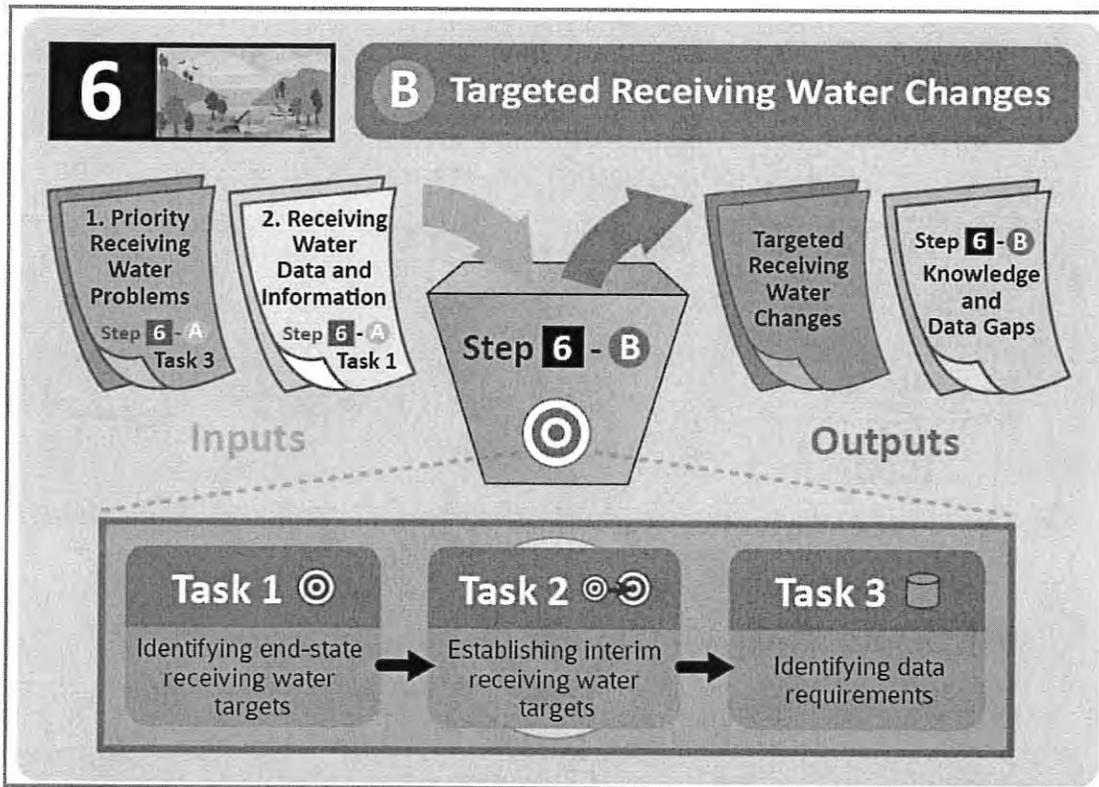

- In **Step 6-A**, managers review existing data and information to evaluate conditions in receiving waters. Initial results are then narrowed to focus on priority problem conditions.

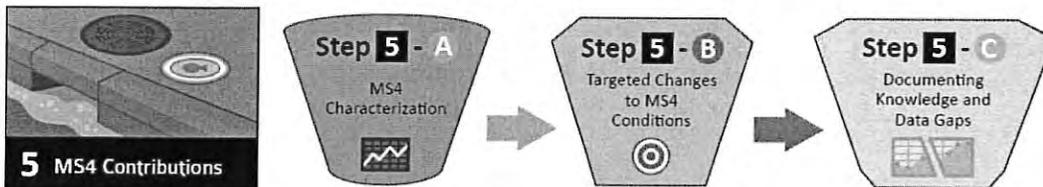

- **Step 6-B** focuses on defining the changes that will be sought in these conditions over time.

Executive Summary

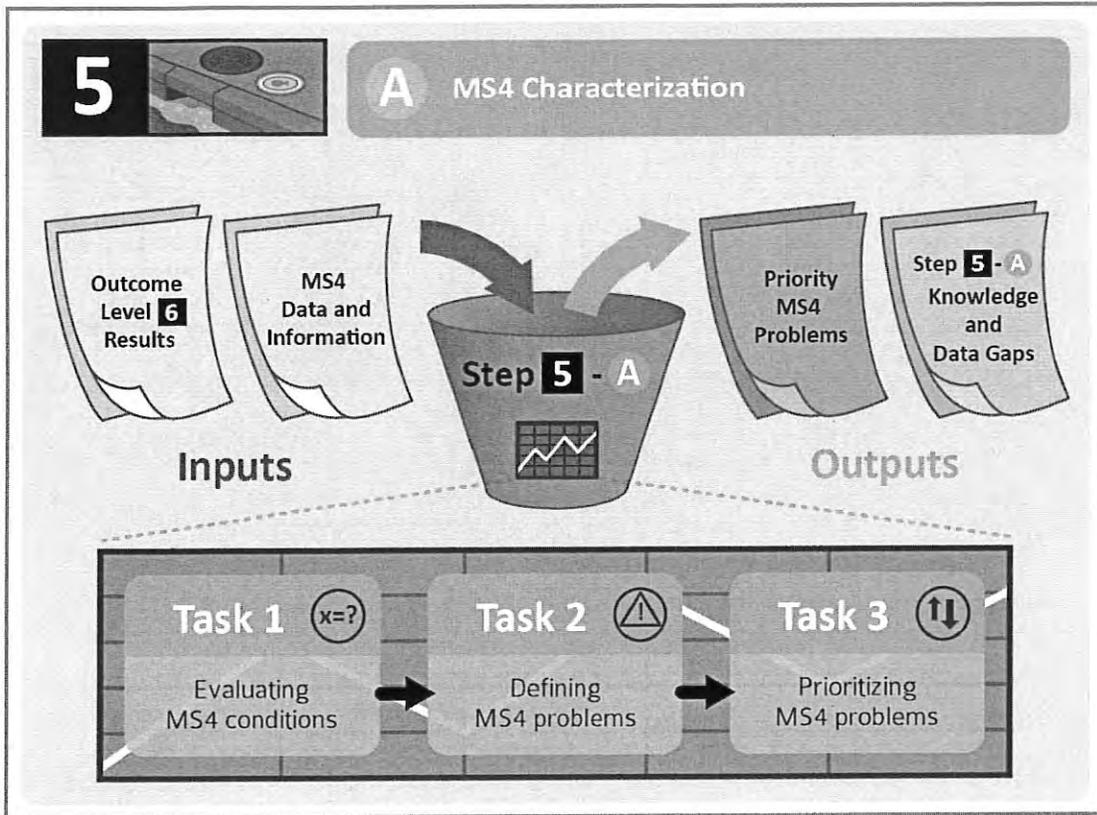

- Finally, **Step 6-C** identifies the knowledge and data gaps discovered along the way, so that future data collection initiatives can be directed toward resolving them.

Outcome Level 5: MS4 Contributions

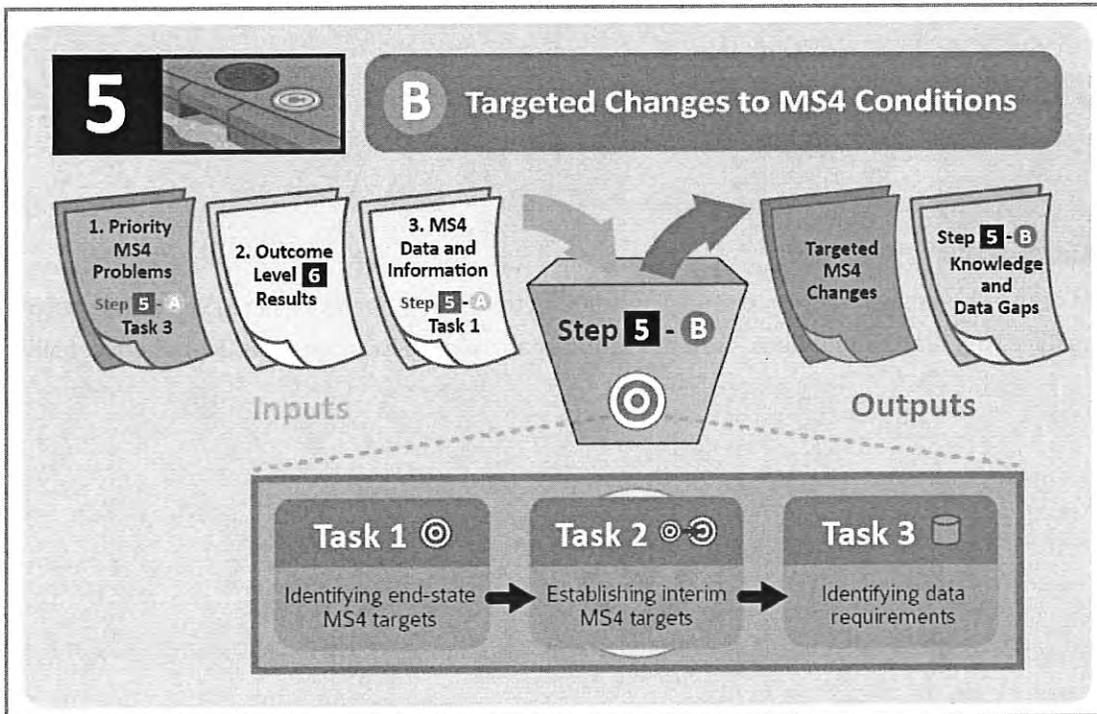

- In **Step 5-A**, managers review existing information to evaluate conditions in MS4s and contributions to Receiving Water Conditions. Results are then narrowed to focus on priority problem conditions.

Executive Summary

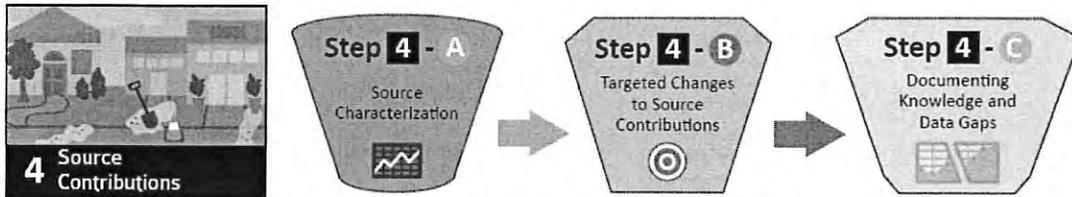

- Step 5-B focuses on defining the changes that will be sought in these conditions over time.

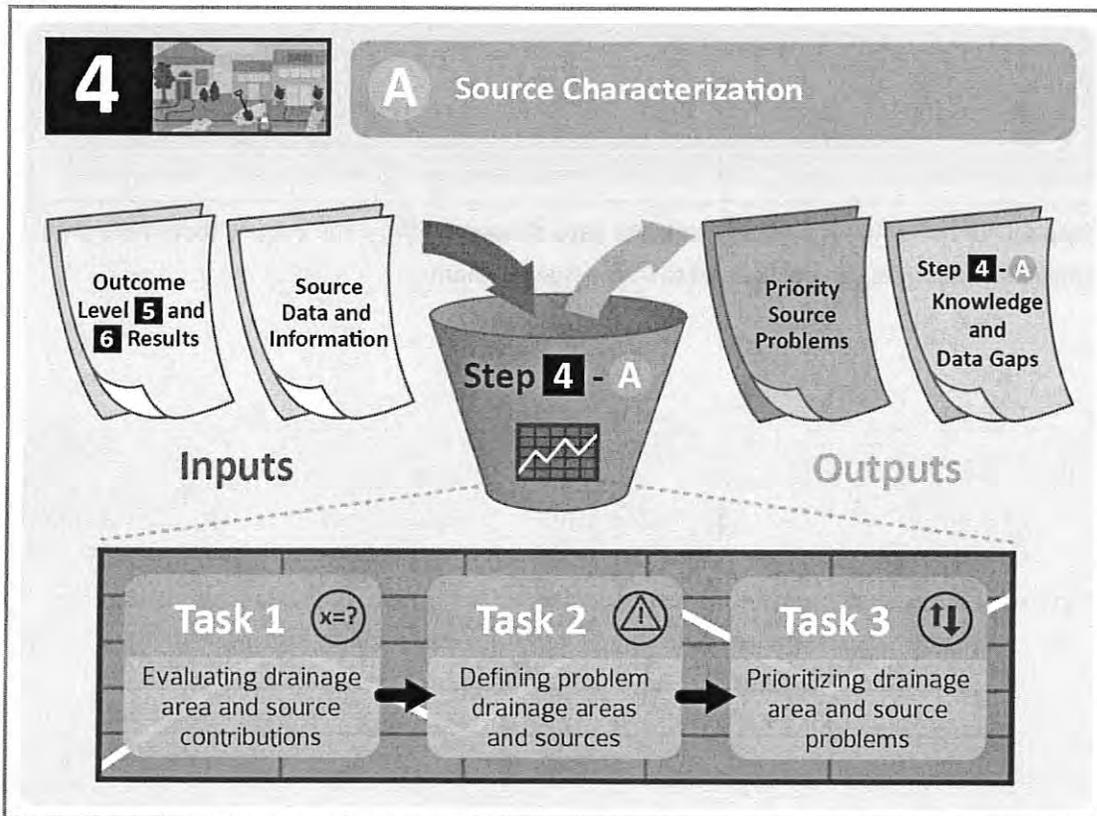

Executive Summary

- **Step 5-C** identifies the knowledge and data gaps discovered along the way, so that future data collection initiatives can be directed toward resolving them.

Outcome Level 4: Source Contributions

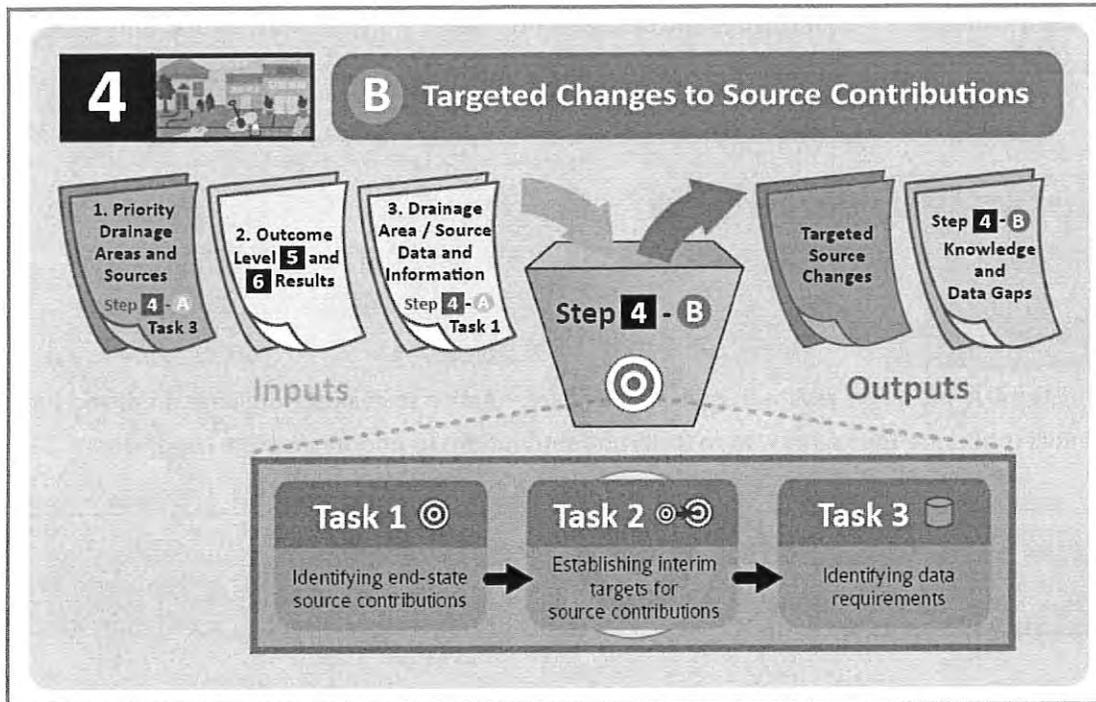

- In **Step 4-A**, managers review existing data and information to evaluate drainage areas and sources. Initial results are then narrowed to focus on contributions to priority problem conditions.

- **Step 4-B** focuses on defining the changes that will be sought in these conditions over time.

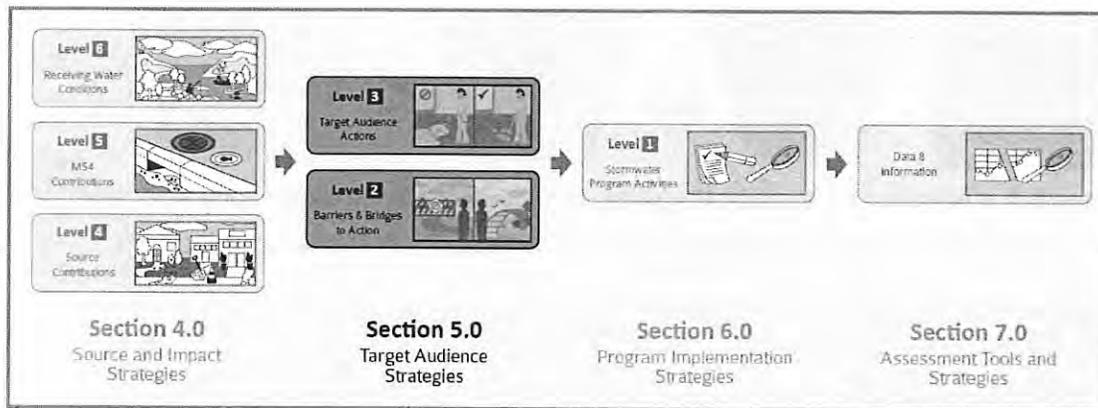

Executive Summary

- **Step 4-C** identifies the knowledge and data gaps discovered along the way, so that future data collection initiatives can be directed toward resolving them.

Executive Summary

ES.5. Target Audience Strategies (Section 5.0)

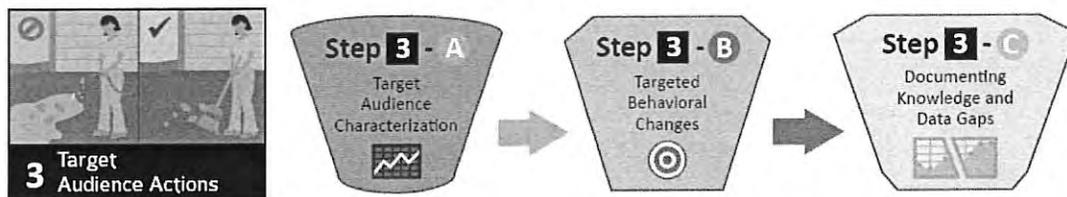

This section describes the development of **Target Audience Strategies**. Following the identification and prioritization of source contributions, as described in Section 4.0, target audience planning addresses Outcome Levels 3 and 2. Managers will focus on identifying the people that are responsible for these contributions, and then on characterizing the specific behaviors attributable to them. Ultimately, they will need to know how people should be acting differently and develop a clear understanding of the factors that may be standing in the way of desired changes.

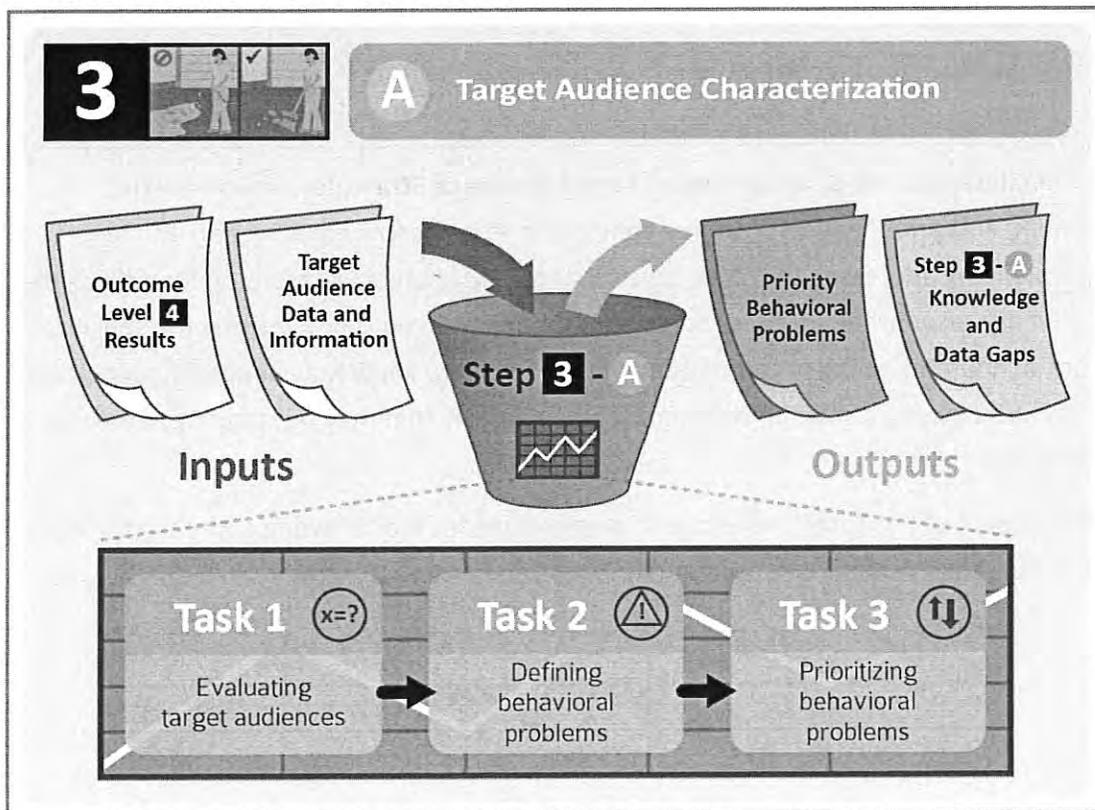

The development of the Target Audience Strategies includes the following approach for evaluating outcomes for Target Audience Actions and Bridges and Barriers to Action.

Executive Summary

Outcome Level 3: Target Audience Actions

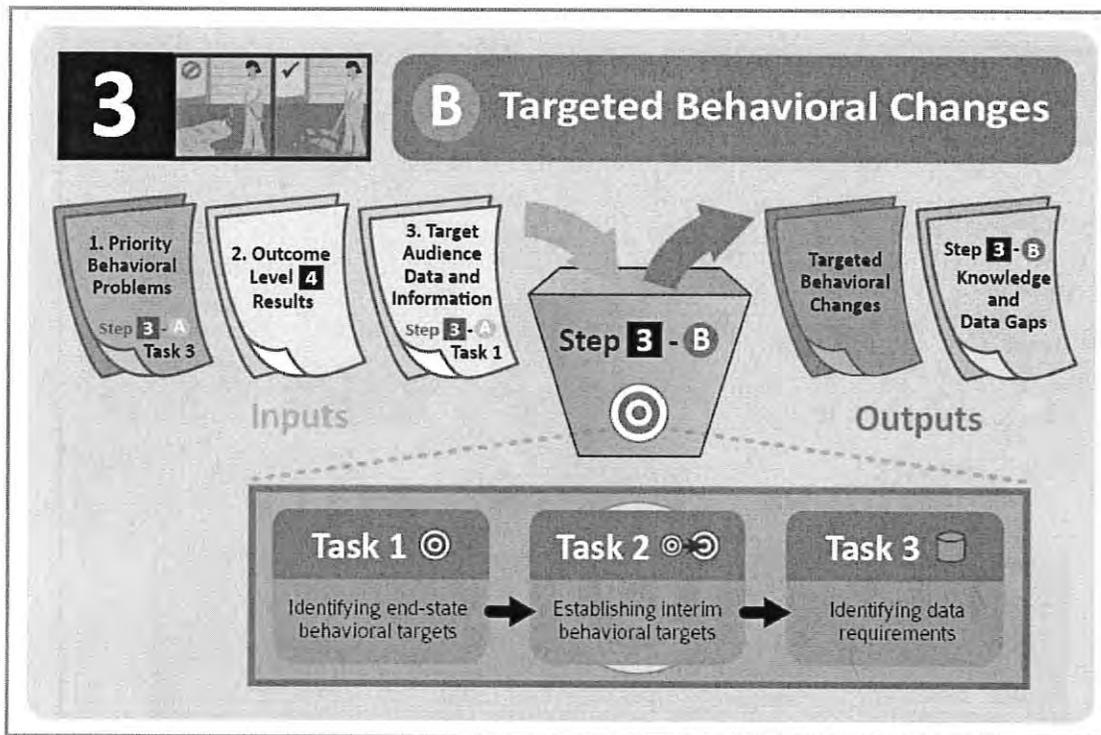

- In **Step 3-A** managers will identify, prioritize, and learn about the target audiences and their actions that may be responsible for the identified priority source contributions.

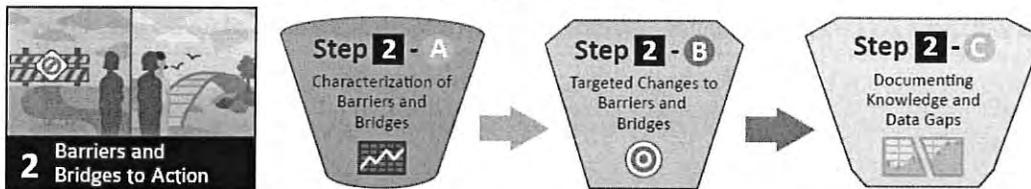

- Once priority target audiences and behaviors are identified, specific changes in them will be targeted in **Step 3-B**.

Executive Summary

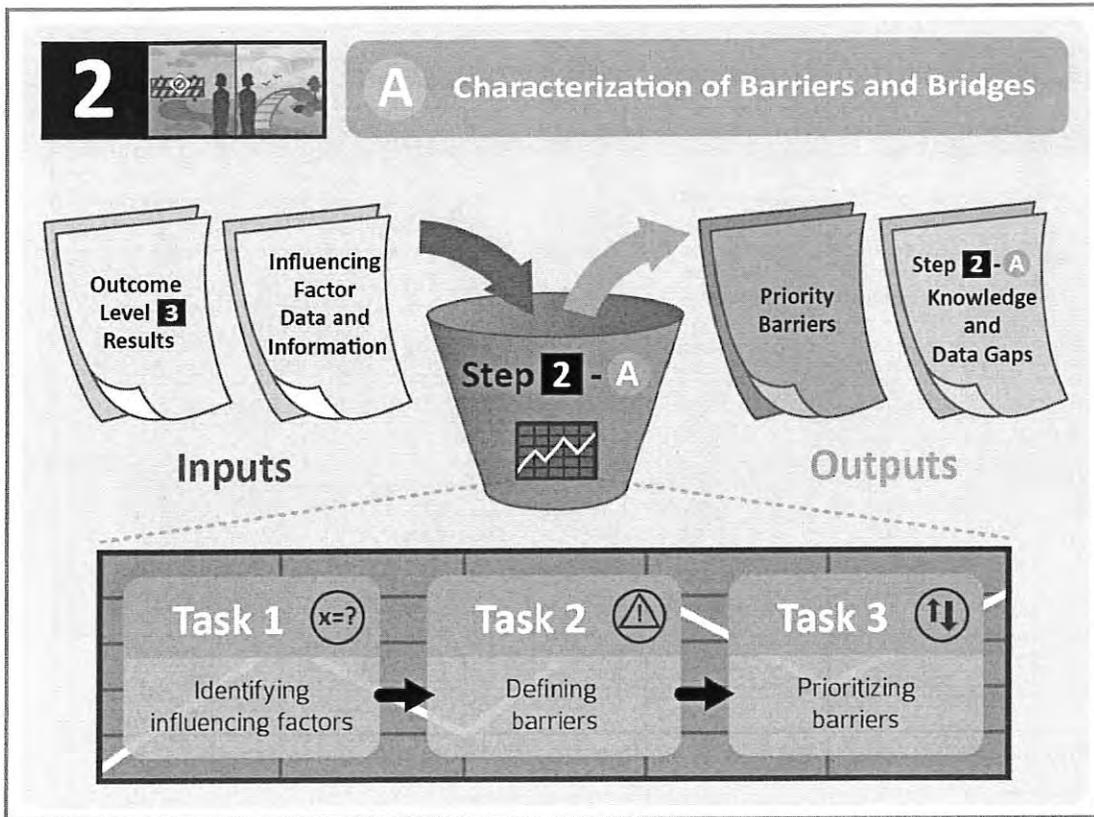

- Knowledge and data gaps will be summarized and documented in **Step 3-C**.

Outcome Level 2: Barriers and Bridges to Action

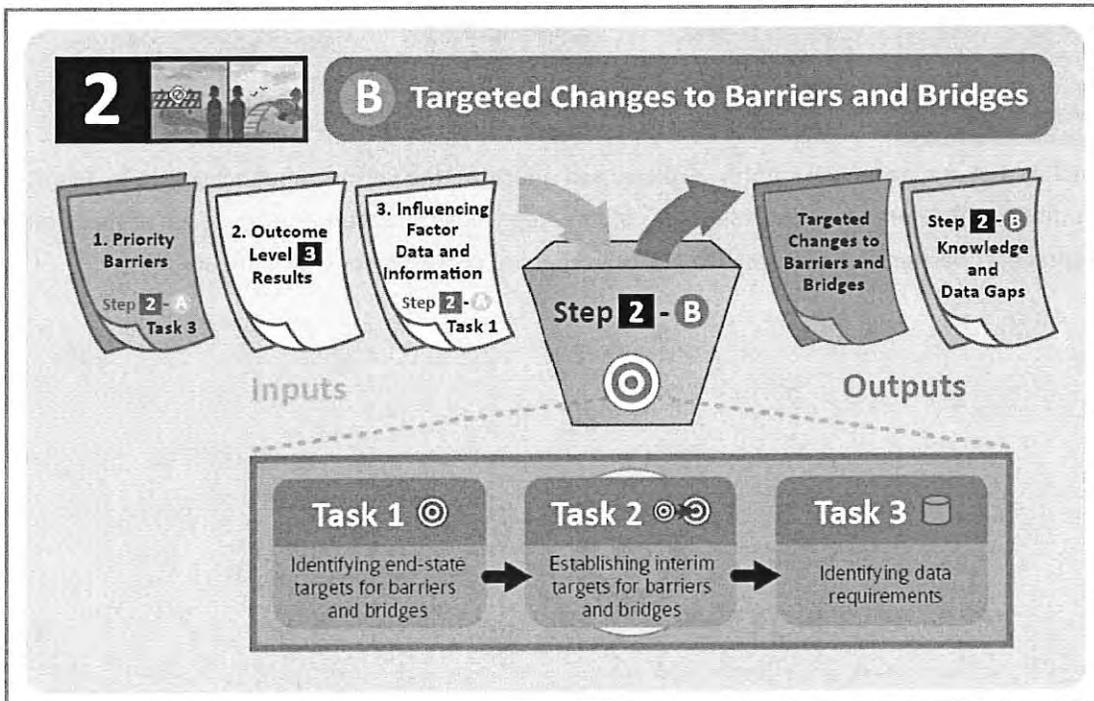

- In **Step 2-A** managers will identify, explore, and prioritize, the factors influencing priority target audience behaviors. An important focus of this step will be to determine how each of these might represent “**barriers**” or “**bridges**” to practices that are protective of water quality.

Executive Summary

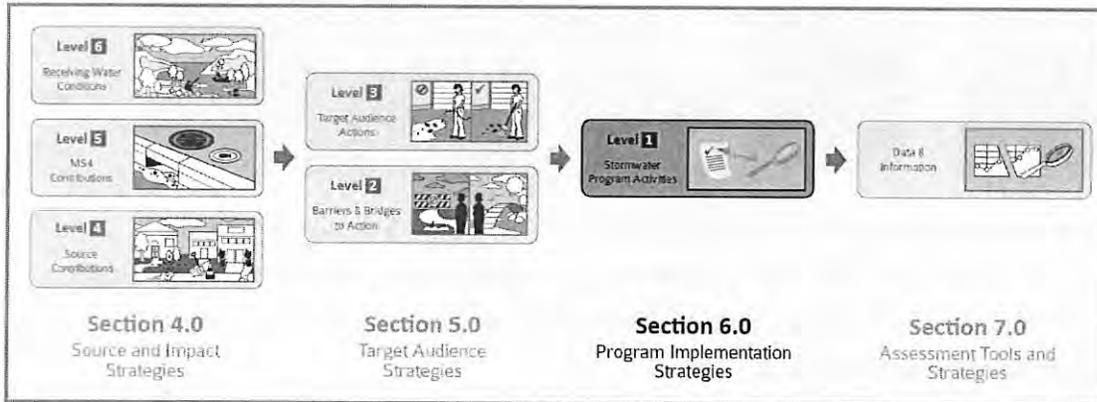

- Step 2-B will focus on targeting changes in factors that favor implementation of BMPs over PGAs.

- Finally, Step 3-C will look at the knowledge and data gaps discovered along the way.

Executive Summary

ES.6. Program Implementation Strategies (Section 6.0)

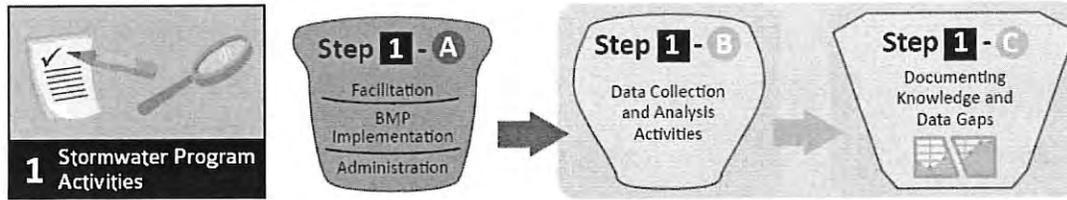

This section describes the development of **Program Implementation Strategies**. Following the completion of Target Audience Strategies, as described in Section 5.0, program implementation planning addresses Outcome Level 1. Managers will consider the target audiences, critical behaviors, and barriers and bridges already identified to develop stormwater program implementation strategies for bringing about targeted changes. Other activities needed to support general program operation and to obtain feedback for evaluating success are also considered.

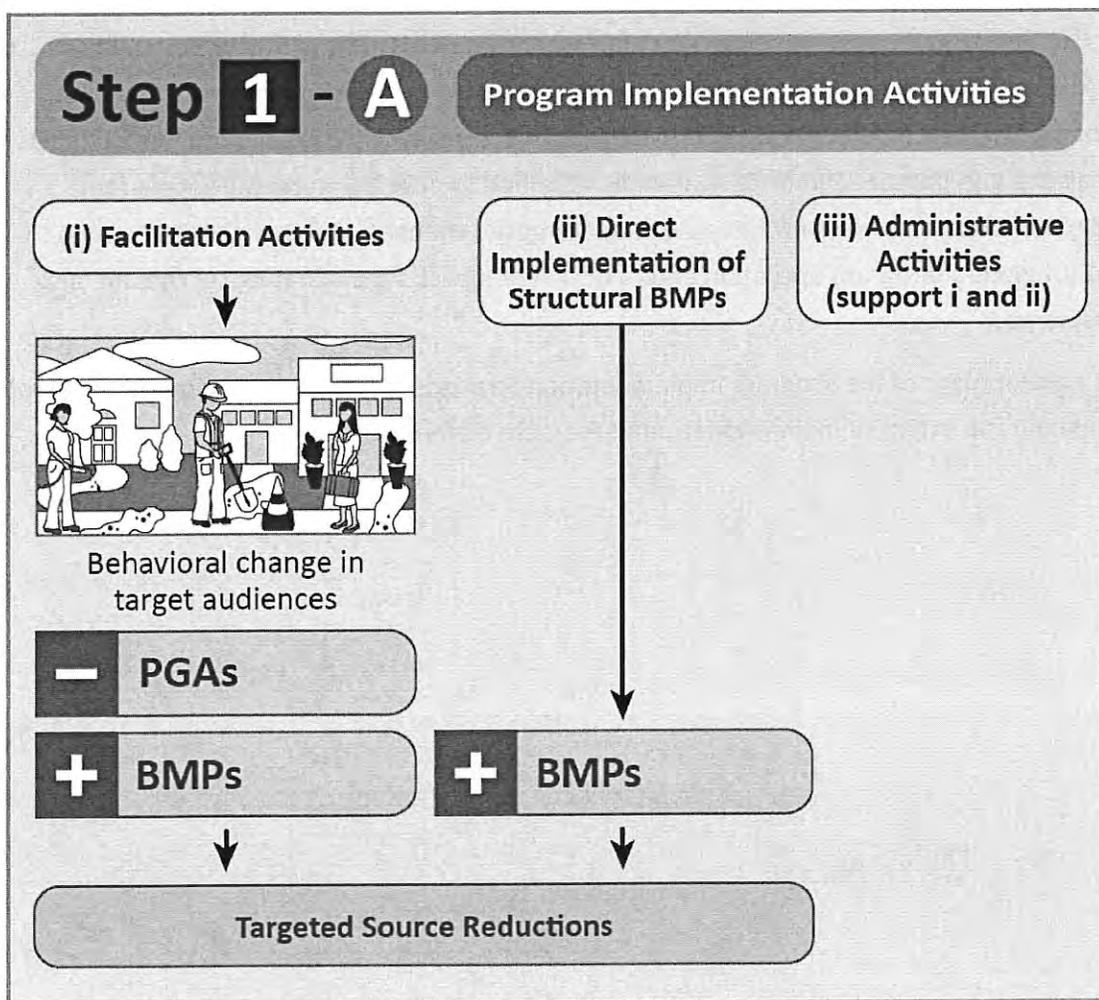

The development of the Program Implementation Strategies includes the following steps for evaluating the extent of implementation of Program elements.

Executive Summary

Outcome Level 1: Stormwater Program Activities

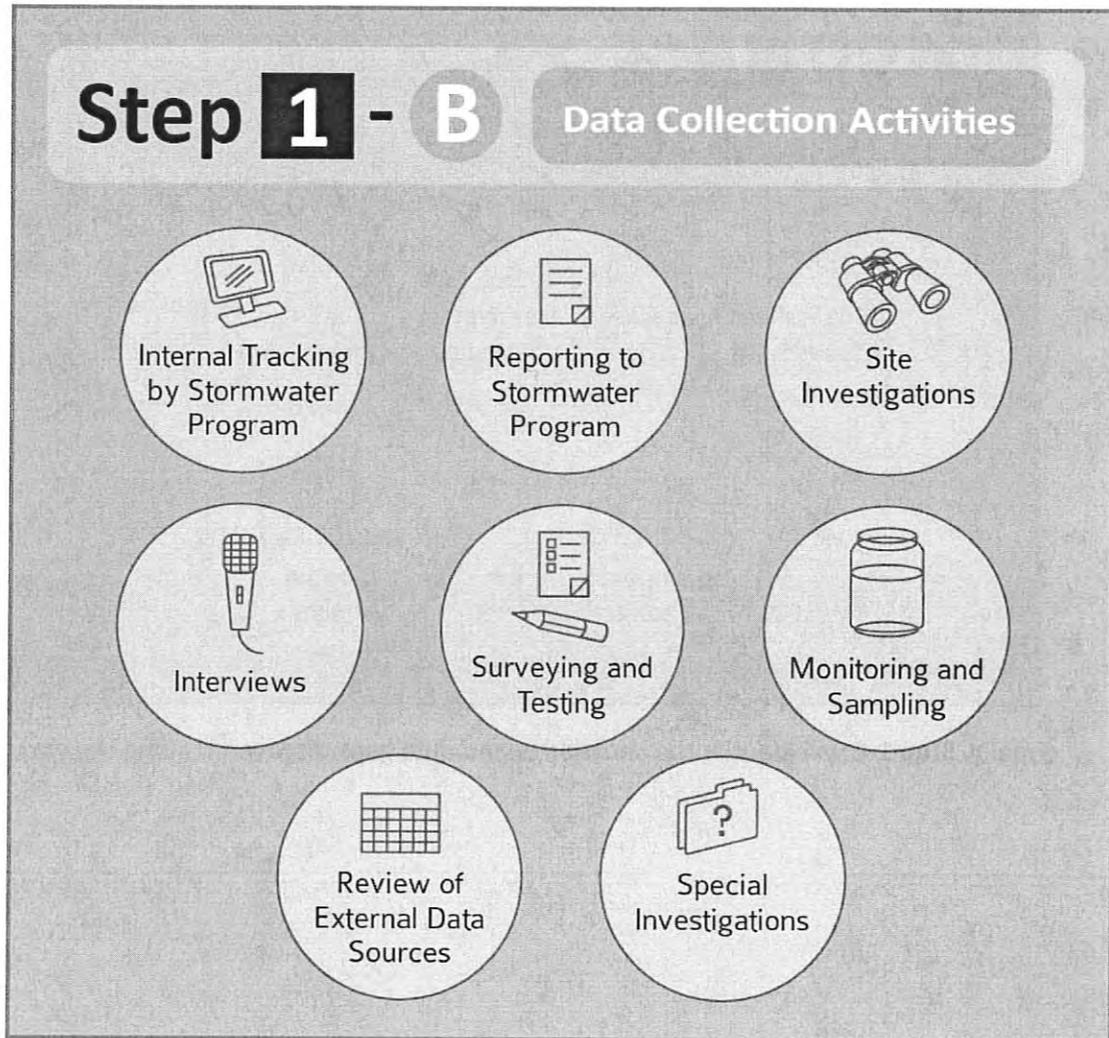

- In **Step 1-A** managers will identify the activities to be targeted during program implementation. This will initially entail the development of strategies to modify target audience behaviors, but BMPs that can be implemented directly by the stormwater program will also be identified.

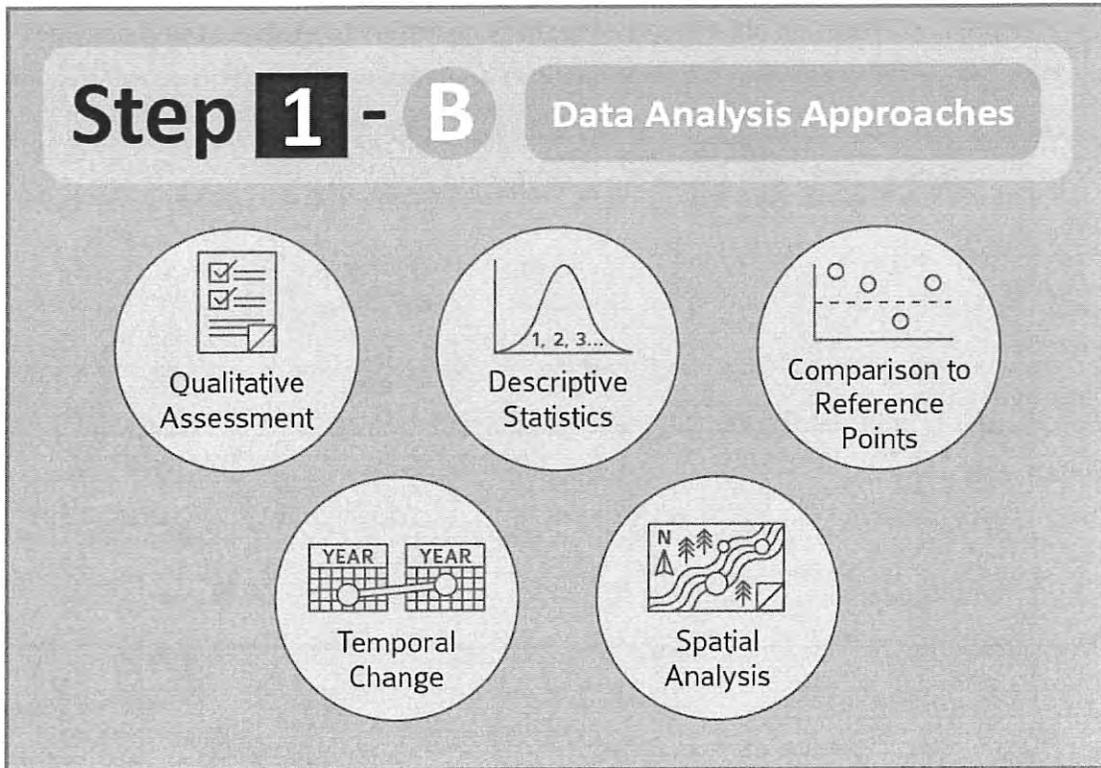

Executive Summary

- Step 1-B will focus on obtaining the feedback necessary to evaluate these activities.

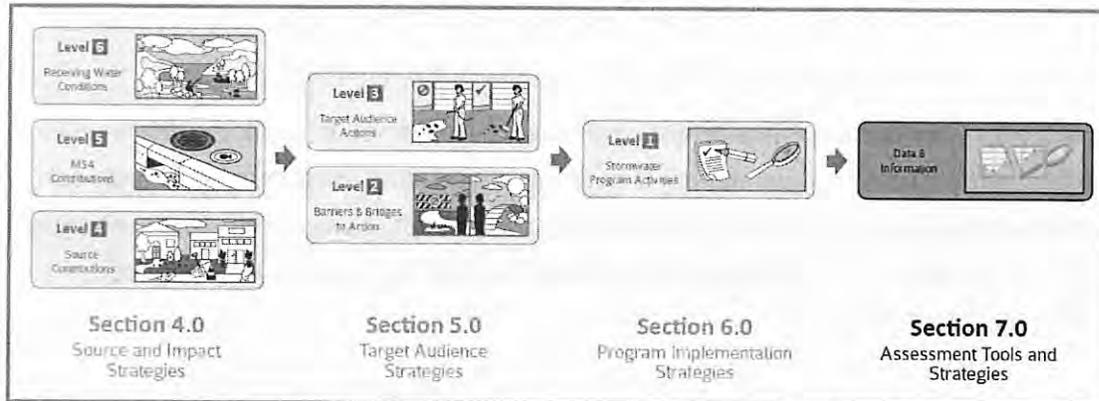

Executive Summary

- Finally, **Step 1-C** will identify the knowledge and data gaps discovered along the way.

Executive Summary

ES.7. Assessment Tools and Strategies (Section 7.0)

This section describes the development of **Assessment Tools and Strategies**. Up to this point, managers will have focused on a comprehensive planning process aimed at identifying a variety of specific measurable outcomes that will define success, guide the implementation of programs, and provide the structure and measurability needed to support a meaningful adaptive management approach.

This section builds on the targeted outcomes identified in Sections 4.0 through 6.0 to provide:

- **Data Collection and Assessment Design and Implementation:** includes monitoring and study design frameworks and approaches to data collection and analysis for each of the Outcome Levels.
- **Application of Data Collection and Program Assessment Methods:** this section provides examples of how to apply these data collection and analysis and assessment methods and approaches to outcome types such as MS4 water quality, source contributions to pollutant loading, and behaviors changes for compliance at construction sites.
- **Adaptive Management:** the results from the Assessment Strategies will provide feedback to assess progress and original assumptions in order to adapt and modify the program to more effectively reach the interim and end-state goals.

Assessment Strategy is the approach that will be used to collect and analyze data to track and assess the interim targets for each of the outcome levels. This strategy is part of an adaptive management approach that provides feedback into the program to improve its' effectiveness.

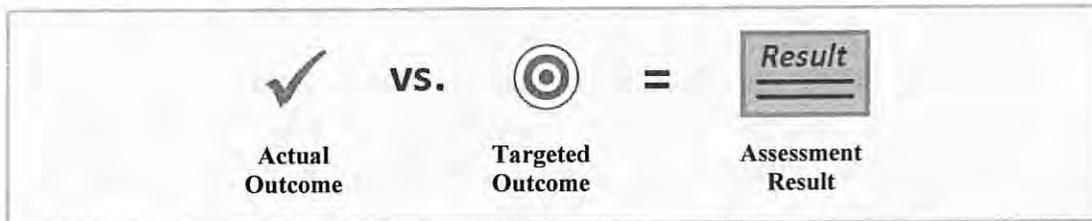

The Assessment Strategy will, based on the identified targeted outcomes, metrics and timelines from each Outcome Level, identify the methodology for data collection and analysis.

Executive Summary

ES.8. Interpretation and Use of Results (Section 8.0)

This section describes how analyses can be conducted, reported out on, and used to improve the stormwater program. Examples of effectiveness assessment are also provided.

Once the strategy for the program effectiveness assessment has been developed, the stormwater program manager should identify the data that is necessary to conduct the assessments and ensure that the approach and infrastructure for the data collection is in place. This step is critical in order to be able to conduct the desired analyses and report out on the goals and/or metrics identified within the PEA strategy.

The analyses can assist program managers in assessing progress in meeting intermediary goals, long-term goals, and identifying programmatic changes that may be necessary in order to obtain a stormwater program goal. In addition, the results may be presented to interested parties so that they may understand the benefits of the stormwater program.

Once an effectiveness assessment has been conducted, stormwater program activities should be modified, as needed, based on the results of the assessment. Modifications may include:

- Improving upon areas that did not accomplish goals;
- Expanding upon efforts that proved to be effective;
- Discontinuing efforts that may no longer be productive; or
- Shifting priorities to make more effective use of resources.

Since the development and implementation of a stormwater program is a phased effort and higher Outcome Levels often require relatively large amounts of data over a period of years, many programs will initially assess the effectiveness of the lower Outcome Levels. However, assessments should be conducted at the highest Outcome Level supported by the data, and program managers should strive to address the higher Outcome Levels as soon as possible.

The rest of the section includes examples of various effectiveness assessments that have been conducted by municipal stormwater programs throughout the state. These examples will assist other stormwater program managers in determining what metrics they may want to utilize for their program and/or how they may conduct their analyses and use the results.

EXECUTIVE SUMMARY

In recognition of the pervasive effects of hydromodification (i.e. alteration of runoff patterns associated with change in land use that result in change in physical channel conditions) on southern California streams, many municipalities are now required to develop hydromodification management programs. Monitoring the effectiveness of these programs is critical because hydromodification management is in its infancy, and there is much to be learned from early efforts. This document is intended to provide a framework to assist state agencies, local jurisdictions, and municipal stormwater permittees in developing detailed hydromodification monitoring plans to address specific management and reporting needs.

Monitoring the effects of hydromodification is challenging. Physical changes associated with changes in runoff are difficult to assess because they can result from a combination of contemporary land-use changes, legacy land practices (e.g. grazing), and stochastic events (e.g. floods and fires). Furthermore, channel adjustments can occur dramatically and rapidly after extended periods of apparent stability and can vary over small distances. Separating out the effects of human activity from natural cycles of channel evolution further complicates hydromodification monitoring and requires much longer term monitoring than traditional water quality programs.

Given the need for long-term commitment and investment, we propose a tiered approach to hydromodification monitoring. This tiered approach can be implemented in phases with different elements being prioritized based on management information needs, condition of managed streams, and available resources. Monitoring for each element is based on one or more directed questions that guide specific monitoring designs:

Performance Assessment

- 1) How well do various BMPs, control strategies, and management measures perform relative to their design expectations and in light of how well they are maintained?
- 2) What factors influence the efficacy of hydromodification management strategies?

Effectiveness Assessment

- 3) How effective are specific management strategies at protecting the physical and biological integrity of streams from the effects of hydromodification (in the context of other watershed stressors)?
 - a) How do these effects compare to patterns at unimpacted “reference” sites?
 - b) Are the management strategies sufficiently protective of all stream types?
 - c) How does effectiveness vary by stream type (e.g. substrate, planform, slope)?

Spatial and Temporal Trends Assessment

- 4) What is the spatial footprint of response to hydromodification effects or management actions relative to discharge locations?
 - a) How far up or downstream do potential effects of hydromodification persist?

- 5) How do responses to hydromodification management vary over time?
 - a) What is the effect of natural rainfall and runoff patterns on stream response in the presence or absence of management measures?
 - b) How long do “restored” or “rehabilitated” stream reaches take to recover following remediation?
 - c) How do responses vary based on stream type (e.g. substrate, planform, slope) and environmental setting (e.g. watershed position relative to upstream land use, floodplain condition)?

Ambient (Characterization) Monitoring

- 6) What is the physical and biological condition of streams relative to established regulatory or management objectives?
 - a) How does condition vary by stream type (e.g. substrate, planform, slope) and environmental setting (e.g. watershed position relative to upstream land use, floodplain condition)?

In general, the first and second elements (performance and effectiveness monitoring) of hydromodification monitoring can be addressed by multi-year monitoring programs typically managed by municipalities and other local entities. In contrast, the third and fourth elements (trends and ambient condition) must be addressed over longer time scales (e.g., decadal) through cooperative regional monitoring that involves multiple entities including state, regional, local agencies and grant programs (Figure ES-1).

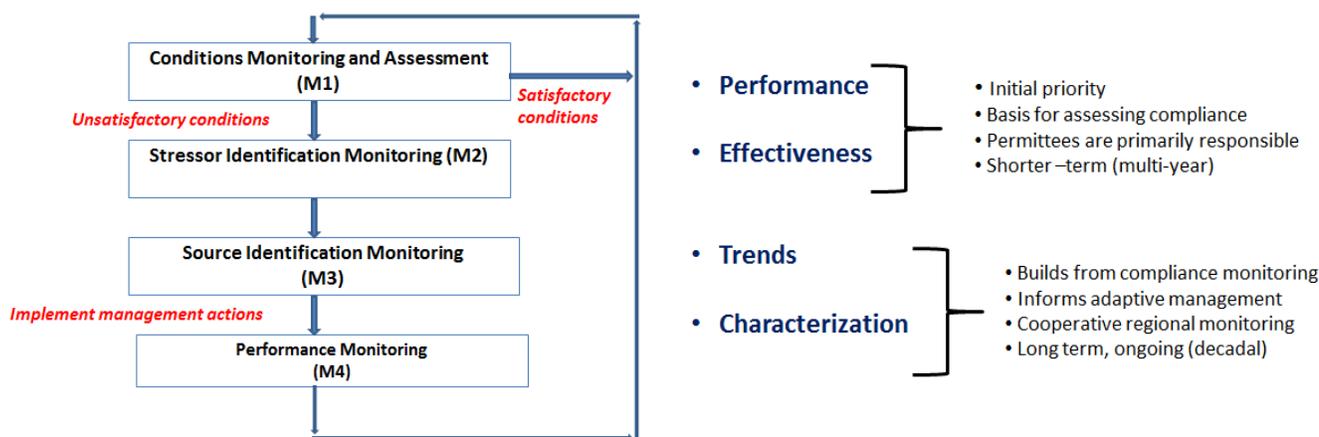

Figure ES-1. Major elements of hydromodification monitoring. General framework (left) and phasing (right)

Addressing all elements of the monitoring plan includes two basic designs: targeted and probabilistic sampling. Targeted sites include reference sites, sentinel sites, and sites downstream of specific BMPs or other management actions (e.g. restoration areas). A summary of the relationship between site types and monitoring questions is provided in Table ES-1.

Table ES-1. Relationship between type of monitoring site and management questions addressed.

Type of Site	Monitoring Questions
Reference sites	1. performance 3. effectiveness
Provide context	5. temporal trends 4. spatial extent of effects
Differentiate effects from natural variability	6. ambient condition
BMP monitoring sites	1. performance
Evaluate performance relative to goals	3. effectiveness (short term)
Evaluate compliance	
Targeted and sentinel sites	2. efficacy of management measures
Evaluate effectiveness of management actions	3. effectiveness 5. temporal trends
Evaluate spatial and temporal trends	4. spatial extent of effects 6. ambient condition
Probabilistic	3. effectiveness (short term)
Provide regional context	6. ambient condition
Interpret long-term trends	
Help understand natural variability	
GIS analysis	2. efficacy of management measures
Provide spatial context	
Provide insight into causal factors	

Three types of indicators are recommended for inclusion in hydromodification monitoring plans. Pressure indicators measure factors that can cause a response in the stream channel, such as flow. State indicators measure the physical condition of the stream and should include measures that can provide an early detection of potential channel response, such as shifts in the composition of the bed material or channel morphology. Response indicators measure the ecological endpoints of concern from a management perspective and should include long-term integrative measures of condition, such as benthic macroinvertebrates and algae. The pressure-state-response approach to monitoring includes measures of hydrology, geomorphology, and biology, as shown in Table ES-2.

Table ES-2. Summary of recommended field indicators along with their assessment endpoints and the monitoring questions that they support.

	Variable Type			Assessment Endpoint	Monitoring Questions
	P	S	R		
Hydrologic Indicators					
Stream flow	■	■		long term flow magnitude and duration	3, 4, 5
BMP inflow and outflow	■			discharge magnitude and duration	1, 5
Geomorphic Indicators					
Bed material composition		■		substrate size as d50	3, 4, 5, 6
Armoring potential		■		dominant substrate type and interstitial material	3, 4, 5, 6
Grade control		■		presences, spacing and condition of grade control	3, 4, 5, 6
Incision/downcutting risk		■		potential specific stream power relative to d50	3, 4, 5, 6
Probability of mass wasting		■		critical bank height and bank angle	3, 4, 5, 6
Evidence of fluvial erosion		■		evidence of erosion at the toe of slope	3, 4, 5, 6
Consolidation of bank material		■		field penetration tests of banks	3, 4, 5, 6
Channel width:valley width		■		active channel vs. floodplain	3, 4, 5, 6
Channel Evolution Model class		■		field observations of CEM class	3, 4, 5, 6
Channel geometry		■		channel cross-sections and longitudinal profile	1, 3, 4, 5
Physical Habitat Assessment (PHAB)	■	■		standard PHAB metrics	3, 4, 5, 6
Biologic Indicators					
Benthic macroinvertebrates			■	IBI, component metrics, functional groups	3, 4, 5, 6
Stream algae			■	IBI, component metrics, functional groups, biomass	3, 4, 5, 6
California Rapid Assessment Method	■	■	■	index score, attribute scores, metric scores	3, 4, 5, 6

Hydromodification monitoring should be a component of a larger integrated management program and should be prioritized in the context of other monitoring efforts (e.g. water quality, bio-objectives). Much of the baseline information necessary for the design of effective monitoring programs can be obtained by up-front watershed analysis. Watershed assessment also provides insight into the historic and contemporary causes of hydromodification, which can inform development of monitoring programs. The results of monitoring should be used to refine and adapt management programs over time.

Full benefits of monitoring accrue based on a commitment to long-term (multi-decadal) implementation, which requires infrastructure to support the monitoring program. We estimate the up-front per site cost to be \$5,250 and annual recurring per site cost to be \$11,500. If all monitoring elements were implemented, the annual cost would range from \$456,000 - \$569,500 per watershed management area, depending on the number of sites sampled each year. However, \$195,000 of that cost would be for ambient condition assessment at probabilistic sites. Monitoring elements can be phased and implemented by different entities in order to defray costs. Furthermore different elements of the monitoring plan can be prioritized based on condition of stream resources being protected and management priorities. The resources necessary to support long-term ongoing monitoring will be beyond the means of individual municipalities or permittees. Long-term implementation needs may be

most effectively met through coordination with existing monitoring programs and by sharing existing monitoring infrastructure. Over time, shared data can support causal assessment and provide information to improve hydromodification management.

This document can serve as a foundation to assist state agencies, local jurisdictions, and municipal stormwater permittees in developing detailed hydromodification monitoring plans to address their specific management and reporting needs. This document is intended to provide a set of monitoring elements that can be prioritized for implementation based on local needs; it is not intended to serve as prescriptive plan that should be universally implemented in all instances.

1.0 INTRODUCTION

Ongoing and well-structured monitoring is a critical component of watershed and water-quality management. Monitoring and management programs should be integrated such that practices intended to prevent or mitigate effects of land use on instream conditions should be refined and improved based on monitoring results. Monitoring is also important for assessing compliance with regulatory requirements and for evaluating program effectiveness. However, monitoring is only recently being applied to hydromodification management and with the exception of testing the efficacy of onsite BMP practices, standard approaches have not yet been developed.

Monitoring of hydromodification (i.e. alteration of runoff patterns associated with change in land use that result in change in physical channel conditions) management is particularly critical given the complexity and uncertainty associated with managing effects of hydrologic change on channel structure. Physical changes associated with changes in runoff are difficult to assess because they can result from a combination of contemporary land-use changes, legacy land practices (e.g. grazing), and stochastic events (e.g. floods and fires). Furthermore, channel adjustments can occur dramatically and rapidly after extended periods of apparent stability and can vary over small distances. Separating out the effects of human activity from natural cycles of channel evolution further complicates hydromodification monitoring and requires much longer term monitoring than traditional water quality programs. Due to the relative immaturity of hydromodification management practices as compared to traditional water-quality management, their effectiveness is also less certain. Thus, hydromodification monitoring is essential to allow adaptation and adjustment of early-generation practices to improve their performance over time.

Many stormwater permits require municipalities to develop “hydromodification monitoring plans” as part of their overall management programs. However, little guidance has been provided on the structure and content for these plans. As a result, monitoring plans vary in their approach and intensity. This inconsistency is inefficient, makes inter-jurisdictional comparisons and information sharing difficult, and precludes regional syntheses.

To begin addressing this issue, a statewide technical workgroup commissioned by the State Water Resources Board produced a broad set of recommendations for hydromodification monitoring as part of their report *Hydromodification Assessment and Management in California* (Stein et al. 2012). The proposed monitoring framework presented here is a tiered approach, designed to be executed at different spatial and temporal scales, to inform and help guide management actions.

In the context of hydromodification assessment and management, there are three interrelated purposes for monitoring which will guide the recommendations in this framework:

- Characterizing the conditions of receiving waters downstream of urban development (including any trends in those conditions over time).

- Evaluating the effectiveness of hydromodification controls at protecting or improving the conditions of downstream receiving waters *(and modify them, as needed).
- Setting priorities on the wide variety of hydromodification control practices.

These needs give rise to several interrelated types of monitoring, or elements, all common to many watershed and stormwater monitoring programs. They are typically executed at different spatial and temporal scales, and if well-designed and executed they can collectively help guide management actions. The four elements of the proposed monitoring framework include: 1) **performance monitoring** to evaluate whether a facility or practice meets its design objectives, 2) **effectiveness monitoring** to evaluate how well management actions or suites of actions reduce or eliminate the direct hydromodification impacts on receiving waters, 3) **trends monitoring** to provide an integrative assessment of whether our “endpoint” indicators (physical, chemical, or biological) are showing any consistent and statistically significant change over space and time, and 4) **ambient condition (characterization) monitoring** to provide context of the overall regional or watershed condition of receiving waters. In general, the first and second elements (performance and effectiveness monitoring) can be addressed by multi-year monitoring programs typically managed by municipalities and other local entities. In contrast, the third and fourth elements (trends and ambient condition) must be addressed over longer-time scales (e.g. decadal) through cooperative regional monitoring that must involve multiple entities include state, regional, and local agencies and programs (Figure 1). In practice, not all these elements need to be implemented at the same time or in the same locations. Implementation can be phased or tiered based on specific needs and resource constraints. Furthermore, different entities may be primarily responsible for different elements of the monitoring program (Table 1). In all cases, efforts should be coordinated between programs and entities to maximize the efficiency of implementation and opportunities for information sharing.

Figure 1. Major elements of hydromodification monitoring. General framework (left) and phasing (right)

Table 1. Phasing and different responsibilities for elements of hydromodification monitoring.

Timeframe	Programmatic: State and Regional Water Boards	Local: City and County Jurisdictions
Short-term (<10 years)	<ul style="list-style-type: none"> Define the watershed context for local monitoring (at coarse scale) Evaluate whether permit requirements are making positive improvements 	<ul style="list-style-type: none"> Evaluate whether specific projects/regulations are meeting objectives Identify the highest priority action(s) to take
Long-term (1+ decades)	<ul style="list-style-type: none"> Define watershed context and setting benchmarks for local-scale monitoring (i.e., greater precision, if/as needed) Demonstrate how permit requirements can improve receiving-water “health,” state-wide (and change those requirements, as needed) 	<ul style="list-style-type: none"> Evaluate and demonstrate whether actions (on-site, instream, and watershed scale) are improving receiving-water conditions Assess program cost-effectiveness Identify any critical areas for resource protection

The goal of this document is to build on the general recommendations provided by Stein et al. (2012) by providing more specific recommendations for hydromodification monitoring plans that address a set of common management questions in a consistent manner. This document can serve as a foundation to assist state agencies, local jurisdictions and municipal stormwater permittees in developing detailed hydromodification monitoring plans to address their specific management and reporting needs. This document is intended to provide set of monitoring elements that can be prioritized for implementation based on local needs; it is not intended to serve as prescriptive plan that should be universally implemented in all instances.

1.1 Hydromodification Monitoring in Context of Larger Management Programs

Hydromodification monitoring should be a component of a larger integrated management program (Figure 2). Watershed assessments conducted during development of integrated management programs provide much of the baseline information necessary for the design of effective monitoring programs. The location and intensity of monitoring (i.e. what gets monitoring at various locations) will depend on the stream types, opportunities and constraints identified during initial assessments. Similarly, the choice and location of management actions informs where monitoring should occur and what indicators are measured. Watershed assessment also provides insight into the historic and contemporary causes of hydromodification, which can inform development of monitoring programs. Therefore, monitoring programs should be developed using information compiled during these earlier efforts. The results of monitoring should be used to refine and adapt management programs over time.

It is also important to recognize that streams will respond to a variety of natural and anthropogenic stressors over varying time scales. Consequently, changes in condition detected as a result of a hydromodification monitoring program will need to be placed in the context of other stressors in the contributing drainage area (and their proximity to the stream reach being evaluated), climatic cycles, and recent disturbances (e.g. floods or fires). Management responses derived from hydromodification monitoring results should account for these factors and utilize other stream management programs as appropriate. Similarly, monitoring priorities should be established based on a consideration of the most important stressors acting on an individual watershed.

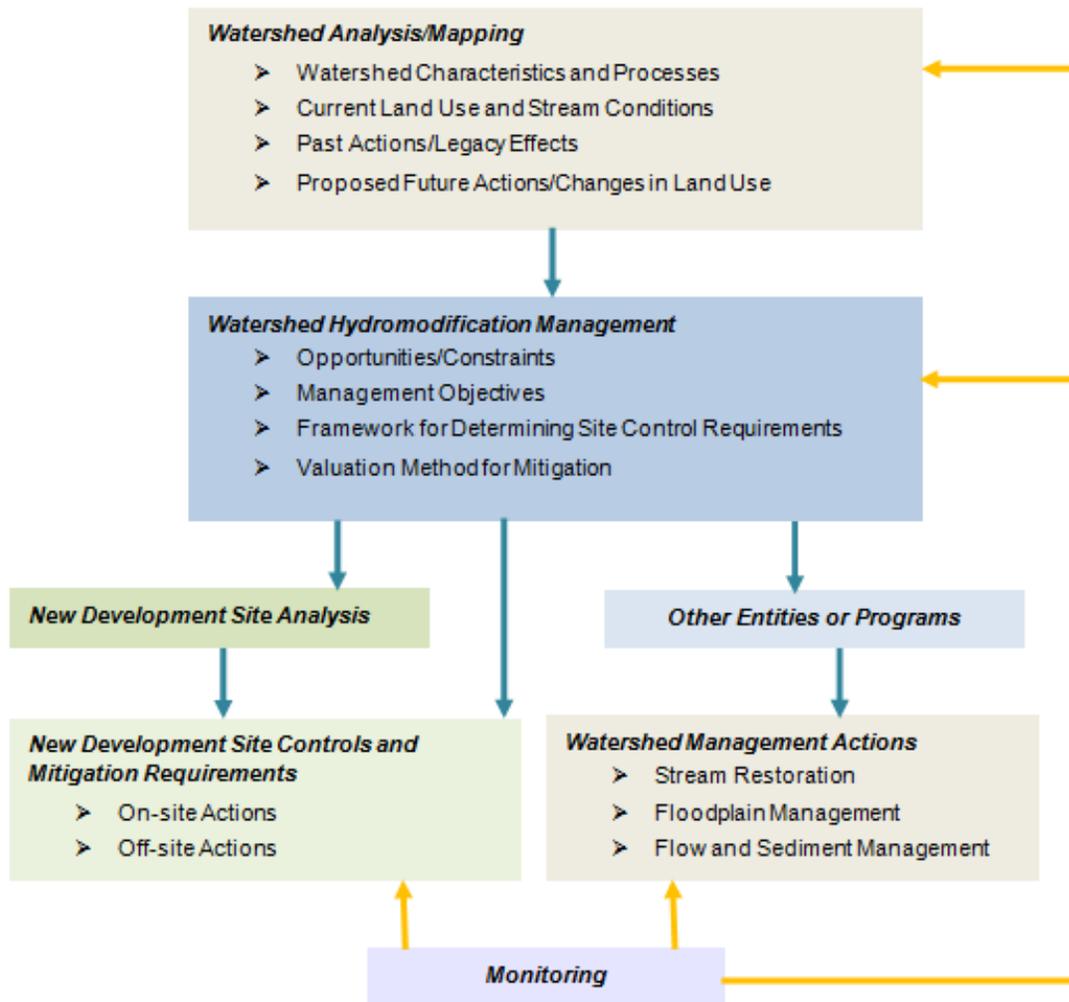

Figure 2. Framework for integrated hydromodification management.

1.2 Key Components of a Hydromodification Monitoring Plan

A successful monitoring plan will be flexible and adaptable, and will have a direct connection to management decisions. There are generally two priority management areas that drive the design of monitoring programs. The first is an evaluation of overall watershed and stream conditions, including stream health and beneficial uses. In its broadest sense, “health” encompasses chemical, physical, and biological integrity and should be evaluated using multiple indicators at multiple spatial scales (i.e., ranging from the entire landscape to site-specific). Hydromodification management is one of many important factors affecting watershed and stream health; therefore, hydromodification monitoring should be well integrated with regional programs that assess overall watershed and stream health. Causal assessment or stressor identification that may be conducted when conditions do not meet

agreed-upon goals and targets may identify hydromodification control as a priority action, increasing the importance of integrating hydromodification monitoring data into larger overall regional programs. The first priority management area should be addressed at a cooperative programmatic scale, involving multiple entities at state, regional, and local agencies and programs.

The second priority area is an assessment of compliance with regulatory requirements. This may include monitoring performance of specific BMPs or management measures and evaluation of whether targets, objectives, and beneficial uses have been met in receiving waters. Permittee-directed hydromodification monitoring will typically focus on this second priority area. However, as stated above, because regulatory compliance may be obtained by achieving overall watershed health, compliance and watershed condition monitoring must be coordinated at every level and by all responsible parties.

To address the two priority management areas discussed above, a Hydromodification Monitoring Plan should include the following attributes:

Plan is question-driven and has clear assessment endpoints. All components of design and data collection should support the core management questions.

Plan is multidimensional. Different factors should be designed to answer the various core questions (e.g. receiving water monitoring, BMP monitoring).

Multiple indicators are used. Using multiple hydrologic, physical, and biological indicators to assess effects of management actions provides a more robust assessment and increases the ability to diagnose potential stress-response relationships. In some cases the primary stressors may be something other than hydromodification. It is important to note that some indicators may only apply in certain types of streams (e.g. benthic invertebrates in wadeable streams).

Plan is modular. A modular design allows elements to be implemented in a phased or incremental manner and to build on existing programs. Different aspects can be implemented based on interest and management information needs. It may not be necessary (or desirable) in some cases to implement all elements of the monitoring program concurrently. A modular design also allows the level of effort to be adjusted commensurate with factors such as the value of resources at risk, the level and certainty of effects, monitoring priorities, and the availability of funding. It also allows for iterative refinement of the overall program based on early monitoring results.

Plan is consistent with other regional programs. Common monitoring protocols allow for consistent application from project to project and across different programs. Data consistency will also allow information to be compiled across programs to build larger, more robust, long-term monitoring data sets that can be readily compared. A consistent regional approach will require development of common quality control procedures and information management/data transfer protocols.

Plan is adaptive. Monitoring data should be directly tied back to the core questions in order to assess the effectiveness of management actions. Monitoring results should be used to inform changes in the selection and implementation of management strategies, to support regional watershed models, and to adapt future monitoring priorities. This will require coordination between the various entities implementing hydromodification monitoring. Adaptive feedback is particularly important for hydromodification because management techniques are relatively new and approaches are expected to evolve over time based on early implementation experience (Figure 3).

Figure 3. Adaptive feedback relationship between monitoring and other elements of hydromodification management.

1.3 Primary Monitoring Questions

The specific monitoring design is guided by monitoring for each of the four elements discussed above. When developing a tiered approach to hydromodification monitoring it is advisable to analyze the highest priority element(s) and focus resources in that area. Six primary monitoring questions are recommended in order to adequately address all elements of the monitoring framework keeping in mind that every Hydromodification Monitoring Plan should be designed to meet local needs. The following management questions should be considered in the plan development process.

1.3.1 Questions Answered through Local-Agency Led Monitoring over Shorter Timeframes Performance Assessment

- 1) How well do various BMPs, control strategies and management measures perform relative to their design expectations and in light of how well they are maintained?
- 2) What factors influence the efficacy of hydromodification management strategies?

Effectiveness Assessment

- 3) How effective are specific management strategies at protecting the physical and biological integrity of streams from the effects of hydromodification (in the context of other watershed stressors)?
 - a. How do these effects compare to patterns at unimpacted “reference¹” sites?
 - b. Are the management strategies sufficiently protective of all stream types?
 - c. How does effectiveness vary by stream type (e.g. substrate, planform, slope)?

1.3.2 Questions answered through regional/programmatic monitoring over longer timeframes Spatial and Temporal Trends Assessment

- 4) What is the spatial footprint of response to hydromodification effects or management actions relative to discharge locations?
 - a. How far up or downstream do potential effects of hydromodification persist?
- 5) How do responses to hydromodification management vary over time?
 - a. What is the effect of natural rainfall and runoff patterns on stream response in the presence or absence of management measures?
 - b. How long do “restored” or “rehabilitated” stream reaches take to recover following remediation?
 - c. How do responses vary based on stream type (e.g. substrate, planform, slope) and environmental setting (e.g. watershed position relative to upstream land use, floodplain condition)?

Ambient (Characterization) Monitoring

- 6) What is the physical and biological condition of streams relative to established regulatory or management objectives?
 - a. How does condition vary by stream type (e.g. substrate, planform, slope) and environmental setting (e.g. watershed position relative to upstream land use, floodplain condition)?

Questions #1 to #3 should be the focus of a local agency/permittee-directed hydromodification monitoring program, but can benefit by regional cooperation with other entities. Questions #4 to #6 should be addressed through coordination of hydromodification monitoring with a watershed or regional monitoring program involving multiple entities at the state, regional and local levels. The latter questions can only be answered through long-term sustained monitoring. This is particularly true since hydromodification effects may only occur under specific circumstances (e.g. storms of certain size or duration). Long-term (multi-decadal) data sets will be necessary to separate effects of management actions (or lack thereof) from natural variability in channel conditions. It should be noted that the approach to answering these questions can also apply to the objectives of other monitoring programs

¹ Reference is currently defined as “minimally affected by human activities” in the Reference Condition Management Program (Ode et al. 2009). Where possible, regional reference sites can be used.

under NPDES permits, watershed plans, or regional monitoring programs. Integration of hydromodification monitoring with other monitoring efforts should be a priority, with the ultimate goal being an integrated watershed-scale monitoring and assessment program. Such a program would allow for sharing of reference sites, sampling sites and information across programs and jurisdictions in order to allow leveraging of effort/information and more coordinated management responses. This involves mapping the location and type of various monitoring efforts and developing mechanisms for data sharing. Monitoring implementation should include time to develop and sustain the necessary inter-departmental and/or inter-agency coordination associated with the integrated monitoring approach.

It is important to note that hydromodification has the potential to affect all water body types; therefore, hydromodification management and the associated monitoring should address potential effects to all streams and receiving waters. Because streams are most directly affected by hydromodification, they have been the focus of current regulatory requirements and, therefore, most management programs. Consequently, this document emphasizes tools and approaches applicable to fluvial systems, which are broadly defined to include wadeable streams, large rivers, headwater streams, intermittent and ephemeral drainages, and alluvial fans (although new specific tools may be necessary for assessment and management of alluvial fans). We recognize, however, that hydromodification can also affect nearshore and coastal environments, including bays, harbors, and estuaries, by altering estuary channel structure, water quality, sand delivery, siltation, and salinity. These effects have been less extensively studied or documented and have received substantially less attention in current hydromodification requirements. Future efforts should more directly address hydromodification effects to all receiving waters, but the information is not presently available to provide equally comprehensive guidance here.

1.4. Adaptive Monitoring through Hypothesis Testing

As with all monitoring programs, this plan should be adaptive. Early monitoring results should be used to refine questions and the associated monitoring design over time. For a plan to be truly adaptive the core questions must be predicated on a set of testable hypothesis. Not every hypothesis can be fully tested at all times; however; they provide a consistent framework for the development of adaptive monitoring designs.

1.4.1 Hypotheses that Drive the Monitoring Plan

Performance Assessment

BMPs will perform as designed over a range of storm conditions and will be maintained adequately to perform effectively.

Effectiveness Assessment

Specific management strategies can help protect the physical and biological integrity of streams from the effects of further hydromodification.

Flow duration control is better than no control or peak flow control at reducing impacts, but effectiveness will be influenced by site conditions.

Management practices that contribute to dynamic channel stability, also contribute to healthy biotic communities.

The effectiveness of flow duration control based BMPs at preventing excessive erosion/channel instability will vary based on the degree of change in sediment supply.

Spatial and Temporal Trends Assessment

Hydromodification management will promote dynamic stability of channels and natural fluctuations in cross-section and planform that are similar to streams from minimally impacted areas.

Hydromodification management will protect against upstream or downstream propagation of channel erosion or deposition.

Ambient Condition (Characterization) Monitoring

Hydromodification management measures will allow streams to meet objectives established under watershed plans or regulatory requirements.

Stream or receiving water type, bed-material, slope (landform), and geologic setting, as well as past, present, and future land use determine overall watershed processes and influence the degree to which hydromodification effects may be manifested.

2.0 GENERAL MONITORING APPROACH

Answering the core questions requires different design approaches, several suites of indicators, and varying time scales, frequencies and durations. The basic monitoring elements are summarized in Table 2 and discussed in detail in the following sections. *As noted above, the overall monitoring program can be implemented in a modular or phased manner and does not need to be implemented all at once.* Specific questions can be addressed as they become relevant or as preliminary data suggests that more intensive monitoring would be beneficial. Also as noted above, the permittee-directed monitoring should focus on performance effectiveness assessment. Permittees should cooperate with integrated regional monitoring programs to answer spatial and temporal trends and overall characterization questions. It is important to note that separating the effect of hydromodification management over time from natural patterns of channel evolution will require long-term (multi-decadal) monitoring, which is often beyond the timeframe typically associated with traditional water quality monitoring programs.

Design of a monitoring program (as well as decisions regarding management actions) can benefit from watershed analysis that summarizes the general condition of various areas, and identifies opportunities and constraints. Watershed analysis should begin with a documentation of watershed characteristics and processes, and past, current, and expected future land uses. The current condition of streams and their response trajectories should be examined in the context of past alterations to streamflow, sediment delivery, and direct manipulations of physical habitat such as channel straightening and armoring. The analysis should lead to identification of existing opportunities and constraints that can be used to help prioritize areas of greater concern, areas of restoration potential, infrastructure constraints, and pathways for potential cumulative effects. The combination of watershed and site-based analyses should be used to establish clear objectives to guide monitoring and management actions. These objectives should articulate desired and reasonable physical and biological conditions for various reaches or portions of the watershed and should prioritize areas for protection, restoration, or management. Strategies to achieve these objectives should be customized based on consideration of current and expected future channel and watershed conditions. For example, stream restoration is probably not a viable option if substantial changes in upstream water and sediment delivery are anticipated in the future. A one-size-fits-all approach should be avoided. Even where site-based control measures, such as flow-control basins, are judged appropriate, their location and design standards should be determined in the context of the watershed analysis. Maps and landscape-scale data produced as part of the watershed analysis should inform the hypothesis and management questions upon which monitoring programs are based. Similarly, interpretation of monitoring data should rely on insights and understanding provided by watershed analysis. Watershed analysis provides a critical foundation for monitoring programs, but is often neglected due to time or resource constraints. Efforts should to include this important step will provide long-term benefits in terms of program design and interpretation of results.

Table 2. Summary of recommended monitoring design elements.

Monitoring Question	Design	Location criteria	Season	Frequency	Duration	Sampling triggers	Indicators
Performance Assessment							
1) How well do various controls strategies and management measures perform relative to their design expectations	targeted	location of regional or site-specific BMPs + undeveloped reference sites	storm season	annually for first 5 years after installation	periodically after first 5 years based on performance	enhance monitoring following large storms or substantial changes in land use	inflow and outflow rates from BMPs over storm duration, flow and x-secs immediately d/s of BMPs + comparable reference site data
2) What factors influence the efficacy of hydromodification management strategies?	map/GIS based + review of targeted data	watershed wide GIS + evaluation of data from specific settings	N/A	once at the start of monitoring program and then updated periodically based on changes in land use/infrastructure		substantial changes in land use, infrastructure or other watershed attributes	GIS, supported by field based stressor identification
Effectiveness Assessment							
3) How effective are specific management strategies at protecting the physical and biological integrity of streams from the effects of hydromodification?	Targeted w/BACI design	upstream and downstream of selected BMPs, multiple locations	dry season and continuous flow measures	annually for first 5 years	after yr 5, integrate with regional monitoring	enhance monitoring following large storms or substantial changes in land use	screening tool measures, physical habitat assessment, bioassessment, channel cross-sections, flow
Spatial and Temporal Trends Assessment							
4) What is the spatial footprint of hydromodification responses relative to discharge locations?	targeted	upstream and downstream of selected BMPs, multiple locations	dry season	every 2-3 years	ongoing	increase frequency following large storms & substantial change in land use	screening tool measures, physical habitat assessment, bioassessment, channel cross-sections
5) How do responses to hydromodification management vary over time?	targeted	sentinal or integrator sites + reference sites	dry season and continuous flow measures	every 2-3 years	ongoing	none	screening tool measures, physical habitat assessment, bioassessment, channel cross-sections, flow
Characterization Monitoring							
6) What is the physical and biological condition of streams relative to established regulatory or management objectives?	probabalistic + sentinal sites	stratified by stream type or management unit + reference and integrator sites	dry season	annually in a rotating design	ongoing	possible intensification following stochastic events such as floods or fires	screening tool measures, physical habitat assessment, bioassessment
<i>screening tool measures</i> = cross sections, bed material composition, floodplain width, bank height & angle, grade control, Channel Evolution Model (CEM) class							
<i>bioassessment</i> = benthic macroinvertebrates, algae, California Rapid Assessment Method (CRAM)							
<i>GIS</i> = land use, structures, channel types, Channnel Evolution Model (CEM) classes if available							
<i>BACI</i> = Before-after-control-impact							

2.1 Monitoring Design and Site Selection/Location Considerations

The overall monitoring plan includes two basic designs: targeted and probabilistic sampling. Targeted sites include reference sites, sentinel sites, and sites downstream of specific BMPs or other management actions (e.g. restoration areas). A summary of the relationship between site types and monitoring questions is provided in Table 3.

Targeted sites should be selected in order to best evaluate the specific management questions.

Targeted sites include those used to evaluate effects of management actions and those that serve as watershed reference sites. In addition, the following general criteria should be considered:

- Appropriate scale: the upstream area should be dominated by, or at least significantly affected by, the management action of interest.
- Responsiveness: at the chosen location, the indicators being measured should be amenable and relatively sensitive to change in response to the management action.
- Representativeness: the results at the chosen location should be credibly extrapolated to “similar” sites, and those sites in aggregate should constitute a widespread (or otherwise important) subset of the landscape as a whole.
- Access: the site should be easily and safely reached by the appropriate personnel and equipment, and with a cost of doing so consistent with the frequency of measurements being made. Any equipment left unattended needs to be secure from theft or vandalism, or must be well-hidden.

Probabilistic sites should be selected at random using methods developed by the USEPA and the Stormwater Monitoring Coalition (SMC; Stevens et al. 1997, USEPA 2002, SCCWRP 2007). Randomly selected sites can be stratified into groups based on physical setting, management priorities, or specific assessment questions. An existing “master sample draw” has been developed in southern California as part of the SMC’s regional watershed monitoring program. This existing draw can be used to provide an unbiased set of site locations to support the ambient characterization monitoring under Question #1. This will also facilitate coordination of hydromodification monitoring with existing regional and NPDES required monitoring.

Routine review of aerial and ground-based photography can also be a powerful and relatively inexpensive tool to help select probabilistic sites and support monitoring programs. Aerial photography can be used to identify areas of the watershed analysis that require updating due to changed conditions. Aerial photographs can be used to evaluate floodplain width, planform changes, channel migration, and floodplain obstructions or constrictions (either natural or anthropogenic). This information can provide a screening level evaluation of condition that can be used to prioritize locations for more specific ground-based monitoring. Aerial photographs are also important for reconnaissance of candidate sites for ambient condition assessment (Question #6). They can also provide a general overview of the

condition of the site over time (e.g. before and after construction of a BMP), can help refine specific field sampling locations, and are a relatively easy way to support assessments of potential causes of effects (Question #2), spatial extent of effects (Question #4) and trends (Question #5).

Efforts should be made to coordinate the locations of both probabilistic and targeted hydromodification monitoring sites with sites being used for other monitoring programs. This may or may not be possible given the specific needs of different programs in terms of site types, flow conditions, locations etc. However, where possible sharing sites between programs can increase efficiency and reduce costs. In addition, Questions #1, #5, and #6 involve comparison to relatively unimpacted reference sites as a means of increasing the power to detect effects (Loftis et al. 2001). Selection of these sites can be based on the existing Reference Condition Management Program (Ode et al. 2009) and informed by the watershed analysis described above.

Table 3. Relationship between monitoring questions and types of sites used to answer each question. Shading indicates that the specific site type is used to answer the indicated monitoring question.

		Monitoring Question					
		Performance		Effectiveness	Spatial		Characterization
		1	2	3	4	5	6
Type of Site		How well do various controls strategies and management measures perform relative to their design expectations	What factors influence the efficacy of hydromodification management strategies?	How effective are specific management strategies at protecting the physical and biological integrity of streams from the effects of hydromodification?	What is the spatial footprint of hydromodification responses relative to discharge locations?	How do responses to hydromodification management vary over time?	What is the physical and biological condition of streams relative to established regulatory or management objectives?
Reference sites		developed sites with no BMPs					
Provide context							
Differentiate effects from natural variability							
BMP monitoring sites							
Evaluate performance relative to goals			short term				
Evaluate compliance							
Targeted and sentinel sites							
Evaluate effectiveness of management actions			short and long term				
Evaluate spatial and temporal trends							
Probabilistic							
Provide regional context			Long-term				
Interpret long-term trends							
Help understand natural variability							
GIS analysis							
provide spatial context							
provide insight into causal factors							

2.2 Monitoring Season, Duration, and Frequency

Most monitoring questions can be answered via data collected during the non-storm (dry season). The exception is the evaluation of BMP performance and other measures of stormflow or sediment transport, which will typically occur during the storm flow conditions. Questions #1 to #3 can initially be evaluated over the five-year timeframe associated with a typical permit cycle; however, in many cases several permit cycles may be necessary to fully address these questions. The time necessary to answer these questions may be longer based on several factors that are often out of the control of permittees. For example, BMP performance and stream response may require rainfall patterns necessary to trigger specific size flow events, which may only occur periodically. Second, the pace of development and redevelopment may influence when BMPs or other management measures are constructed and can then be monitored.

Questions 4-6 will need to be evaluated over longer time periods (i.e. multiple decades) as part of a regional monitoring program; often relatively long monitoring periods (>10 - 15 years) are required to detect change (Loftis et al. 2001). A subset of sites used to address Questions #1 to #3 may be rolled into long-term regional monitoring programs. *Finally, the value of long-term flow data should not be underestimated, particularly for evaluating the effects of hydromodification management. Establishing flow monitoring stations at key locations should be a high priority for hydromodification monitoring programs.*

2.3 Monitoring Indicators

Field indicators need to meet several objectives. First, the monitoring program should include indicators of pressure, state and response (Figure 4). Pressure indicators measure factors that can cause a response in the stream channel, such as flow. Stream flow is the first link in the causal chain between management practices and stream response. State indicators measure the physical condition of the stream and should include measures that are able to provide an early detection of potential channel response, such as shifts in the composition of the bed material or channel morphology. Physical habitat is determined by interactions between flow and channel structure; therefore, it is necessary to monitor state indicators of the geomorphic characteristics that mediate the effects of hydromodification on biological endpoints. Response indicators measure the ecological endpoints of concern from a management perspective, and should include long-term integrative measures of condition, such as benthic macroinvertebrates and algae. The pressure-state-response approach to monitoring means that the monitoring program will include measures of hydrology, geomorphology, and biology, as described below.

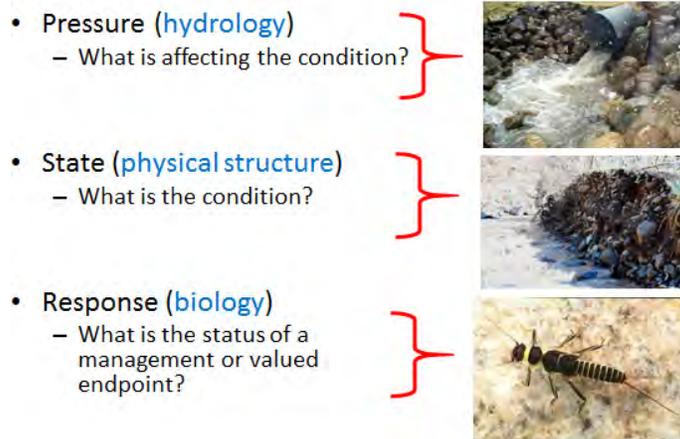

Figure 4. Pressure-state-response approach to monitoring.

In a general sense, response variables measure the overall “health” of a stream and are used to make decisions as to whether intervention is necessary to improve overall condition. State variables provide insight into the physical conditions that affect biological response variables. Together, state and response variables can be used to help prioritize where management action is necessary and how intensive that management action should be. Pressure variables provide insight into “what needs to be changed” to improve stream condition, and (together with state variables) can be used to guide specific management responses (e.g. altering flow conditions).

It is important to note that many stream channels of concern that are impacted by hydromodification will be ephemeral or intermittent, particularly in Southern California. Some commonly used bioassessment indicators (e.g. benthic macroinvertebrates) may not be usable in extremely dry streams (such as those without persistent baseflow through the spring). In such cases, other indicators such as those included in the California Rapid Assessment Method (CRAM; CWMW 2012) will apply. In addition, monitoring entities may want to include general habitat assessments, including several metrics contained in the California Physical Habitat Protocol (Ode 2007) to evaluate biological condition of streams. As new bioassessment indicators for intermittent and ephemeral streams are developed, they can be added into existing programs.

Stressors other than hydromodification (e.g. pollutant discharges, invasive species infestations) may contribute to changes in stream condition. Consequently, many of the indicators used may be responding to multiple factors. This should be accounted for during analysis and interpretation of monitoring data and should be used to identify opportunities for cooperation with other monitoring and management programs.

The selected indicators should be practical from a cost and logistics perspective, have an established scientific basis, have direct ties to designated uses, have existing protocols available, and provide information that can serve broader monitoring objectives beyond hydromodification assessments. In

many cases, the recommended indicators may already be included in existing monitoring programs. Recommended field indicators are summarized in Table 4 and discussed in detail below.

Table 4. Summary of recommended field indicators along with their assessment endpoints and the monitoring questions that they support.

	Variable Type			Assessment Endpoint	Monitoring Questions
	P	S	R		
Hydrologic Indicators					
Stream flow				long term flow magnitude and duration	3, 4, 5
BMP inflow and outflow				discharge magnitude and duration	1, 5
Geomorphic Indicators					
Bed material composition				substrate size as d50	3, 4, 5, 6
Armoring potential				dominant substrate type and interstitial material	3, 4, 5, 6
Grade control				presences, spacing and condition of grade control	3, 4, 5, 6
Incision/downcutting risk				potential specific stream power relative to d50	3, 4, 5, 6
Probability of mass wasting				critical bank height and bank angle	3, 4, 5, 6
Evidence of fluvial erosion				evidence of erosion at the toe of slope	3, 4, 5, 6
Consolidation of bank material				field penetration tests of banks	3, 4, 5, 6
Channel width:valley width				active channel vs. floodplain	3, 4, 5, 6
Channel Evolution Model class				field observations of CEM class	3, 4, 5, 6
Channel geometry				channel cross-sections and longitudinal profile	1, 3, 4, 5
Physical Habitat Assessment (PHAB)				standard PHAB metrics	3, 4, 5, 6
Biologic Indicators					
Benthic macroinvertebrates				IBI, component metrics, functional groups	3, 4, 5, 6
Stream algae				IBI, component metrics, functional groups, biomass	3, 4, 5, 6
California Rapid Assessment Method				index score, attribute scores, metric scores	3, 4, 5, 6
<i>P: pressure variable</i> <i>S: state variable</i> <i>R: response variable</i>					

2.3.1 Hydrologic Indicators

Stream Flow

Stream flow can be a pressure variable in that it affects physical and biological condition of the channel. It can also be a state variable to the extent that it describes the environment in which biota live and directly respond. Continuous flow monitoring is an important element of effectiveness monitoring. In addition, the magnitude and duration of erosive flow events at targeted locations should be measured during storm events; monitoring should commence prior to increase in flow in response to stormwater runoff and continue through peak flow until discharge falls below a threshold of significant sediment transport. Flow should be measured at a portion of the channel with a well-defined cross-section, with relatively uniform flow, and that does not experience hydraulic backwater effects, that can be used to rate flow (i.e. relate water surface elevation to discharge). These constraints should be considered when selecting monitoring locations in channels with multiple or distributed flow paths. Technical guidance on open channel flow measurement methods is available from the USGS, USDA Bureau of

Reclamation, USEPA and numerous State water-quality monitoring program websites. A summary of guidance on measuring streamflow is provided in Appendix A.

BMP Inflow and Outflow

Outflow characteristics from site-specific or regional BMPs are pressure variables. Inflow and outflow should be monitored following representative storms and compared to the design standards of the BMP or basin. A subset of representative BMPs or other facilities could be subject to ongoing monitoring beyond the initial performance assessment period. Consideration must be given to monitoring requirements during BMP design/site permitting/BMP construction, in order to accommodate continuous outflow measurements. Technical guidance on pipe flow measurement methods is available from the USGS, USDA Bureau of Reclamation, USEPA and numerous State water-quality monitoring program websites.

As a pressure variable, stream flow and BMP outflow are factors that can be directly affected by management measures. Therefore, they can be used as proximate measures of the effect of those management measures and as compliance points.

2.3.2 Geomorphic Indicators

Screening Tool Indicators

The Hydromodification Screening Tool developed by SCCWRP and Colorado State University (Bledsoe et al. 2010, 2012) provides a set of relatively simple to measure, but quantitative, field indicators designed to provide a rapid assessment of the relative susceptibility of a specific stream reach to effects of hydromodification. These same field indicators should be used as state variables to assess general condition of a stream reach relative to hydromodification effects. The screening tool includes the following field indicators, with more detail available in Bledsoe et al. 2010:

- Bed material composition, expressed as d_{50}
- Armoring potential measured as combination of dominant substrate type and interstitial material
- Presence and condition of grade control
- Incision/downcutting risk based on the potential specific stream power relative to d_{50}
- Probability of mass wasting based on critical bank height and angle
- Evidence of fluvial erosion at the toe of bank
- Consolidation of bank material
- Width of the active channel relative to the overall valley width
- Channel condition relative to the state of the Channel Evolution Model (Hawley et al. 2012)

Channel Geometry

Channel cross-sectional area and longitudinal profile is a state variable and often serves as an assessment endpoint for determining hydromodification response or recovery. Geomorphic surveys of channel cross-sections should be guided by the field protocol of Harrelson et al. (1994) and performed

by a knowledgeable/experienced survey crew using a total station and data collector or level/rod. Surveys should occur over 10 bankfull channel widths. Surveys should include at least three cross-sectional profiles (upper, mid, lower reach) that extend to either the valley edge or above the apparent 25 year floodplain. Channel surveys and photo points looking upstream and downstream should be tied to “permanent” control points or monuments tied to a geodetic framework (such as NAD 27 or 83).

Physical Habitat Assessment (PHAB)

PHAB data can serve as a pressure or state variable. The PHAB protocol (Ode 2007) is part of the standard bioassessment procedures already conducted as part of many compliance and ambient monitoring programs. PHAB measures a series of physical channel characteristics, riparian, substrate, and human alterations along 11 transects over a 150 to 200 m stream reach. These data are converted to “metrics” used to evaluate the general condition of physical habitat and the suitability of the stream to provide habitat for benthic macroinvertebrates. These same metrics provide insight into stability or response of the stream channel to hydromodification effects.

State variables are monitored for several reasons: 1) they provide a measure of the physical condition of channels relative to hydromodification and thus can be used as measures of compliance or effectiveness of management measures; 2) they indicate areas that require management attention and therefore help guide and prioritize management measures; and 3) they help link pressure variables, such as flow, with response variables, such as biology and therefore help provide mechanistic insight how stream ecosystems respond to hydromodification and hydromodification management.

2.3.2 Biologic Indicators

Benthic Macroinvertebrates

Benthic macroinvertebrate community composition and indices of biological integrity (IBIs) are response variables that can be used to assess overall health of instream communities. As with PHAB, benthic macroinvertebrate assessments are routinely conducted as part of many existing ambient assessment and compliance monitoring programs. Benthic macroinvertebrates shall be collected using the multi-habitat method described in the SWAMP protocol (Ode 2007). Identifications will be done according to the Standard Taxonomic Effort Level 2 for California benthic macroinvertebrates, as described in Richards and Rogers (2007). Benthic macroinvertebrate assessments can be done in perennial wadeable streams and non-perennial streams with persistent baseflow through the spring sampling index period. Other biological indicators such as fish or plants will need to be developed and/or used in streams with deep water flow and in ephemeral streams.

Stream Algae

Bioassessment tools based on instream algae are another response variable often used in concert with benthic macroinvertebrates to assess overall instream health relative to known stressors. Algal bioassessment includes measures of soft-bodied algae, cyanobacteria, and diatoms. Assessments are typically conducted in two ways; biomass and taxonomic identification. Algae are collected using the multi-habitat method described in the SWAMP protocol (Fetscher et al. 2009). As with the benthic

invertebrates, algal assessment can be done in perennial wadeable streams and non-perennial streams with persistent baseflow through spring sampling index period.

[California Rapid Assessment Method \(CRAM\)](#)

CRAM assessments include pressure, state and response variables. CRAM is a standardized assessment method that typically can be completed by a two-person crew in less than four hours in the field per site. It evaluates general conditions relative to four attributes (landscape context, hydrology, physical structure, biological structure) based on a set of structured field observations and includes an evaluation of stressors that may affect condition. CRAM applies to perennial and non-perennial streams and assessments are conducted during the spring-summer plant growing season. Protocols for CRAM assessments are provided in the CRAM user's manual version 6.0 (CWMW, 2012) and on the CRAM website at www.cramwetlands.org.

Response variables measure the biological health of streams, which is the ultimate desired management endpoint. A primary goal of water quality programs is to protect and restore instream biology, so measuring it directly is a direct measure of success. Furthermore, regulatory programs, such as freshwater bio-objectives, increasingly use biological endpoints as compliance measures.

2.3.4 GIS Indicators

GIS indicators should be developed as part of the watershed analysis described above and should include factors that both control and affect watershed processes. Key GIS indicators will include:

- Topography and valley slopes based on the digital elevation models
- Surficial geology from USGS or the California Geologic Survey
- Soil types and infiltration/drainage/runoff characteristics from NRCS or local data
- Land use/land cover from the National Land Cover Database or higher resolution local data
- Existing channel conditions and mapped channel structures
- Channel widths relative to floodplain widths (including floodplain restrictions and obstructions)
- Existing flood control facilities and water quality or flood control basins
- Locations of BMPs, restoration projects and other management actions
- Footprint of regional fires (updated annually)
- Areas of particular environmental, economic, social, or management concern

3.0 SPECIFIC MONITORING APPROACHES

Each of the six monitoring questions (listed in Section 1.3) includes specific design considerations such as specific site selection criteria, frequency and duration of sampling, triggers to initiate monitoring events, and priority indicators. These elements are discussed for each question in the subsections below. As noted above, the elements should be viewed as modules that can be implemented in various combinations and at various timeframes based on need and resource constraints. It is not necessary (nor may it be desirable) to implement all elements at the onset of a monitoring program. Phased implementation allows for adaptation and prioritization. Hydromodification monitoring should be coordinated with other monitoring efforts where there is overlap (e.g. other stormwater programs, water quality certifications under Section 401 of the Clean Water Act, ambient stream monitoring).

Performance Assessment (Local Agency/Permittee Directed)

3.1 Question #1

How well do various controls strategies and hydromodification management measures perform relative to their design expectations?

This is the main question used to evaluate the performance of representative BMPs or other hydromodification management measures. Effectiveness is evaluated by measuring inflow and outflow characteristics from management areas (e.g. floodplain restoration sites, basins)² or BMPs, relative to design parameters. Where possible, continuous flow monitoring should be conducted for the first several years following BMP installation and as an ongoing measure for large or regional BMPs. Understanding the performance of management measures is an important component of regulatory compliance. Results from this question should be used to adapt and improve management practices over time in order to inform future decisions about the design and placement of BMPs. Performance of management measures is a core element of adaptive management that will increase the ability to protect and restore stream channels into the future.

3.1.1 Design and Location Criteria

BMP performance is best achieved through targeted sites located at the outflow of BMPs or other management measures. . In some instances, BMP performance assessment may be pooled regionally instead of conducted within each Watershed Management Area. Data from these sites is used to evaluate their performance relative to design criteria and in the receiving channel downstream of the BMP. Post construction/implementation, representative BMPs should be monitored to determine if they are performing as intended and/or if modifications are necessary to achieve desired performance. Over the long-term a subset of the representative sites could be monitored to aid in evaluation of trends and long-term performance patterns over a variety of climatic and site conditions. Sites should be selected to represent the categories or types of facilities required and/or constructed based on permit

² Management measures may include BMPs or other facilities, locations of floodplain or stream restoration, or alternative land use practices designed to mitigate the effects of hydromodification.

requirements and watershed plans. These categories should include both site-based and regional facilities and those with different design goals (e.g. flow-duration control, retention/infiltration, capture/use, sediment management).

3.1.2 Sampling Season, Frequency, and Duration

Performance monitoring should occur during the storm season because most hydromodification BMPs are designed to help manage stormwater runoff. It is preferable to have continuous flow monitoring occur throughout the storm season for several years following installation in order to provide robust information on representative BMP performance. If this is not possible, at least three storms should be monitored per season. Continuous flow measurements should be initiated at the start of each monitored storm event and continue until all retained water has been discharged from the facility or infiltrated. A subset of representative BMPs and reference sites should be monitored annually to assess performance relative to design specifications.

3.1.3 Specific Sampling Triggers

Monitoring should be initiated based on two triggers. First, each new facility that is not already included in the set of representative BMPs should be monitored. The immediate downstream areas should also be monitored (for representative BMPs). Second, monitoring intensity should be increased following major storm events that may influence BMP performance. If the preferred continuous flow monitoring approach is used, it will provide information over a range of conditions representing seasonal and episodic variability, eliminating the need to increase monitoring intensity following large storms.

3.2 Question #2

What factors influence the efficacy of hydromodification management strategies?

Improved management over time comes from an understanding of the factors that affect the effectiveness of various management actions. Information gained from other monitoring can only be interpreted through such an understanding. Therefore, such “causal evaluation” is an integral part of a comprehensive monitoring program. Evaluation of factors that affect performance is best done through a GIS-based landscape assessment, supported by targeted field evaluation of potential stressors (or pressure indicators). In practice, the outcome of Questions #2 and #3 should be used together to support causal assessment that informs management decisions. This assessment should use much of the same information compiled as part of the watershed analysis that forms the foundation of the overall monitoring program. GIS indicators should be supplemented by field documentation of stressors observed during monitoring activities associated with the other management questions. In particular the CRAM stressor checklist, PHAB, and flow data can provide field-derived insight into the causes of decline or recovery of a particular stream reach.

3.2.1 Design and Location Criteria

Causal assessment is not monitoring in the true sense, but occurs through targeted assessment of potential causes of failure or factors that contribute to success. This evaluation should occur at the watershed scale and consider all upstream and downstream contributing factors. The watershed analysis that forms the foundation of the integrated monitoring program can form the basis of this assessment. In addition, causal evaluation frameworks such as the USEPA Causal Analysis/Diagnosis Decision Information System (CADDIS, <http://www.epa.gov/caddis/index.html>) can be used to evaluate past data sets and provide insight into causes of management measure effectiveness. Results of the watershed-scale analysis may suggest targeted locations for more detailed investigations where field based measures can be used to support the causal evaluation.

3.2.2 Sampling Season, Frequency, and Duration

Because this question is answered mainly through GIS analysis it can occur in ongoing and as-needed manner. As results are obtained from the other monitoring questions, this analysis should be updated and revised to improve understanding of causes of success and failure.

3.2.3 Specific Sampling Triggers

As with other questions, the analysis of causation should be intensified following substantial changes in land use practices or following installation of new management measures. Unlike other questions, natural catastrophic events such as fires and floods would not necessarily trigger intensified causal assessment. Additional field assessment should be triggered if performance monitoring under Question #1 reveals that individual (or groups) of BMPs are not functioning as intended.

Effectiveness Assessment (Local Agency/Permittee Directed)

3.3 Question #3

How effective are specific management strategies at protecting the physical and biological integrity of streams from the effects of hydromodification?

The efficacy of management measures is a function of BMP performance (Question #1) and the effect of those management actions on instream conditions (Question #3). A combination of physical and biological measures taken at channel cross-sections downstream of the BMPs can be used to evaluate effectiveness (Table 5). These measures can be evaluated against comparable assessment conducted prior to the BMP being installed and to unimpacted reference locations³. Results from this question should be used to adapt and improve management practices over time in order to inform future

³ In some watersheds, it may be difficult to find unimpacted reference sites. In this situation regional reference sites may be used (hence the importance of maintaining reference networks). Pre-project data is especially important when reference sites are difficult to locate.

decisions about the design and placement of BMPs. This is a core element of adaptive management and will hopefully increase ability to protect and restore stream channels into the future.

Table 5. Field indicators for measuring effectiveness of hydromodification management.

Geomorphic Indicators	Biologic Indicators
Bed material composition	Benthic macroinvertebrates
Armoring potential	Stream algae
Grade control	California Rapid Assessment Method
Incision/downcutting risk	
Probability of mass wasting	
Evidence of fluvial erosion	
Consolidation of bank material	
Channel width:valley width	
Channel Evolution Model class	
Channel geometry	
Physical Habitat Assessment (PHAB)	

In addition, as stated above, long-term continuous flow data will be valuable in assessment of BMP effectiveness.

3.3.1 Design and Location Criteria

A before-after-control-impact (BACI) design (Stewart-Oaten et al. 1986) is recommended for assessing hydromodification management effectiveness. Targeted stream reaches downstream of BMP locations should be sampled prior to and after BMP installation/construction (at least 2 seasons of pre-BMP sampling are recommended). The condition of the stream channel receiving the BMP discharge should be considered when deciding where to monitor effectiveness. For example, BMPs that discharge into engineered channels or streams subject to a variety of other stressors may not be appropriate for effectiveness monitoring. Instead, effectiveness monitoring should be prioritized in areas where BMPs discharge to soft-bottom channels where the influence of other stressors is relatively minimal.

If possible, a set of reference sites should also be selected that receive runoff from relatively natural landscapes. The paired design increases statistical power to detect differences associated with management actions from natural variability associated with seasonal and decadal scale climate patterns. Because different channel types will respond differently, different channel susceptibility classes should be included for reference sites and streams downstream of BMPs (i.e. high, medium, low according the screening tool developed by Bledsoe et al. 2010). If possible to obtain, three replicate reference sites should be included for each major channel category. Reference sites are also an important component of trends monitoring (see Question #5). Therefore, to the extent possible, these sites should have ownership and access conducive to long-term ongoing monitoring.

3.3.2 *Sampling Season, Frequency, and Duration*

Instream conditions can be evaluated during the dry season when appropriate to sample biological indicators. Channel cross-sections should be taken at least annually for the first five years following BMP installation/construction (frequency may increase following catastrophic events, see below). If possible, continuous flow monitoring stations should be installed in order to accurately capture hydrograph shapes even in small, flashy basins. Following the initial monitoring period a subset of representative sites (and reference sites) should be monitored annually as part of long-term (decadal) regional monitoring programs. Long term monitoring is important as there may be a substantial lag time between land use changes and/or initial management actions and stream responses.

3.3.3 *Specific Sampling Triggers*

Monitoring should be initiated based on two triggers. First, construction of each new representative BMP should initiate monitoring of that BMP (Question #1) and the immediate downstream area (in addition, to the recommended pre-construction monitoring) – for a representative set of sites. Second, monitoring intensity should be increased following major storm events or fires. Following these events, sites should be monitored more frequently within a storm season (i.e. number of storms per year should increase) for the first three years following the catastrophic event. The need for continuing high intensity monitoring beyond this time period should be evaluated based on the results from the first three years.

Spatial and Temporal Trends Assessment (Cooperative Statewide or Regional Monitoring)

Questions #4 and #5 can only be answered through long-term coordinated monitoring that crosses jurisdictional boundaries. Therefore, these questions should be addressed through cooperative programs at the state or regional level (e.g. southern California) that is coordinated by appropriate state or regional agencies. It is recommended that a pilot project focusing on Questions #4 and #5 be conducted first prior to implementation on a larger scale

3.4 Question #4

What is the spatial footprint of hydromodification responses relative to discharge locations?

Hydromodification effects have the potential to propagate upstream or downstream from a discharge location. Therefore, assessing the success of management measures requires an evaluation of the spatial extent of effects. This is best accomplished through a long-term regional monitoring program. Spatial effects are monitored during the dry season at a series of targeted location along a stream corridor. Measures include channel cross-sections and the same physical and biological indicators used to evaluate effectiveness (Question #3, see Table 3). In some cases the same sites may be used to answer spatial extent and effectiveness questions. Results from this question should be used in combination with the results of trends monitoring (Question #5) and compared to the causal factors

evaluated under Question #2. These comparisons will allow a more robust analysis of the effect of management actions.

3.4.1 Design and Location Criteria

Question #4 is best addressed through targeted sampling. Spatial effects should be evaluated upstream and downstream of the same set of management areas or BMPs monitored for Question #1, if suitable areas exist⁴. Monitoring sites should be channels with unarmored bed and banks that would be subject to potential effects of hydromodification. In general, the “analysis domain” should be consistent with and extend slightly downstream of the limits suggested by the Hydromodification Screening Tool (Bledsoe et al. 2010). In brief, the analysis domain proposed by Bledsoe et al. (2010) for downstream monitoring should occur to the first location that meets one of the following criteria:

- at least one reach downstream of the first grade-control point (but preferably the second downstream grade-control location)
- tidal backwater/lentic waterbody
- equal order tributary (Strahler 1952)
- a 2-fold increase in drainage area

Upstream monitoring should extend for a distance equal to 20 channel widths OR to grade control in good condition – whichever comes first. Within that reach, identify hard points that could check headward migration, evidence that head cutting is active or could propagate unchecked upstream. As with Question #3, different channel types are expected to respond differently. Therefore, ideally 3-5 sites representing high, medium, and low susceptibility (per Bledsoe et al. 2010) should be monitoring for each category of management action. Priority should be given to high and medium susceptibility sites, if resources pose a constraint. Sites should be conducive to long-term monitoring in terms of logistics and access.

3.4.2 Sampling Season, Frequency, and Duration

Sampling consists of the same physical and biological indicators measured for Question #3. Therefore, sampling should occur during the spring sampling season during the index period for benthic invertebrate and algal sampling protocols (typically April – June depending on weather conditions). Because sites used to answer this question are intended to be monitored over extended periods of time, sampling every other year is typically sufficient (subject to the triggers described below). Furthermore, as described below the downstream extent may need to change over time based on monitoring results. Many monitoring programs re-evaluate the general monitoring design at a regular interval, typically every five years, and make adjustments to accommodate evolving management needs.

⁴ It may also be desirable to select several legacy BMPs from other parts of the watershed to include in this element of the monitoring program.

3.4.3 *Specific Sampling Triggers*

Monitoring should be initiated based on the same triggers used for Question #3. First, construction or installation of a new representative BMP should initiate monitoring of that BMP (Question #1) and the immediate downstream area (Question #3). State and local agencies should coordinate to identify representative BMPs for monitoring. Second, monitoring intensity should be increased following major storm events or fires. Following these events, sites should be monitored more frequently for the first three years following the major event. The need for continuing high intensity monitoring beyond this time period should be evaluated based on the results from the first three years.

Spatial extent monitoring should also include an adaptive element. If effects are consistently observed downstream of BMPs or other management measures over several years, the monitoring location should be extended further downstream. This will allow incremental improvement in the ability to determine the actual extent of potential downstream effects. Note that this should include consideration of how past influences (e.g., headcutting from historical, pre-urban impacts) may interact with contemporary influences

3.5 **Question #5**

How do responses to hydromodification management vary over time?

Trend monitoring is particularly important for understanding hydromodification effects given that stream channel response is often stochastic/episodic and may occur suddenly following certain size storms or under specific combinations of circumstances. Conversely, gradual effects may persist for decades and stabilization and recovery following restoration and management may be manifested over long periods of time. Monitoring sentinel sites over long periods of time is the best way to understand these long-term effects and trajectories and to develop data sets with sufficient statistical power to detect change. Most of the monitoring should occur during the dry season and should include channel cross-sections the same physical and biological indicators used to evaluate effectiveness (Question #3, see Table 3). In addition, continuous flow monitoring through wet and dry seasons at key locations is necessary to understand effect of management measure over time. Trends monitoring is best accomplished through a long-term regional monitoring program. In some cases the same sites may be used to answer trends and effectiveness questions.

3.5.1 *Design and Location Criteria*

Trend monitoring should occur at two types of targeted sites. First, sentinel sites should be established at key watershed locations in consideration of past and current land use practices. These may also include locations downstream of important long-term management areas, such as regional retention basins or large floodplain restoration projects. They may also be at locations that integrate portions of the larger watershed (e.g. major tributary confluences). When choosing sites near confluences, care should be taken to not establish the monitoring site at the confluence, but just upstream of the confluence. This will reduce potential confounding factors associated with dynamism that often occurs

when two different size catchments join. Second, reference sites should be monitored to help document a baseline range of variability in response to normal decadal scale weather patterns. These natural adjustments will help bound the range of expected responses at sites subject to management measures. As with Questions #3 and #5, different channel types are expected to respond differently. Therefore, ideally 3-5 sites representing high, medium, and low susceptibility (per Bledsoe et al. 2010) should be represented in both the sentinel and reference sites. Priority should be given to high and medium susceptibility sites if funding poses a constraint. All trend sites should be amenable to long-term monitoring in terms of access and logistics.

3.5.2 *Sampling Season, Frequency, and Duration*

Trend monitoring should occur during both the wet and dry seasons. Dry season sampling consists of the same physical and biological indicators measured for Question #3. Therefore, sampling should occur during the spring sampling season during the index period for benthic invertebrate and algal sampling protocols (typically April – June depending on weather conditions)⁵. Wet season sampling consists of continuous flow monitoring and channel cross-section analysis. If continuous flow monitoring is not possible, event-based flow monitoring should occur during one of the three storm events monitored for Question #1, preferably an early season storm of moderate intensity. Discharge measurements should be initiated at the start of each monitored storm event and continue until flow has receded to at least 50% of peak flow. Continuous flow monitoring at 15-minute intervals is preferred, if possible. Channel cross-section and longitudinal profile should be surveyed immediately following the end of each monitored storm event. Ideally, sampling would occur at least every other year on an ongoing basis. Many monitoring programs re-evaluate the general monitoring design at a regular interval, typically every five years, and make adjustments to accommodate evolving management needs.

3.5.3 *Specific Sampling Triggers*

Trend monitoring should occur annually at the targeted reference and effects sites. If natural or anthropogenic factors cause a trend site to no longer be suitable for monitoring, it should be replaced with a comparable site. Monitoring intensity should be increased following major storm events or fires. Following these events, sites should be monitored more frequently for the first three years following the catastrophic event. The need for continuing high intensity monitoring beyond this time period should be evaluated based on the results from the first three years.

Ambient Condition Monitoring (Cooperative Statewide or Regional Monitoring)

3.6 Question #6

What is the physical and biological condition of streams relative to established regulatory or management objectives?

⁵ Many suitable sites for hydromodification monitoring will be dry for most of the year. These sites may be not be amenable to benthic macroinvertebrate or algae sampling.

This question provides an estimate of the regional extent and range of hydromodification effects through an ambient assessment of physical and biological conditions within the stream. This information provides context for interpreting the results of all other monitoring questions. Results from ambient condition monitoring document the range of expected conditions and provide insight into how those conditions vary across physical gradients such as slope, geologic setting, and watershed position. Monitoring should occur during the dry seasons and should include channel cross-sections and the same physical and biological indicators used to evaluate effectiveness and trends (Questions #3 to #5, see Table 3). Where possible, long-term continuous flow monitoring should also be used to help answer this question. Results from targeted monitoring from subsequent questions can be compared to the ranges produced by this question.

3.6.1 Design and Location Criteria

The characterization question is best answered through a probabilistic design. Probabilistic design allows for statistical inference of overall condition in the monitoring area based on sampling at a relatively small set of randomly selected locations. Sites can be stratified by watershed or other management unit of interest or can be sampled as a single stratum and then grouped later for comparative analysis. As a general rule, approximately 30 sites should be sampled per stratum to provide a statistically meaningful estimate of overall condition within the monitoring area. In southern California, the Stormwater Monitoring Coalition (SMC) has a regional monitoring program covering the region from Ventura through San Diego counties that has produced a set of randomly selected sites. The SMC sites could also serve as locations for assessing the regional extent of hydromodification effects.

3.6.2 Sampling Season, Frequency, and Duration

Ambient condition assessment should occur during the spring sampling season during the index period for benthic invertebrate and algal sampling protocols (typically April – June depending on weather conditions). Sampling should occur annually on an ongoing basis. Many monitoring programs re-evaluate the general monitoring design at a regular interval, typically every five years, and make adjustments to accommodate evolving management needs. The current SMC regional monitoring design involves sampling a different set of probabilistic sites each season. This design typically provides the most robust assessment of regional condition. However, revisiting a portion of previously sampled sites can provide information to support trends assessment (see Question #5).

3.6.3 Specific Sampling Triggers

Ambient monitoring typically involves sampling a specific number of sites each year irrespective of environmental conditions. However, intensified sampling may be desirable if substantial changes to the condition of a specific area are expected in association with a natural event (e.g. large flood or fire) or land use change (e.g. large new development area, major stormwater basin). Under these circumstances additional probabilistic sites can be selected from the regional sample draw and monitoring for a discrete period of time. This will help determine if there is a change in ambient condition in the specific area of interest.

3.7 Summary of Monitoring Locations

A hypothetical layout for all elements of this monitoring plan is shown in Figure 5 (note that the number of sites shown are for illustrative purposes only and not meant to imply an actual program). As stated above, this plan can be implemented modularly based on needs and not all elements would need to be implemented together (i.e. use as a toolbox of approaches). The first two elements (performance and effectiveness monitoring) will typically be implemented by permittees as part of their monitoring requirements. The second two elements (trends and characterization monitoring) are best done through long-term cooperative regional monitoring. However, all monitoring elements should be closely coordinated, particularly because individual sites may serve multiple roles (e.g. a site used for trends assessment may also be a reference site or an upstream BMP site). Also, a subset of sites initially used for permittee-directed monitoring may ultimately be incorporated into regional monitoring programs. Where possible, sites (or data) from other monitoring programs may be used to also support hydromodification monitoring.

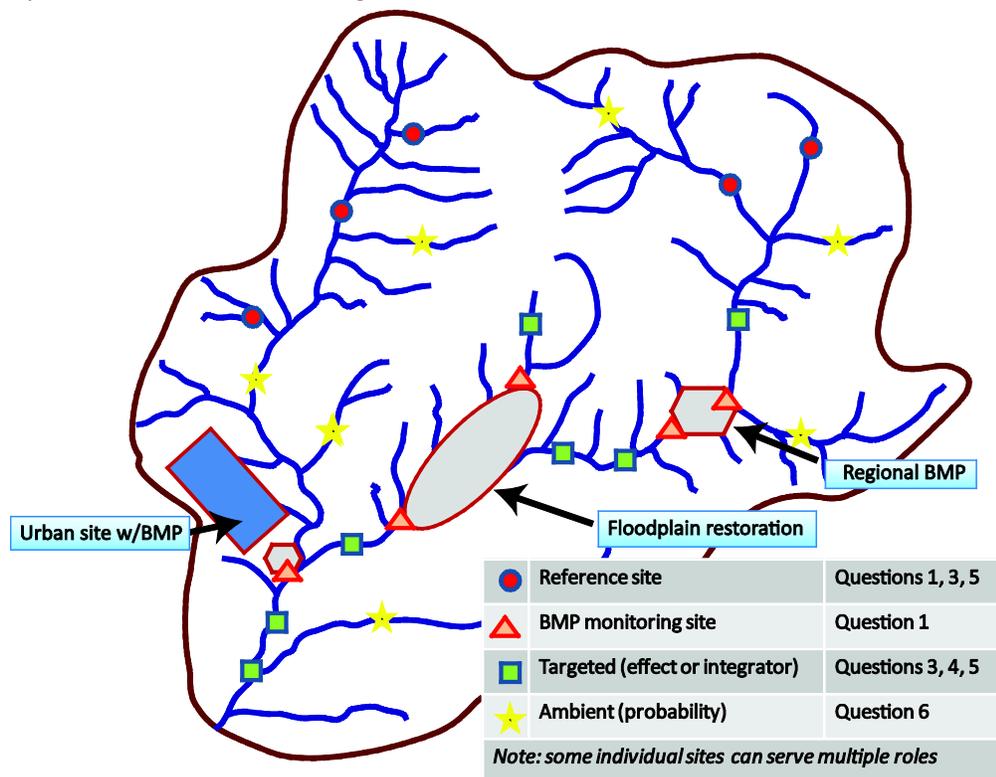

Figure 5. Hypothetical summary of how monitoring site might appear in a watershed. The number and locations of sites is for illustrative purposes only and are not meant to represent an actual program.

3.8 Preliminary Cost Estimates

Implementation of the recommended monitoring elements will require both up-front commitment of resources and recurring annual expenditures. Table 6 provides estimated unit costs per site for the major recommended field indicators.

Table 6. Unit costs for one-time up front and recurring annual monitoring of major indicators.

One time, up front costs		Recurring Annual Costs	
Flow		Flow	
pressure transducers	\$1,250	annual data download/processing	\$5,000
station set up	\$1,000		
Total	\$2,250	Biology and Geomorphology	
Biology and Geomorphology		Field geomorphic assessment	\$2,000
site recon & selection	\$2,000	field collection of inverts and algae	\$2,000
access and permits	\$1,000	CRAM	\$1,000
Total	\$3,000	benthic inverts taxonomy	\$600
		diatoms taxonomy	\$400
		data entry, QA/QC	\$500
		Total	\$6,500

We estimate the up-front per site cost to be \$5,250 and annual recurring per site cost to be \$11,500. Based on general recommendations in this chapter we also provide a range of estimates for annual monitoring costs for each type of monitoring site and each major indicator (Table 7). If all monitoring elements were implemented, the annual cost would range from \$456,000 - \$569,500 per watershed management area, depending on the number of sites sampled each year. However, \$195,000 of that cost would be for ambient condition assessment at probabilistic sites. The overall costs do not include monitoring infrastructure, such as data management, training, and reporting. As stated above, the intent is not for all elements to be implemented concurrently or by the same entity. Rather, we anticipate that various elements would be implemented over time by a combination of local and regional partners in order to defray costs and make implantation more practical. The costs provided in Table 7 should be considered preliminary estimates only.

Table 7. Preliminary cost estimates for each type of site and indicator representing the major monitoring elements.

Type of Site	Monitoring Questions	No. of sites	Flow		Biology and Geomorphology	
			up-front one-time	recurring annual cost	site recon: up-front, one time cost	recurring annual cost
BMP monitoring sites	1	6 - 9	\$13,500 - \$20,250	\$30,000 - \$45,000		
BMP reference sites (sites w/o BMPs)	1	3 - 5	\$6,750 - \$11,250	\$15,000 - \$25,000		
Instream effectiveness monitoring sites	3	6 - 9			\$18,000 - \$27,000	\$39,000 - \$58,500
Spatial effects sites	4	12 - 15			existing locations	\$78,000 - \$97,500
Trends sites	5	6 - 9	\$13,500 - \$20,250	\$30,000 - \$45,000	use existing effectiveness sites	
Reference sites	3, 4, 5, 6	6 - 9	\$13,500 - \$20,250	\$30,000 - \$45,000	\$18,000 - \$27,000	\$39,000 - \$58,500
Probalisitic sites	6	30			\$90,000	\$195,000

4.0 USE OF MONITORING RESULTS TO SUPPORT DECISIONS

Monitoring should not be a static endeavor. In addition to answering the core monitoring questions, information compiled through the monitoring programs should be used to inform management decisions and to guide evolution of the monitoring program itself. Results of the monitoring program should be added to the original watershed analysis and used to support issues such as:

- Identifying successful management measures that should be replicated in other areas and unsuccessful measures that should be modified or abandoned.
- Identifying areas of the watershed in need of additional management attention
- Conducting statistical power analysis to refine the location and frequency of monitoring and to improve protocols
- Providing data to refine, calibrate, and validate watershed models
- Improving understanding of the stress-response relationships between flow, physical habitat, and biological communities in order to support the evaluation of potential causes of degradation.

Full benefits of monitoring accrue based on a commitment to long-term implementation, which requires decision support systems and infrastructure to support the monitoring program. The resources necessary to support long-term ongoing monitoring will be beyond the means of individual municipalities or permittees. A long-term commitment to hydromodification monitoring can be best accomplished through a long-term regional grant program. Long-term implementation needs can be most effectively met through coordination with existing monitoring programs and by sharing existing monitoring infrastructure.

4.1 Triggers for Management Actions

Monitoring results should not only assess performance/compliance, but should inform adaptive management decisions. Hydromodification management is an immature field relative to other forms of water quality management. Consequently, there are relatively high levels of uncertainty associated with long-term effects of management actions.

Triggers for specific management actions will need to be developed for each watershed program consistent with the goals, objectives, and regulatory requirements of that program. These triggers can be informed by many factors, such as:

- Established regulatory limits (e.g. deviation from an objective, change in bioassessment score)
- Differences from reference conditions
- Deviations from pre-project conditions
- Deviations from a specified percentile of ambient conditions

Management actions may be informed by results of effectiveness or condition monitoring. Results of the effectiveness monitoring (Question #3) can trigger changes in the design of facilities or restoration areas (i.e. retrofits) or changes in operation (e.g. frequency of basin clean outs, elevation or size of discharge outlets). For example, a magnitude or duration of outflow from a basin of more than 15% greater than the designed specification could trigger specified management actions. Results from condition monitoring (Questions #4 and #5) can also trigger actions, such as additional causal assessment or implementation of contingency management measures (e.g. additional floodplain restoration). For example, an increase in channel cross sectional area of 15% greater than reference conditions could trigger the need for additional upstream restoration. Similarly, IBI scores consistently below a specific level could trigger the need to initiate a formal causal assessment. However, it is important to note that several watershed stressors may be contributing to the response observed during monitoring. The combined effects of hydromodification along with other stressors should be accounted for during the causal assessment.

Along with adaptation of management actions, monitoring results should also inform evolution of the monitoring program itself. Such “adaptive management” requires long-term commitment to the program; consequently, cooperation with ongoing regional monitoring programs become more critical. As the hypothesis underlying the monitoring program are supported or refuted, the design, location, frequency and/or choice of indicators should be adjusted. Results of early monitoring should inform refinements of subsequent years monitoring. For example, information on how far downstream hydromodification effects propagate (Question #4) can result in changes to the spatial extent of monitoring. Information on the rate of channel evolution (Question #5) can result in a change in the frequency of monitoring or adjustment of the triggers for intensified monitoring. Finally, increased knowledge on the sensitivity of specific indicators at detecting changes may result in some indicators being dropped and new indicators being added, or change in the overall intensity of monitoring.

4.2 Data Management, Information Dissemination, and Reporting

Realization of the goals of any monitoring program to inform management actions depends on an effect data management program. This is particularly important for watershed based monitoring program where information will need to be shared across jurisdictions. Monitoring programs should take advantage of regional data management systems, such as the California Environmental Data Exchange Network (CEDEN; <http://www.ceden.org>) and its associated Regional Data Centers. This requires up-front development of standard data formats that can be shared across programs. The Regional Data Centers provide secure web-based portals through which data can be accessed in a variety of ways. The goal is to provide an easy mechanism for retrieving monitoring results so that they can be used to inform management decisions.

Regular reporting should be directly related to the monitoring questions. Synthesis and analysis should be designed to clearly answer the questions and hypothesis in a way that informs decisions. If management triggers have been developed, data summaries should directly relate to whether triggers have been surpassed. Furthermore, monitoring results should be made readily available to decision

makers and the public as a means of education and to show the outcomes of the investment of resources toward addressing hydromodification.

4.3 Quality Assurance

Confidence in monitoring data requires standardized procedures for sample collection, processing, analysis, and data reporting. These procedures must be established up-front and clearly communicated through the various data and information management systems (see above). Quality assurance procedures are necessary for managers to have confidence in the quality of the data used to support their decisions. Data Quality Objectives (DQOs) are quantitative and qualitative statements that clarify study objectives, and specify the tolerable levels of potential errors in the data. DQOs are generally used to determine the level of error considered to be acceptable in the data produced by the monitoring program.

Ongoing training and field audits of monitoring sites should also be included as part of the quality assurance program. These actions will help ensure consistency and accuracy in data collection, which will be essential to the ability to synthesize data over time and space.

4.4 Final Considerations

This monitoring program includes aspects that are different than what is typically included in existing water quality monitoring. Monitoring methods, approach and program management will require developing new skills and capacities at the local and regional level. In addition, logistical challenges such as identifying sufficient, appropriate monitoring sites, securing site access, data management, and training of field staff will need to be addressed. We recommend that several pilot demonstration projects be conducted in order to provide an opportunity to refine the recommendations provided in this document and develop examples of program implementation. These early efforts will provide important lessons and templates that can be used to aid in long-term broad implementation. From the regulatory perspective, new frameworks may need to be developed to accommodate adaptive management and to encourage and facilitate integrated, watershed and regional scale solutions to hydromodification monitoring and assessment.

APPENDIX A: BIBLIOGRAPHY OF SOURCE INFORMATION ON STREAMFLOW MEASUREMENT

Flow measurement is a key component of hydromodification monitoring. Long-term continuous flow monitoring provides much more robust data for general evaluation, assessment of management measure effectiveness and model calibration or validation. Although, less desirable, regular manual measurements of flow also provide important data for understanding behavior and response of stream channels.

There are many different approaches to measuring streamflow ranging from direct measures of velocity and cross-sectional area to relatively inexpensive approaches that measures stage (i.e. height of the water surface) and translate that to discharge using an established relationship based on channel geometry. The accuracy of the measurement is affected by the specific approach, the complexity of the technique and practitioner performance. The references below provide background information on various approaches, limitations and considerations for use, and description of protocols.

Rantz, S.E., et al. (1982). *Measurement and Computation of Streamflow: Volume 1. Measurement of Stage and Discharge*. United States Geological Survey Water-Supply Paper 2175. Washington D.C.

This report is a training and operations manual for USGS technicians that describes gaging station installation, and measurement of stage and discharge. It provides guidance on selecting a site for a gaging station, including considerations of channel geomorphology that come into play. Fundamentals of stage measurement are discussed and various methods used in recording and non-recording stream gaging stations are described. The report also discusses the fundamentals and theory of several methods of stream discharge measurement techniques, provides a practical description of the procedures and equipment used, and describes technical issues associated with each. There is also a discussion of the indirect determination of peak discharge.

Rantz, S.E., et al. (1982) *Measurement and Computation of Streamflow: Volume 2. Computation of Discharge*. United States Geological Survey Water-Supply Paper 2175. Washington D.C.

This report is a training and operations manual for USGS engineers to process field measurements into relationships of stage and discharge, to compute daily-discharge records, and to create a graphical representation of the stage and discharge relationship. It covers in detail the computation of stage-storage relationships for various gaging station equipment configurations and provides detailed procedural guidance for documenting, reporting, presenting and publishing gaging station records and computed stage-discharge relationships.

Various downstream natural hydraulic controls and various man-made controls of known geometry are discussed with respect to their effects on stage and discharge relationships. The report covers in depth the topic of determining, analyzing, and correcting for various causes of shift in the stage-storage relationship due to changes in various man-made and natural stream controls, and due to ice effects. It also discusses some typical causes of shift seen in the stage-discharge relationship in sand-channel streams relative to fixed channels, and methods for troubleshooting and properly charting and adjusting

the rating curve. Methods for extrapolation of stage-discharge relationships beyond measured data both on the low and high ends of the flow spectrum are reviewed.

The report contains a discussion of the theory and provides several methods for determining discharge ratings for tidal streams and other instances of variable backwater, or discharge--such as at hydraulic facilities--which may require extra parameters such as slope and velocity index. Additionally, it presents examples for establishing the relationships, with further discussion of the theory and methods for adjusting unsteady flow rating curves to represent steady flow conditions.

Freeman, Lawrence A. et al. (2004). *Use of Submersible Pressure Transducers in Water-Resources Investigations*. United States Geological Survey Techniques of Water-Resources Investigations 08-A3: Reston, VA.

Pressure transducers are commonly used to measure water surface elevation in stream gaging. This report presents the theory behind data collection using pressure transducers, particularly in well-type installations. The report describes the fundamentals of data collection protocol, and provides guidance on various field methods for installation, data processing (refining and calibrating), and quality assurance of collected data. There is a discussion of the physics and electronic circuitry behind pressure transducer operation, as well as the errors inherent in the system. Examples of application in various environments are discussed, along with typical related operational difficulties and potential solutions.

Mueller, David S. and Wagner, Chad R. (2009). *Measuring Discharge with Acoustic Doppler Current Profilers from a Moving Boat*. United States Geological Survey Techniques and Methods 03-A22. Reston, VA.

This report explains in detail the procedures for measuring discharge using an Acoustic Doppler Current Profiler (ADCP). It provides procedures for equipment preparation, field methods and equipment configurations for data collection, and data management and processing, including quality control. The report discusses the theory behind ADCP measurement technology, including potential limitations. It relates this discussion to practical use, providing procedures for equipment calibrations and maintenance adjustments to address various performance issues.

**MODELING AND MANAGING HYDROMODIFICATION EFFECTS:
SUMMARY OF AVAILABLE TOOLS
AND DECISION-MAKING APPROACH**

Eric D. Stein and Brian P. Bledsoe

Technical Report 753

March 2013

EXECUTIVE SUMMARY

Hydromodification management has traditionally focused on addressing excessive erosion or deposition in channels and the resulting geomorphic changes. The evolution of stormwater management beyond a focus on water chemistry is an important step forward in holistic efforts to protect the physical, chemical, and biological integrity of water courses. However, current approaches to hydromodification have been limited to managing runoff at the site of new or re-development. Although this approach is beneficial, there is a need for hydromodification management to evolve to a watershed-based approach focused on restoration and protection of watershed processes. Accomplishing this requires developing and organizing new tools and approaches that support integrative assessment and management. This document summarizes suites of modeling tools that can be used to help characterize and predict the complex and multifaceted effects of hydromodification. We also present an approach for developing management prescriptions that account for the specific needs and constraints of individual stream reaches in the context of the watershed in which they exist.

Modeling tools can be organized into four basic categories in increasing level of complexity: descriptive tools, statistical models, mechanistic models with deterministic outputs, and probabilistic models. Descriptive tools are the easiest to apply, but typically provide only general or coarse resolution output. Statistical and mechanistic models are more precise, yet require more data input for their use. Finally, probabilistic models are relatively new for stream analysis, but have the advantage of providing an explicit account of model uncertainty. In most cases, multiple modeling tools will be necessary to fully assess potential hydromodification effects; however, the precise combination of tools applied will vary based on needs, quality of streams being managed, and available resources.

We have developed several new tools, which are also described in this document. These include:

- Revised regional hydrologic curves for estimating discharge in ungauged basins.
- Analytical regime diagrams that allow prediction of changes in channel dimensions based on changes in water or sediment discharge.
- A regional update to the channel evolution model that illustrates expected trajectories of channel response to hydromodification.
- Several statistical channel enlargement models based on regression using local data.
- An artificial neural network model for predicting change in channel cross-sectional area based on a suite of watershed variables.
- An updated version of the GeoTools spreadsheet package for assessing geomorphic response.

These tools, in combination with existing tools, have the potential to advance hydromodification management by:

- Providing a physical basis for making predictions of stream response to watershed development.
- Assessing alternative future states of streams under different management scenarios.
- Avoiding one-size-fits-all solutions through:
 - Improved prediction of relative magnitude of potential channel change and proximity to response thresholds; and

- Tailoring mitigation strategies to streams with different levels of susceptibility.

Statistical models developed in this study indicate that the magnitude of channel enlargement and overall risk of channel instability are highly dependent on the ratio of post-to pre-urban sediment-transport capacity over cumulative duration simulations of 25 years. This ratio is often termed the *erosion potential (Ep)* or *load ratio (Lr)* and is a better predictor of long-term channel response than stream discharge. In addition, hydraulic variables (such as *Ep*, shear stress, or stream power) provide a “common currency” for managing erosion and associated effects that can be applied across many streams in a region. *Overall, the enlargement models point to the importance of balancing the post-development sediment transport to the pre-development setting over an entire range of flows rather than a single flow in order to reduce the risk of adverse channel responses to hydromodification.*

As with modeling, management strategies should also address the complexity of processes that affect stream response to hydromodification through application of a broad suite of management strategies beyond traditional site-based flow control. The foundation of any hydromodification management approach should be a watershed-scale analysis of existing and proposed future land uses and stream conditions that identifies the relative risks, opportunities, and constraints of various portions of the watershed. Site-based control measures should be determined in the context of this analysis.

Clear objectives should be established to guide management actions. These objectives should articulate desired and reasonable physical and biological conditions for various reaches or portions of the watershed. Management strategies should be customized based on consideration of current and expected future channel and watershed conditions including constraints that may limit the ability to apply certain approaches (e.g., existing development and channelization). A one-size-fits-all approach should be avoided.

An effective management program will likely include combinations of on-site measures (e.g., low-impact development techniques), in-stream measures (e.g., stream habitat restoration), and off-site measures. Off-site measures may include compensatory mitigation measures at upstream locations that are designed to help restore and manage flow and sediment yield in the watershed. To address existing, legacy and anticipated future effects, management approaches will need to focus on controlling erosion, deposition, and planform change as well as restoring watershed processes that ensure movement of water and sediment in ways that help maintain the dynamic equilibrium of stream channels. Such process-based management actions include:

- Protecting and restoring coarse sediment-supply areas.
- Maintaining and sediment transport capacity through critical stream reaches.
- Protecting and restoring floodplain connections and infiltration areas adjacent to channels.

Modeling and management programs should be connected to robust monitoring that can provide data to calibrate, test, and refine models and improve management approaches and the empirical basis upon which they are constructed.

The majority of criteria in this example suggest that a restoration endpoint is appropriate for this stream reach.	67

1.0 INTRODUCTION AND PURPOSE OF THE DOCUMENT

Hydromodification management is aimed at addressing issues of excessive erosion or deposition in channels and the associated geomorphic changes. The evolution of stormwater management beyond solely focusing on water chemistry is an important step forward in holistic efforts to protect the physical, chemical, and biological integrity of water courses. However, current approaches to hydromodification have been limited to managing only runoff, only at the site of new or re-developments, and without a watershed context. This approach has been shown to be insufficient to fully address hydromodification impacts in other regions (Booth and Jackson, 1997; Maxted and Shaver, 1999). Moreover, the focus on new and redevelopment does not include mechanisms to address legacy effects that may be affecting channel conditions. Present understanding of the causes and effects of urbanization suggest that site-based runoff control must be expanded to include integrated flow and sediment management at the watershed scale, along with targeted stream corridor/floodplain restoration (National Research Council (NRC), 2009; Stein *et al.*, 2012).

Hydromodification management approaches should be selected and designed to protect and restore agreed upon or designated beneficial uses and overall receiving water conditions, *by maintaining or reestablishing the watershed processes that support those conditions*. “Restoration” does not imply the return to a pre-development condition; instead, it may be defined as assisting the establishment of improved hydrologic, geomorphic, and ecological processes in a degraded watershed system (Wohl *et al.*, 2005). Achieving this goal will require that hydromodification management strategies be broadly considered beyond the location of individual projects and operate across programs beyond those typically regulated by National Pollutant Discharge Elimination System (NPDES)/MS4 requirements. Successful strategies will need to be developed, coordinated, and implemented through land use planning, non-point source runoff control, Section 401 Water Quality Certifications and Waste Discharge Requirement programs, in addition to traditional stormwater management programs.

A technical workgroup commissioned by the State Water Resources Board produced a broad set of recommendations for watershed-scale hydromodification management as part of their Technical Report #667 *Hydromodification Assessment and Management in California* (Stein *et al.*, 2012). The proposed management framework included on-site actions, floodplain management, and in-stream restoration. The goal of this document is expand on the recommendations from Stein *et al.* (2012) and provide a more detailed roadmap for 1) evaluating the efficacy of existing modeling tools in support of hydromodification management, and 2) selecting a suite of management measures at the appropriate scale and intensity. As such, the report is divided into two sections. Section 2 provides an overview of available modeling tools (including novel models developed in this project), and Section 3 provides a broad perspective on decision-making approaches for selecting hydromodification management measures. Both sections are intended to provide a set of potential tools and approaches that can be applied based on individual needs, stream conditions, and priorities. The approaches are not intended to be prescriptively used in all instances.

2.0 SUMMARY OF AVAILABLE TOOLS

Watershed urbanization alters natural hydrologic storage processes and leads to increased runoff volumes and rates with consequent increases in erosion and sedimentation potential if left unmitigated. In many southern California watersheds, altered flows of water and sediment resulting from urbanization and other land use changes (i.e., hydromodification) have resulted in channel incision, widening, and other forms of stream instability, as well as loss of riparian functions and connectivity. Even where interactions between climate and land use changes do not result in significant increases in upslope erosion, altered runoff processes may accelerate channel erosion and negatively affect water quality both upstream and downstream of a localized disturbance. The adverse impacts of hydromodification include threats to property and infrastructure, reduced habitat for aquatic life, increased water treatment costs, and diminished reservoir capacity.

Hydromodification results in variable hydrologic, geomorphic, and ecologic responses depending on site-specific factors like the connectivity of impervious areas and stormwater drainage systems, watershed soil characteristics, and the inherent resistance of stream channels to increased erosive forces. Characterizing, predicting, and managing the complex and multifaceted effects of hydromodification is therefore challenging, and there is no single model or predictive assessment tool that can answer the basic questions that are increasingly confronted by managers. These questions include:

- To what extent are patterns of stream flow altered by urban development?
- How do streamflow alterations relate to channel erosion, enlargement, and instability?
- In what ways and how much are the channel and its physical structure likely to respond after development – a little or a lot?
- Do different kinds of streams require different kinds of best management practices (BMPs) to protect channel structure and processes?
- What are reasonable expectations for effects of individual or combinations of BMPs, i.e., how can the location and type of BMP(s) relate to changes in channel structure, stability or recovery?
- What are reasonable expectations for achieving restoration based on specific conditions in a watershed?

Despite the plethora of existing tools and models that are relevant to hydromodification analysis and management (e.g., US Environmental Protection Agency (USEPA, 2007)), most predictive assessments of hydromodification impacts and analyses supporting site design decisions and mitigation activities currently rely on a few relatively-simplistic tools and models. For example, new developments may be required to match pre-development peak discharges for certain design storms or across some portion of a flow-duration curve regardless of the type of receiving stream (e.g., a sand bed vs. a boulder bed). Although uncomplicated and widely transferable approaches for minimizing the impacts of hydromodification are highly desirable from a practical standpoint, they may not sufficiently control the post-development discharges across the full spectrum of erosive flows as defined by the boundary conditions and inherent susceptibility of the receiving streams (both on-site and nearby). Therefore, there is a need for identifying modeling and assessment approaches that better balance the need for simplicity with the need for adequately representing the stream system being managed.

There are currently a number of gaps in the typical modeling toolbox that is utilized in hydromodification management. These gaps include:

- Hydrologic prediction at ungauged sites;
- Channel evolution models that conceptualize the predominant geomorphic processes and thresholds in disturbed channels of a particular region;
- More detailed and physically-rigorous channel response tools that build on rapid field assessments;
- Spreadsheet tools that facilitate computation of geomorphic metrics such as erosion potential and effective discharge;
- Models to estimate reduction in sediment supply (and sediment type) from developed land surfaces;
- Probabilistic models of stream response that explicitly quantify uncertainty; and
- An assessment of whether mobile boundary hydraulic models are appropriate for predicting stream response in this region.

Finally, there is a parallel need for practical guidance that enables managers to better evaluate models and their appropriate uses. When reviewing modeling-based hydromodification studies prepared by consultants, managers are often confronted with questions such as:

- Is this model appropriate for the question(s) at hand?
- What are the key considerations associated with a particular tool (e.g., scale, vintage of data, parameterization, etc.)?
- What are the underlying assumptions about physical and hydrological processes that are used by the model?
- What information and data are sufficient to drive the model?
- What is the simplest model that will provide adequate prediction accuracy?
- What is level of certainty associated with the output?

This section of the report begins to address the broad question of “how do we begin to organize models in a way that is useful to managers for decision-making?” There are two target audiences: 1) those who will actually be doing hydromodification modeling and 2) those who must review their work. The specific aims of this section are to:

- Present a general framework for understanding the role of models in hydromodification management.
- Provide a concise evaluation of selected modeling tools that are most relevant to hydromodification management in southern California (while highlighting some of the modeling tools developed in this project) in terms of the types of management questions the tools can address, input data requirements, scale of application, etc.
- Put individual models into the broader context of some complementary sets or suites of tools that are important in hydromodification management.
- Discuss ongoing limitations, key uncertainties, and priorities for future model development.

This section of the report complements Southern California Coastal Water Research Project (SCCWRP) Technical Report #667 *Hydromodification Assessment and Management in California* (Stein *et al.*, 2012) by 1) providing more specific information on novel modeling tools that address some of the gaps in current modeling tool box, and 2) delving more into some practical considerations of how models can inform hydromodification management. The new modeling tools developed in this study are described and put into the context of existing tools in terms of the management questions they can inform, and practical considerations in application and interpretation.

2.1 A General Framework for Understanding Models in Hydromodification Management

In the context of hydromodification, tools and models are typically used to help answer one or more of the following questions involving an assessment of natural and human influences at various spatial and temporal scales:

- What is the present stability status of the stream system and what are the dominant processes and features within the system?
- How have past human influences affected the current state and future potential of the stream?
- What is the likely future trajectory of the stream in the absence of any changes in land use or mitigation measures (e.g., no action alternative)?
- How will the stream likely respond to alterations in runoff and sediment supply?
- What level of flow control or other mitigation measures are necessary to protect the receiving stream(s)?

Many studies have underscored the variability and complexity of relationships between watershed land use, hydrologic processes, and the physical and ecological conditions of stream systems. Clearly, the process of assessing stream condition and predicting future conditions is very challenging and subject to uncertainty. Therefore, it is important to understand the strengths and limitations of available tools, especially with respect to prediction uncertainty, so one can choose an appropriate model for the question at hand. In addition to prediction uncertainty, considerations in choosing a model for a particular application include appropriate spatial and temporal detail, cost of calibration and testing, meaningful outputs, and simplicity in application and understanding (National Research Council (NRC), 2001; Reckhow, 1999a,b).

Figure 1 presents an organizing framework developed as part of this study for understanding general types of available tools that may be applied in support of hydromodification management and policy development. Tools fall into three major categories: 1) descriptive tools, 2) mechanistic and empirical/statistical models that are used deterministically, and 3) probabilistic models/predictive assessments with explicitly quantified uncertainty. The organizing framework relates these categories to the types of questions the tools are designed to answer, specifically: characterization of stream condition, prediction of response, establishment of criteria/requirements, or evaluation of management actions. The framework also characterizes the tools according to the following features: intensity of resource requirements (i.e., data, time, cost), and the extent to which uncertainty is explicitly addressed. Subsequent portions of this section discuss each of the three major categories in turn, highlighting

examples of specific tools within each category with particular emphasis on new tools developed in this project.

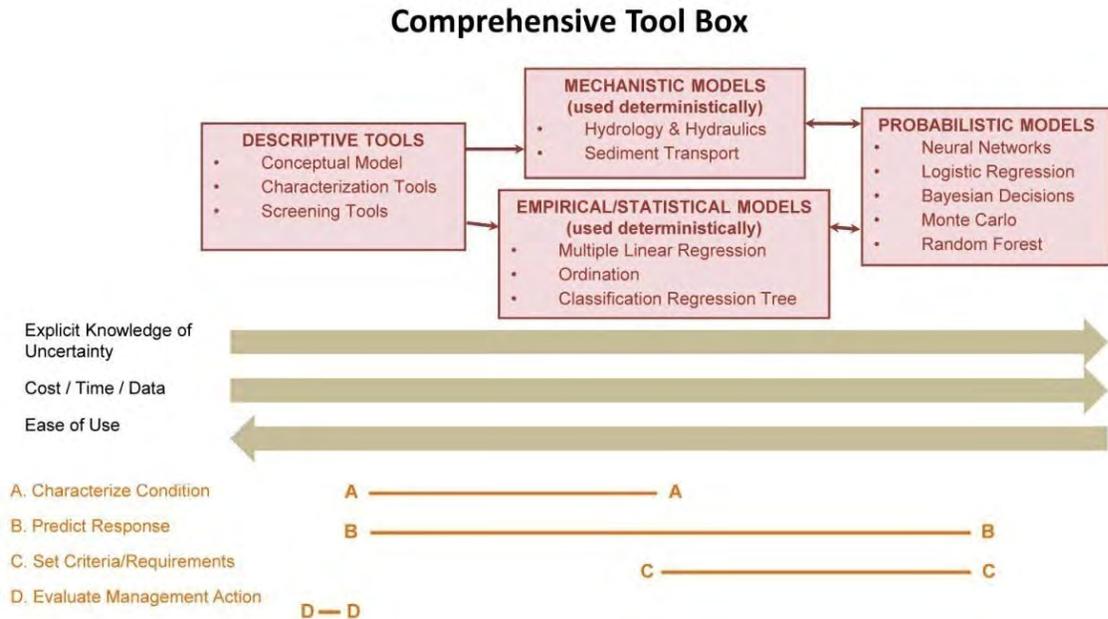

Figure 1. Organizing framework for understanding hydromodification assessment and management tools.

Tool selection should mirror the level of resolution that is required based on the point in the planning process. In the early stages of conducting an assessment, descriptive tools will be sufficient, but more precise tools will be required toward the design phase. Currently, most projects rely solely on deterministic models. However, given the uncertainty associated with predicting hydromodification impacts, probabilistic models should be incorporated into analysis and design, particularly where resource values or potential consequences of impacts are high.

"Given the uncertainty associated with predicting hydromodification impacts, probabilistic models should be incorporated into analysis and design, particularly where resource values or potential consequences of impacts are high."

2.1.1 Descriptive Tools

Descriptive tools include conceptual models, screening tools, and characterization tools. These tools are used to answer the question: *What is the existing condition of a stream or watershed?* Although descriptive tools are not explicitly predictive, they can be used to assess levels of susceptibility to future stressors by correlation with relationships seen elsewhere. The application of some type of descriptive tool, such as a characterization tool, is usually necessary before applying a deterministic model because descriptive tools aid in understanding the key processes and boundary conditions that may need to be represented in a more detailed model.

Conceptual models

A conceptual model, in the context of river systems, is a written description or a simplified visual representation of the system being examined, such as the relationship between physical or ecological entities, or processes, and the stressors to which they may be exposed. Conceptual models have been used to describe processes in a wide range of physical and ecological fields of study, including stream-channel geomorphology (Bledsoe *et al.*, 2008). For example, Channel Evolution Models (CEMs) are conceptual models which describe a series of morphological stages of a channel, either as a longitudinal progression from the upper to the lower watershed, or as a series at a fixed location over time subsequent to a disturbance. The incised channel CEM developed by Schumm *et al.* (1984) is one of the most widely-known conceptual models within fluvial geomorphology. This CEM documents a sequence of five stages of adjustment and ultimate return to quasi-equilibrium that has been observed and validated in many regions and stream types (American Society of Civil Engineers (ASCE), 1998; Simon and Rinaldi, 2000). Conceptual models in fluvial geomorphology also include planform classifications of braided, meandering and straight, and many other typologies that categorize streams by metrics such as slope, sinuosity, width-to-depth ratio, and bed-material size. The famous qualitative response model described by Lane's diagram (1955) is also a conceptual model.

A novel CEM for southern California

A new CEM with quantitative extensions was developed in this project to provide managers with a framework for understanding channel responses and rehabilitation alternatives in the region. The Schumm *et al.* (1984) CEM was modified for streams characteristic of southern California, including transitions from single-thread to multi-thread and braided evolutionary endpoints (Hawley *et al.*, 2012). The CEM is based on southern California data from 83 detailed channel surveys, hundreds of synoptic surveys, and historical analyses of aerial photographs along 14 reaches. The field surveys indicate that channel evolution sometimes follows the well-known sequence described by Schumm *et al.* (1984) for incising, single-thread channels; however, departures from this sequence are common and include transitions of single-thread to braided evolutionary endpoints, as opposed to a return to quasi-equilibrium single-thread planform. Thresholds and risk factors associated with observed channel response were also identified. In particular, distance to grade control and network position emerged as key controls on channel response trajectory.

Channels in southern California were observed to respond in ways that were at the same time analogous to and departed from the CEM of Schumm *et al.* (1984) (Figures 2 and 3). The fundamental importance of grade control in promoting the eventual return to quasi-equilibrium stages such as CEM Type IV or Type V is underscored in Figure 3, as incision-driven responses almost exclusively revolved around a hardpoint fulcrum. Self-stabilized reaches without a proximate grade control structure were rare, both during field reconnaissance and in our dataset (2 of 33 reaches, 3 of 83 sites). A similar trajectory was observed in a subset of braided systems which in some cases follow a sequence analogous to the Schumm *et al.* (1984) CEM for incising single-thread channels. This was especially true for the initial stages of incision (Phase B2), widening (Phase B3), and aggrading (Phase B4); which were primarily triggered by a base-level drop and the resulting headcutting. This was also caused by artificial increases in and/or concentration of flow from new stormwater outfalls or at road crossings via culverts

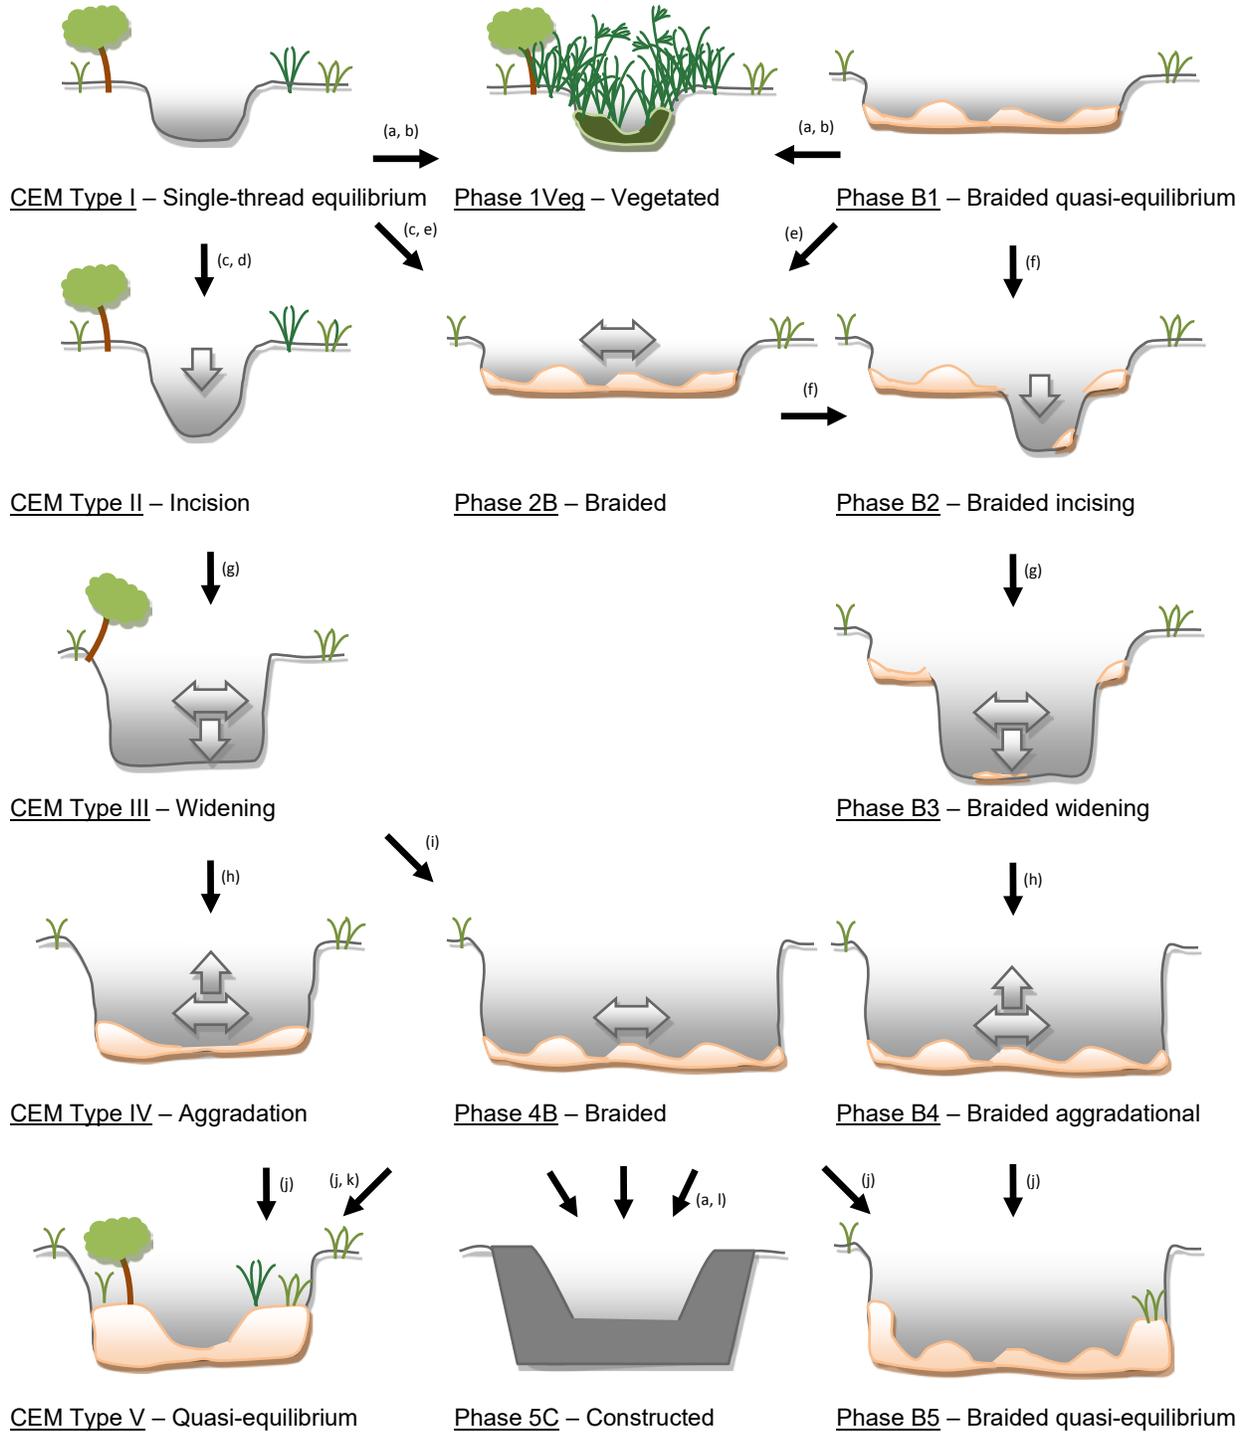

that concentrate the hydraulic energy but reduce sediment through flow, consistent with Chin and Gregory's (2001) observations in urbanizing ephemeral streams of Arizona. Indeed, this response sequence was routinely observed in predominantly rural watersheds (i.e., <1% imperviousness) where it seemed almost exclusively attributable to sediment discontinuities induced by channel fragmentation from infrequent human infrastructure, consistent with the widely-documented response of channel incision downstream of dams.

Although braided channels are widely considered less stable than single-thread channels (Ferguson, 1993; Hoey and Sutherland, 1991; Nanson and Croke, 1992; Schumm, 1977, 1981, 1985) with many classic examples of frequent and large shifts in channel position (Chien, 1961; Gole and Chitale, 1996), audits of historical aerial photography at several sites suggest that braided systems can also attain quasi-equilibrium for ca. 50 years in this region. This is consistent with recognition by other researchers that braiding can be an equilibrium channel state, given the necessary boundary conditions that result in no net change in the vertical or lateral dimensions over time (Chang, 1979; Klaassen and Vermeer, 1988; Leopold and Wolman, 1957; Parker, 1976; You, 1987).

CEM for Braided Channels

(Continued Next Page)

- (a) Can be preceded by any CEM stage
- (b) Induced by urban base flow such as lawn irrigation or wastewater treatment plant (WWTP) effluent
- (c) Relative erodibility of bed and bank material, available valley width, and downstream distance to hardpoint are key boundary conditions
- (d) Possible drivers include: S^+ , Q^+ , and/or Q_s^- basin
- (e) Possible drivers include: Q_s^+ basin, and/or Q^+ with Q_s^+ channel
- (f) Possible drivers include: S^+ , Q^+ , Q_s^- basin, and/or Q_s^- channel
- (g) Incision depth exceeds critical bank height for given angle (i.e., failure via mass wasting)
- (h) Q_s^+ channel exceeds transport capacity leading to toe protection of banks via aggradation
- (i) Q_s^{++} channel leads to excessive/irregular aggradation, flow deflection, and continued bank failure (bank strength and general cohesiveness of floodplain are key boundary conditions)
- (j) In most unstable southern California systems, a proximate downstream hardpoint (natural or artificial) is critical as a fulcrum for complex response sequences and the eventual return to quasi-equilibrium
- (k) Conceivable from any prior braided state; however, increasing braiding extent (i.e., degree of departure from reference channel width) would seem to decrease the probability of a return to single-thread quasi-equilibrium
- (l) Predominant terminal condition in urban/suburban channels of southern California

Figure 2. CEM of semiarid stream response to urban-induced hydromodification.

Notes:

- CEM stages in parentheses
- (a) the discontinuous effects of urban infrastructure such as scour downstream of grade control and increasing width-to-depth ratio moving downstream has also been observed in ephemeral Arizona streams in response to urbanization (Chin and Gregory, 2001)
- (b) natural (e.g., bedrock) or artificial (e.g., riprap/concrete) grade control

Figure 3. Profile view of one common evolution sequence in southern California channels in response to hydromodification.

A preliminary quantification of the CEM was performed using hydraulic and geomorphic metrics from all 83 study sites. Plotting the specific stream power (ω) of the 10-year flow vs. median grain size of bed material (d_{50}) by aggregated CEM stage (Figure 4) shows separation between states of dynamic equilibrium and disequilibrium. Single-thread channels in unconfined valleys that are in or approaching states of dynamic equilibrium (CEM Type I, Phase 1Veg, and CEM Types IV and V) tend to have the lowest specific stream power for a given bed-material resistance. Braided channels in states of dynamic equilibrium (Phase B1) typically have slightly higher erosive energy than single-thread equilibrium; however, they tend to have lower erosive energy than disequilibrium states (CEM Types II and III and Phases B2, 2B, and 4B).

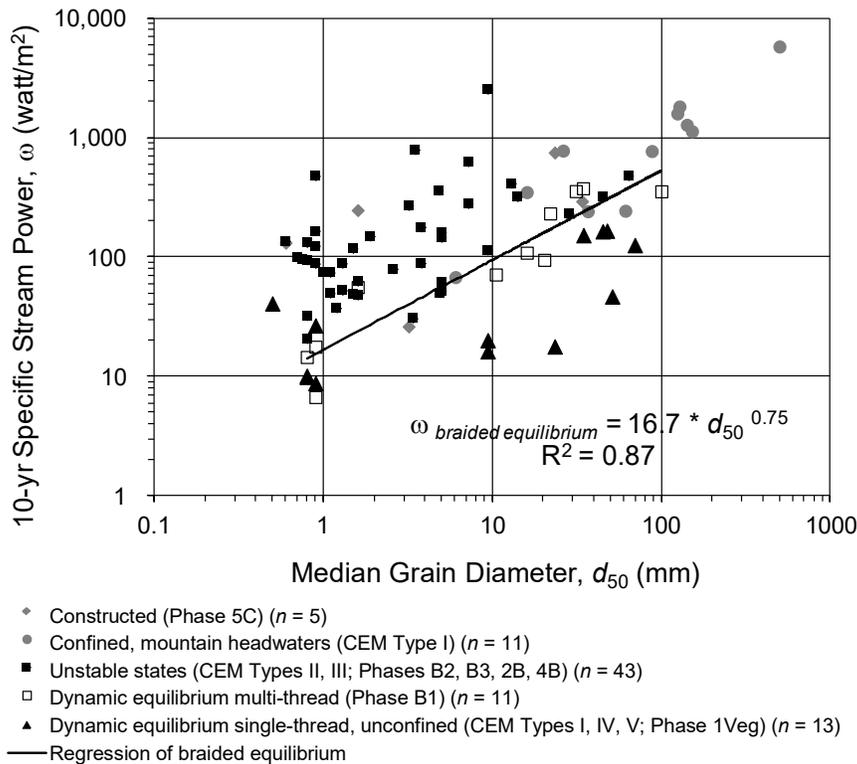

Figure 4. Ten-year specific stream power vs. median grain diameter by CEM stage of all 83 sites with superimposed power function of Phase B1 channels for visual separation.

Plotting the top width for a 10-year water-surface elevation vs. the 10-year peak flow for single-thread equilibrium systems in unconfined valleys and unconstructed settings resulted in a well-fit power function as a regional representation of forms sufficiently wide to dissipate energy without resulting in multiple flow paths (Figure 5). For reference, braided channels and incising channels (CEM Types II and III) are included in Figure 5, and indicated nearly-perfect separation over the power function. The relationship was then used to estimate a reference width (W_{ref}) for each site as a function of the 10-year peak discharge that is used to define a valley width index that was incorporated into the channel susceptibility screening tool that was developed in this project (Bledsoe *et al.*, 2012).

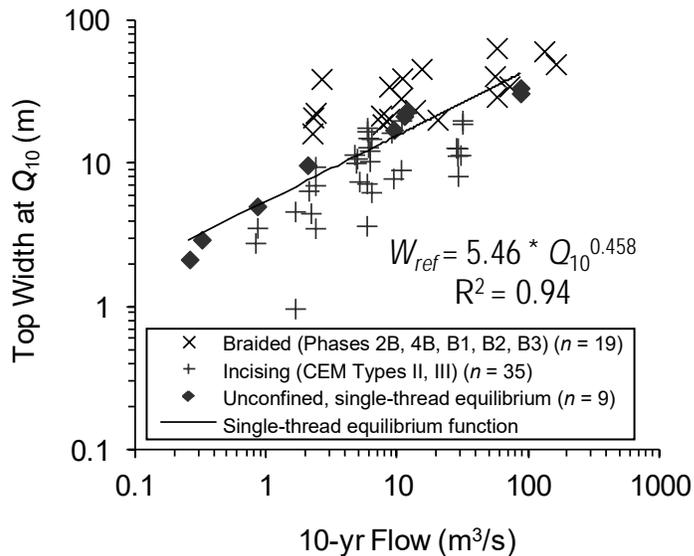

Figure 5. Top width vs. 10-year flow at unconfined, unconstructed single-thread equilibrium, braided, and incising sites with superimposed power function fitted to single-thread equilibrium sites.

The southern California CEM is a conceptual model that has utility for guiding management strategies as detailed in Hawley *et al.* (2012). For example, arresting channel instabilities in systems that are beginning to braid but have a width near W_{ref} , may have a higher likelihood of promoting a return to single-thread equilibrium than those systems with substantially greater widths. In this case, management of a new channel state may be more feasible than attempting to “restore” the channel to a prior state. With respect to incision, the CEM underscores the importance of employing rehabilitation measures before reaching critical bank height (prior to CEM Type III of the Schumm *et al.* (1984) model) in terms of cost and the disproportionate increase in channel erosion and downstream sedimentation/habitat degradation. In another example of using the CEM to guide rehabilitation, the distance away from the equilibrium lines in Figures 4 or I.5 could be used to help establish a threshold between channel restoration and “reconstruction to a new form” because it reflects likelihood of success. That is, CEM Type I could be targeted for preservation, restoration activities would be focused on Type II and early Type III channels, with the latter stages managed as a new form.

Regional CEMs can partially address the needs of the hydromodification management community by providing a framework for interpreting past and present response trajectories, identifying the relative severity of potential response sequences, applying appropriate models in estimating future channel changes, and developing strategies for mitigating the impacts of processes likely to dominate channel response in the future (Simon, 1995). CEMs can be useful in assessing channel instability both independently and as a part of a broader field-screening / reconnaissance tool. More details on specific channel trajectories and other aspects of the southern California CEM are provided in Hawley *et al.* (2012).

Characterization tools

Examples of characterization tools include baseline geomorphic assessments, river habitat surveys, and fluvial audits. A fluvial audit (Sear *et al.*, 1995, 2009) uses contemporary field surveys, historical map and documentary information, and scientific literature resources to gain a comprehensive understanding of a river system in its watershed context and how it arrived at its present state. Fluvial audits, along with watershed baseline surveys are a standardized basis for monitoring change in fluvial systems. These types of comprehensive assessments are comprised of numerous, more detailed field methodologies, such as morphologic surveys, discharge measurements, and estimates of boundary material critical shear strength through measurements of resistance (for cohesive sediments) or size. Baseline assessments may also draw on empirical relationships such as sediment-supply estimation models to explain stream responses to past watershed disturbances.

Screening tools

Screening tools can be used to predict the relative severity of morphologic and physical-habitat changes that may occur due to hydromodification, as a critical first step toward tailoring appropriate management strategies and mitigation measures to different geomorphic settings. The practical need for rapid assessments in stream management have prompted many efforts to develop qualitative or semi-quantitative methods for understanding the potential response trajectories of channels based on their current state.

Most screening-level tools for assessing channel instability and response potential, especially in the context of managing bridge crossings and other infrastructure, have borrowed elements of the CEM approach and combined various descriptors of channel boundary conditions and resisting vs. erosive forces. For example, Simon and Downs (1995) and Johnson *et al.* (1999) developed rapid assessment techniques for alluvial channels based on diverse combinations of metrics describing bed material, CEM stage, existing bank erosion, vegetative resistance, and other controls on channel response. Although based on a strong conceptual foundation of the underlying mechanisms controlling channel form, these tools were developed with goals and intended applications (e.g., evaluating potential impacts to existing infrastructure such as bridges or culverts) that differ somewhat from what is needed by current hydromodification management programs.

This project has resulted in a general framework for developing screening-level models that help assess channel susceptibility to hydromodification, and a new region-specific tool for rapid, field-based assessments in urbanizing watersheds of southern California (Bledsoe *et al.*, 2010, 2012). The criteria used to assign susceptibility ratings are designed to be repeatable, transparent, and transferable to a wide variety of geomorphic contexts and stream types. The assessment tool is structured as a decision tree with a transparent, process-based flow of logic that yields four categorical susceptibility ratings through a combination of relatively simple but quantitative input parameters derived from both field and geographic information system (GIS) data. The screening rating informs the level of data collection, modeling, and ultimate mitigation efforts that can be expected for a particular stream-segment type and geomorphic setting. The screening tool incorporates various measures of stream bed and bank erodibility, probabilistic thresholds of channel instability and bank failure based on regional field data,

integration of rapid field assessments with desktop analyses, and separate ratings for channel susceptibility in vertical and lateral dimensions.

This project has also produced a screening-level model that predicts changes in post-development sediment delivery based on watershed analyses of “Geomorphic Landscape Units” (GLUs) in a GIS (Booth *et al.*, 2010). A GLU analysis integrates readily-available data on geology, hillslope, and land cover to generate categories of relative sediment production under a watershed’s current configuration of land use. Those areas subject to future development are identified, and corresponding sediment-production levels are determined by substituting developed land cover for the original categories and reassessing the relative sediment production. The resultant maps can be used to aid in planning decisions by indicating areas where changes in land use will likely have the largest (or smallest) effect sediment yield to receiving channels.

2.1.2 Mechanistic and Empirical/Statistical Models with Deterministic Outputs

Mechanistic/deterministic models are simplified mathematical representations of a system based on physical laws and relationships. Empirical/statistical models describe the extent to which variation in output can be explained by (associated with) input variables. Both types of models are typically used to generate a single output or answer for a given set of inputs (despite the fact that statistical models are usually quite amenable to producing distributions of outputs). These tools can be used to help answer such questions as: *What are the expected responses in the stream and watershed given some future conditions? What criteria should be set to prevent future hydromodification impacts?* However, hydromodification modeling embodies substantial uncertainties in terms of both the forcing processes and the stream response. Deterministic representations of processes and responses can, therefore, mask uncertainties and be misleadingly precise, unless prediction uncertainty is explicitly characterized.

Hydrologic models

These models are used to simulate watershed hydrologic processes, including runoff and infiltration, using precipitation and other climate variables as inputs. Some models, such as the commonly-used Hydrologic Engineering Centers (HEC) – Hydrologic Modeling System (HMS), can be run for either single-event simulations or in a continuous-simulation mode which tracks soil moisture over months or years. Single-event simulations are focused on producing the hydrograph generated by individual storms, such as the 2-year flood or a less frequent flood event. In contrast, continuous simulations provide an unbroken series of discharges at daily or sub-daily (e.g., 15-min) time steps over a period of years to decades. Other hydrologic models that are commonly used for event-based and continuous simulation modeling include Hydrologic Simulation Program Fortran (HSPF) and Storm Water Management Model (SWMM). It is widely accepted that continuous simulation modeling, rather than event-based modeling, is required to assess the long-term changes in geomorphically-significant flow events (Booth and Jackson, 1997; Roesner *et al.*, 2001) that are critical in designing hydromodification mitigation strategies.

Several HSPF-based continuous-simulation models with standardized parameters have been developed specifically for use in hydromodification planning. These include the Western Washington Hydrology Model (WWHM) and the Bay Area Hydrology Model (BAHM). Hydromodification Management Plans (HMPs) in Contra Costa County, San Diego County, and Sacramento County have developed sizing

calculators for BMPs based on modeling done using HSPF models. To illustrate the point about uncertainty in mechanistic models, HSPF contains approximately 80 parameters, only about 8 of which are commonly adjusted as part of the calibration process.

Hydraulic models

These models are used to simulate water-surface profiles, shear stresses, stream power values, and other hydraulic characteristics generated by stream flow, using a geometric representation of channel segments. The industry standard 1-dimensional hydraulic model is the HEC – River Analysis System (HEC-RAS).

Coupled hydrologic and hydraulic models

These models represent a valuable tool in hydromodification management. Because the streamflow regime interacts with its geomorphic context to control physical habitat dynamics and biotic organization, it is often necessary to translate discharge characteristics into hydraulic variables that provide a more accurate physical description of the controls on channel erosion potential, habitat disturbance, and biological response. For example, a sustained discharge of 100 cfs could potentially result in significant incision in a small sand-bed channel, but have no appreciable effect on the form of a large channel with a cobble bed. By converting a discharge value into a hydraulic variable (common choices are shear stress, or stream power per unit area of channel relative to bed sediment size), a “common currency” for managing erosion and associated effects can be established and applied across many streams in a region. Such a common currency can improve predictive accuracy across a range of stream types. As opposed to focusing on the shear stress or stream power characteristics of a single discharge, it is usually necessary to integrate the effects of hydromodification on such hydraulic variables over long simulated periods of time (on the order of decades) to fully assess the potential for stream channel changes. By using channel morphology to estimate hydraulic variables across a range of discharges, models like HEC-RAS provide a means of translating hydrologic outputs from continuous simulations in HEC-HMS, SWMM, or HSPF into distributions of shear stress and stream power across the full spectrum of flows.

“By converting a discharge value into a hydraulic variable (common choices are shear stress, or stream power per unit area of channel relative to bed sediment size), a “common currency” for managing erosion and associated effects can be established and applied across many streams in a region.”

Sediment-transport models

These models such as HEC-6T, the sediment-transport module in HEC-RAS; CONservational Channel Evolution and Pollutant Transport System (CONCEPTS); MIKE 11; and FLUVIAL12 use sediment-transport and supply relationships to simulate potential changes in channel morphology (mobile boundary) resulting from imbalances in sediment continuity. This means that hydraulic characteristics are calculated as channel form and cross section evolve through erosion and deposition over time. Such models have high mechanistic detail but are often difficult to apply effectively. Although it is not a

mobile boundary model, the SIAM (Sediment Impact Analysis Method) module in HEC-RAS represents an intermediate complexity model designed to predict sediment imbalances at the stream network-scale and to describe likely zones of aggradation and degradation.

In this project, we evaluated the potential applicability of various movable bed and/or boundary models, including HEC-RAS (Brunner, 2008), CONCEPTS (Langendoen, 2000), and FLUVIAL12 (Chang, 2006) to predicting channel response to hydromodification in southern California. The tests involved modeling a prismatic floodplain with channel geometry, bed slope, and bed gradation corresponding to the Hasley Canyon study site in Orange County which represents a braided channel with a bed slope of 0.0258 and a median grain size of 1.6 mm. These tests indicated that mobile boundary hydraulic models are generally difficult to apply and have high prediction uncertainty due to flows near critical, split flow conditions, and lack of fidelity to complex widening, bank failure, and bed-armoring processes (Dust, 2009). For example, normal depth computations for the downstream-most cross section at the Hasley Canyon study site indicated that the Froude number ranges from approximated 0.97 to 1.14 for estimated flows corresponding to the 2- through 100-year events. These models are designed for sub-critical flows and it is common for such near-critical flows to produce numerical instabilities. Our extensive field reconnaissance indicates that armoring and channel widening resulting from both fluvial erosion and mass-wasting processes are key influences on channel response in southern California, and these processes are not well-represented and constrained in current mobile boundary models. Sediment transport rating curves based on field measurements have the potential to improve the efficacy of these models, especially for lower energy, single thread channels that are primarily vertically adjustable.

"These tests indicated that mobile boundary hydraulic models are difficult to apply and have high prediction uncertainty due to flows near critical, split flow conditions, and lack of fidelity to complex widening, bank failure, and bed-armoring processes."

Regime diagrams

The relationship between inflowing water and sediment loads and equilibrium channel dimensions can be described mechanistically by combining several governing equations including conservation of mass, conservation of momentum, flow resistance, and sediment transport. Analytical solutions to this system of governing equations can be summarized in a variety of ways, including charts that express channel slope and dimensions in relation to inflowing discharges of water and sediment. This project has developed a set of "regime diagrams" for assessing the potential direction and relative response of channel geometry to long-term changes in discharge and sediment supply due to hydromodification. A regime diagram is a plot of physical control variables overlain with isoclines of geometric parameters for the purpose of assessing potential channel response. *The diagrams are physically-based but designed to provide managers with a relatively simple form of output from analytical channel design models. Managers can use these diagrams to examine the channel dimensions and slope predicted the deterministic models described above without performing additional modeling.* In developing the regime diagrams, we stratified the channel types of study region into three general types (Figure 6):

1. Live-bed, sand-dominated channels,
2. Mixed-bed, gravel channels with considerable sand content, and
3. Cobble-bed channels with some gravel and sand content.

and selected governing equations that are well-suited to each geomorphic setting (Figure 7).

Figure 6. Examples of the 3 geomorphic types from southern California (courtesy of Hawley, 2009).

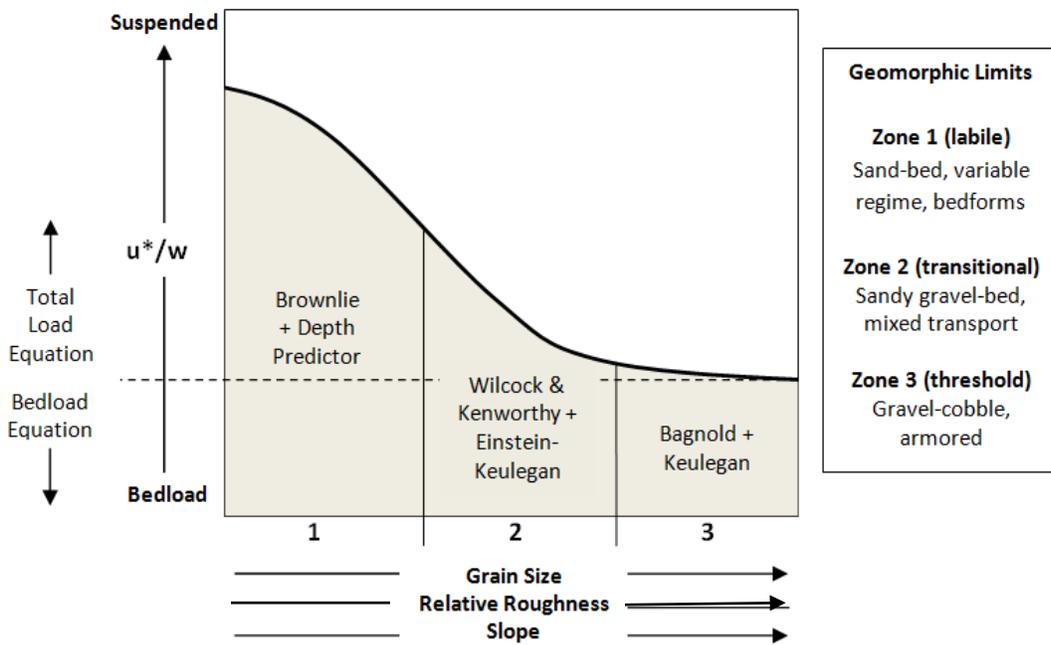

Figure 7. Geomorphic types used in this study. Labile, transitional, and threshold are terms used by Church (2006) to describe the hydraulic and sediment-transport processes occurring within each type.

Several regime diagrams were developed to provide an additional line of evidence describing the effect of long-term alterations of channel-forming discharge and the inflowing sediment concentration at that discharge on channel geometry (Figure 8). Separate diagrams have been developed for each geomorphic type using sediment-transport and flow-resistance relationships that are appropriate for those conditions. These relationships were plotted on log-log scales to compare the equilibrium channel

geometry associated with wide ranges of discharge and sediment concentrations between channels. Each regime diagram contains a series of isoclines, each corresponding to select values of width, depth, and slope.

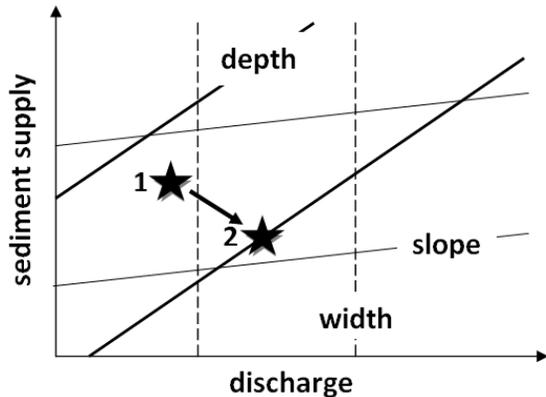

Figure 8. General framework of channel response diagrams. Long-term changes in discharge and sediment supply will be accompanied by a new equilibrium form (from plotting position 1 to 2).

Channel response diagrams for width, depth, and slope in Type 3 based on the Bagnold (1980) bedload transport equation are provided in Figures 9, 10, and 11, respectively. In these “relative response” diagrams, it is assumed that all variables are held constant except for the dependent parameter (width, depth or slope) and independent variables of relative discharge and sediment concentration. The initial state for each channel is indicated by the ratios of post-development to pre-development reference discharges of inflowing water and sediment (Q^* and Q_s^* , respectively) having values of 1 (no change). The post hydromodification state is typically represented by values of $Q^* > 1$ and $Q_s^* < 1$ (i.e., more runoff and less sediment); which translates into a new estimate of width, depth, and slope that theoretically represents the new equilibrium channel geometry. For instance, a Q^* of 2 and a Q_s^* of 0.8 would correspond to a doubling of the channel-forming discharge and a 20% reduction in sediment supply in an urbanizing watershed based on the Bagnold bedload relationship.

In the diagrams below (Figures 9 through 11), hypothetical relative changes in width, depth, and slope in response to changes in inflowing water and sediment discharges of +50% and -25%, respectively, are depicted by the dashed line labeled “regime.” For example, a more than five-fold change in width (departure from initial state of Q^* and Q_s^* equal 1; Figure 9) would be expected in the absence of concurrent slope and depth change. Similarly, the equilibrium slope required to balance inflowing water and sediment would be less than 60% of the pre-disturbance slope in the absence of width and depth change. These estimates bracket the maximum response that might be expected given a particular combination of altered discharge and sediment supply. In most instances, width, depth, and slope mutually adjust; however, in a stream with bedrock or other effective grade control, width increase would be expected to dominate the response to urbanization. In this case, the width equation would be most relevant. Alternatively, the response of a stream with highly-resistant banks and a sand bed without grade control would be expected to incise in its initial response to urbanization. In this case, the slope diagram would be most relevant. Such diagrams can also provide additional resolution to channel

susceptibility ratings in terms of expected relative changes in discharges of water and sediment. For example, this might be especially relevant for channels that rate from HIGH to VERY HIGH for lateral and/or vertical response in the SCCWRP screening tool. This would be accomplished by comparing the projected change in discharge of water and sediment based on watershed characteristics between streams in the same susceptibility class.

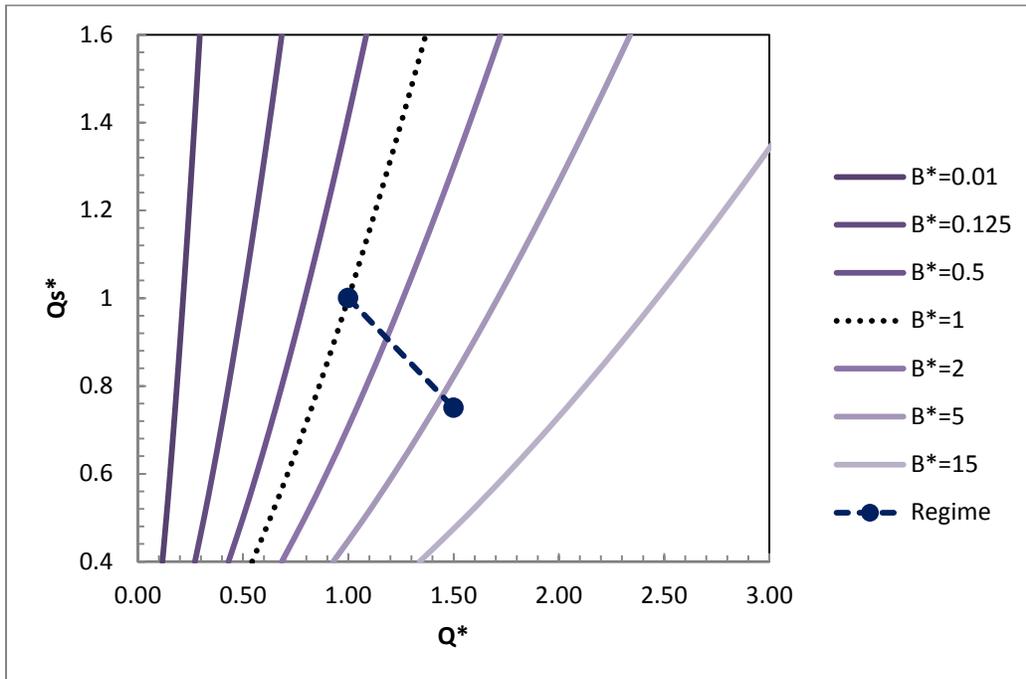

Figure 9. Maximum channel response diagram for width based on the quantitative approximation of Lane's balance using the Bagnold (1980) sediment-transport function. B^* represents an estimated maximum post-development width / pre-development width in the absence of mitigation.

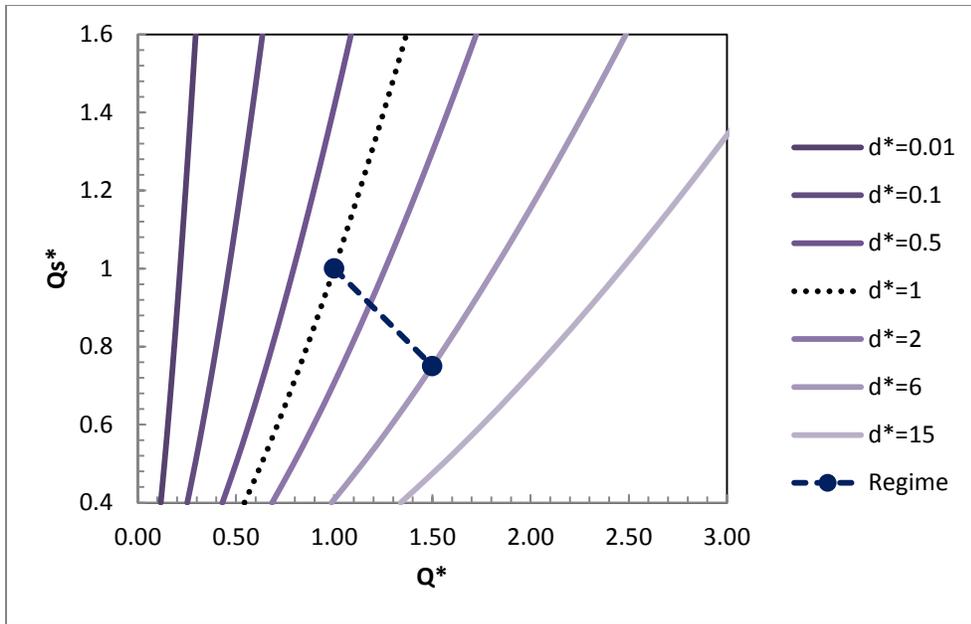

Figure 10. Maximum channel response diagram for depth based on the quantitative approximation of Lane's balance using the Bagnold (1980) sediment-transport function. d^* represents an estimated maximum post-development depth / pre-development depth in the absence of mitigation.

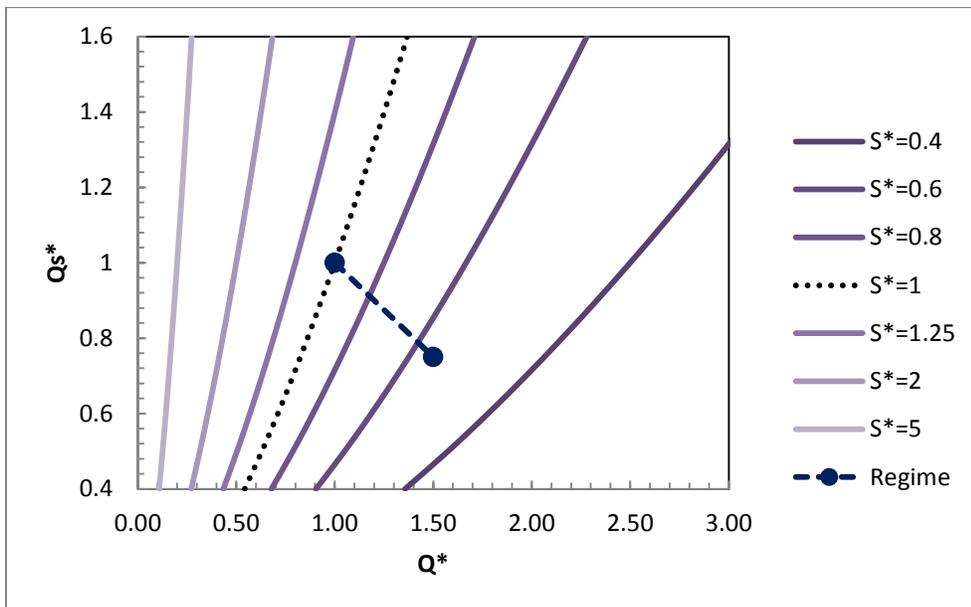

Figure 11. Maximum channel response diagram for slope based on the quantitative approximation of Lane's balance using the Bagnold (1980) sediment-transport function. S^* represents an estimated maximum post-development slope / pre-development slope in the absence of mitigation. For channels with lateral and vertical constraints, S^* values greater than one suggest aggradation, while those less than one suggest degradation.

Regime diagrams expressing absolute values of slope and depth in relation to channel-forming discharge and inflowing sediment concentration were developed by constraining width predictions based on field data collected in this study. Regime diagrams based on the median relationships for downstream hydraulic geometry in Types 1 and 2 are illustrated below (Figures 12 and 13, respectively). The resulting diagrams are unique in that they are based on regional stream width data stratified by type, as opposed to estimating widths by invoking a theoretical hypothesis like minimum stream power (Chang, 1988) or neglecting width by using a unit discharge of water and sediment (Parker, 1990).

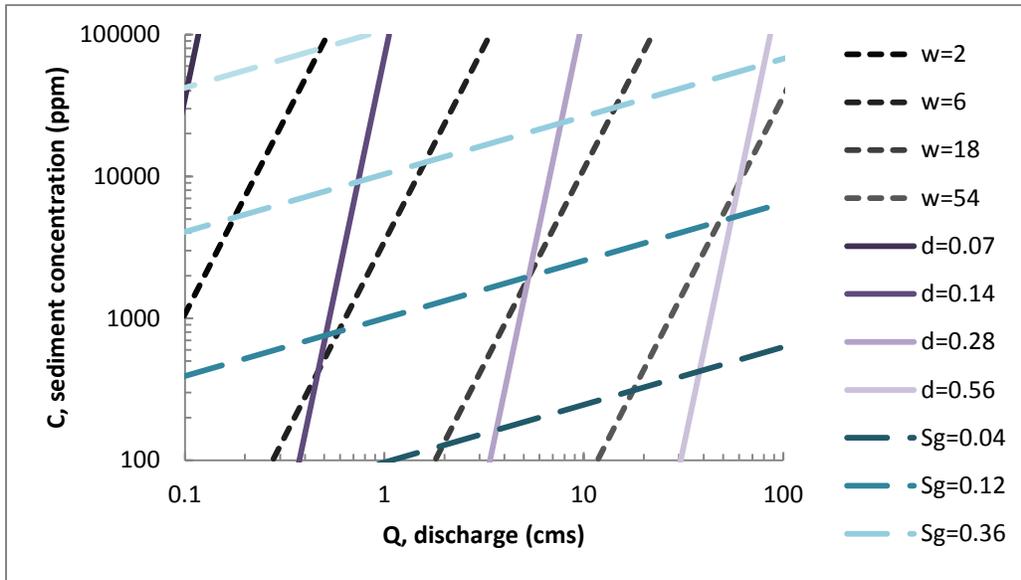

Figure 12. Type 1 regime diagram for absolute values of width, depth, and slope/ $d_{50}^{0.5}$ (S_g).

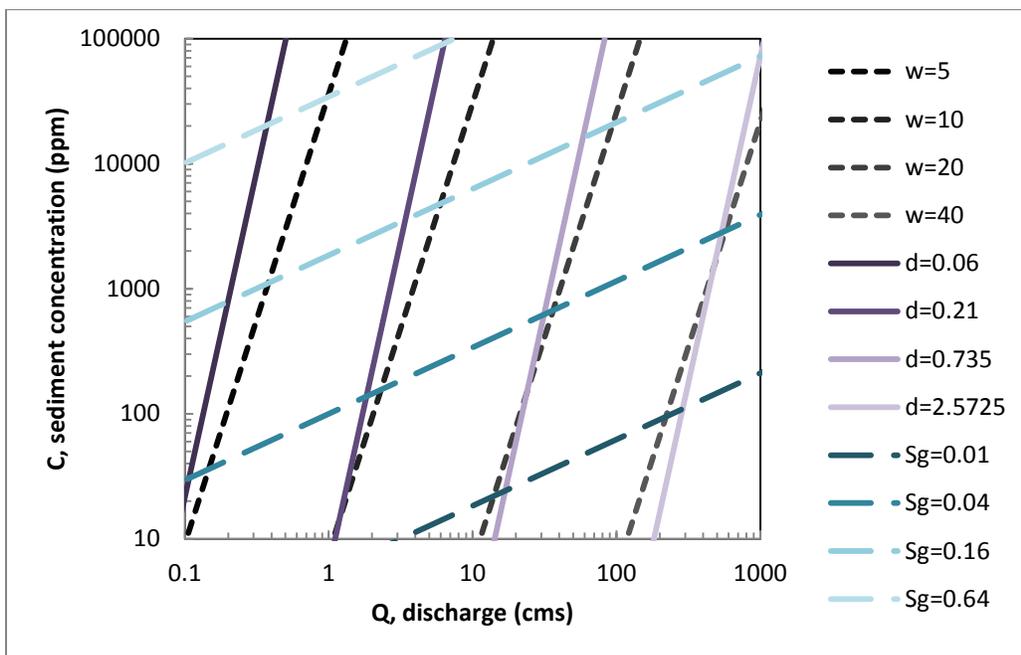

Figure 13. Type 2 regime diagram for absolute values of width, depth, and slope/ $d_{50}^{0.5}$ (S_g).

The regime diagrams based on field-calibrated widths are arguably more directly applicable to southern California than those previously available. Although regime diagrams for sand- and gravel-bed channels have already been developed (Buffington and Parker, 2005; Chang, 1980, 1985), they vary markedly in underlying framework, and were developed using different assumptions, parameters, and procedures that are not transferable across the broad spectrum of stream types encountered in southern California. This approach is unique in its development of a series of hydraulic geometry functions and regime diagrams based on a combination of regional channel data and governing equations categorized by channel type. This framework allows for comparisons between channel types, and allows users to assess the relative susceptibility of differing channel types to hydromodification. Another aspect of this approach is that it can be developed for any study area, and updated when new data are made available, as regional regression models for width and sediment gradation can be easily developed from existing or new field data. Although we selected large ranges of sediment size to represent transitional and threshold channels, the boundaries of geomorphic types are flexible based on field observations and measurements. The use of synthetic channel data and theoretical regression models increase the effective sample size, and models the mutual adjustment of geometric parameters based on the governing equations of flow continuity, flow resistance, and sediment-transport continuity.

Our approach has several limitations including the calibration ranges of the data used to develop the underlying regression models, several simplifying assumptions, and the inherent difficulty of estimating changes in sediment supply. For example, it was necessary in a few instances to extrapolate sediment transport functions beyond the range of field and laboratory conditions in which they were calibrated to accommodate large predicted increases in water and sediment supply from watersheds undergoing hydromodification. Moreover, our relatively small sample sizes have artificially limited the range of variability inherent to channel types observed within the study area. Spatial and temporal variability are also simplified through the use of reach-averaged characteristics and one-dimensional, steady, uniform flow at single return interval discharges. An assumption of rectangular channel geometry was used to simplify in-channel hydraulics and sediment transport analyses. We performed a sensitivity analysis that provided some insight into how the models respond to variability in input parameters; however, this analysis was not exhaustive. For example, in the development of diagrams for transitional channels, the median grain size of sand in the gravel matrix was fixed to 1 mm. This assumption was necessary to simplify an otherwise unwieldy sediment-transport function.

It is important to underscore that the diagrams were developed to examine trends in single-thread quasi-equilibrium channel geometry due to long-term changes in discharge and sediment supply from urbanizing watersheds. As such, the approach does not make short-term predictions of transient channel response, such as incision or widening, nor do the models describe the sequence of channel evolution stages that might occur during the time period that a watershed is urbanized and the receiving channels respond. Rather, the diagrams can be used to predict the likely ultimate channel response to changes in factors affected by development or mitigation (e.g., flow and sediment). The predicted channel responses are best utilized in a comparative sense to assess relative response potential between channels in different watershed settings. For example, one could compare the potential response of two streams that have different levels of estimated sediment supply and net change in

runoff potential based on the GLU method described above. Although these two streams might be in the same susceptibility class based on a rapid field screening, the regime diagrams would indicate non-linear differences in the potential magnitude of width, depth, and slope response to altered water and sediment inputs. Some users may find it difficult to understand separate predictions of ultimate channel depth versus slope, given that the channel depth to the top of bank will increase with incision (slope decrease) and decrease with aggradation that can result in a slope increase. The depth prediction represents the theoretical depth that would be necessary to balance sediment and water continuity if slope and width did not change. It is not the depth that results in response to some other slope change. *For practical applications, it is recommended that managers focus on relative potential changes in width and slope as the primary indicators of channel response potential.*

The regime diagrams are mechanistic models based on physical relationships governing hydrogeomorphic processes within the study area; however, the models should not be used in isolation without consideration of the cumulative error and uncertainty that are inherent. Given the necessary assumptions involved in their formulation and application, regime diagrams are not intended to be used as a stand-alone tool for predicting channel responses. Instead, they should be used in conjunction with other hydromodification tools described in this report to develop multiple lines of evidence for bracketing the possible range of channel responses to perturbations in discharge and inflowing sediment. Future versions of these tools could potentially be designed to explicitly replace single event descriptions of inflowing water and sediment with descriptors of long-term cumulative transport capacity and bed sediment supply rate. In either case, other modeling tools described below must be used to generate estimates of changes in inflowing water and sediment, and this remains the primary challenge (especially inflowing sediment) in applying these tools.

Empirical/statistical models

These models describe associations between response variables and predictor variables, and the extent to which variation in output can be explained by input data. In the context of hydromodification management, statistical models are developed to describe empirical relationships that help predict stream responses to stressors like increased streamflow volumes and rates. With sufficient data, statistical models can be developed to describe significant associations between land use change and hydrologic, geomorphic, and/or biological responses. Such relationships do not mechanistically link cause and effect but can nevertheless provide important evidence for making management decisions, including evaluating the performance of mechanistic models. For example, most lower-order streams affected by hydromodification are ungauged and streamflow characterization necessarily relies on modeling. Statistical models provide a relatively-simple alternative to rainfall-runoff modeling if there are comparable streamflow gages that can be extrapolated to an ungauged site and a truly continuous series of streamflows is not required. Statistical predictions of streamflow metrics in ungauged basins also support mechanistic modeling

Regime diagrams should do not make short-term predictions of transient channel response, such as incision or widening. Rather, the diagrams can be used to predict the likely ultimate channel response to changes in factors affected by development or mitigation (e.g., flow and sediment).

efforts by providing information that can be used for model testing when calibration data are not available. In this project, we developed regional statistical models of streamflow that support a wide range of hydromodification modeling efforts aimed at assessing channel susceptibility and predicting geomorphic response to urbanization (Hawley and Bledsoe, 2011). In particular, the regression models can be used to estimate changes in both peak flows and flow durations that result from unmitigated watershed urbanization. The prediction of pre- and post-development flow-duration curves at ungauged sites provides a relatively-straightforward means of estimating erosion potential metrics that can be used in probabilistic models of channel response.

Statistical models have also been used to explain variance in channel enlargement in response to hydromodification based on measures of watershed urbanization, erosive energy, and other factors. Such models sometimes include independent variables derived from the mechanistic models described above; however, a key difference is that statistical models are not designed to explicitly represent actual physical processes in their mathematical structure. Instead, these models simply express observed correlations between dependent and independent variables. Like mechanistic models, the output from these models is commonly treated deterministically as a precise answer for use in management decisions, despite the fact that estimates from most statistical models could be readily (and more realistically) expressed in terms of distributions or prediction intervals with a range of uncertainty. As part of this project, we developed multivariate regression models of cross-sectional channel enlargement at 61 sites in southern California. Results indicate that channel enlargement is highly dependent on the ratio of post- to pre-urban sediment-transport capacity over cumulative duration simulations of 25 years (load ratio, a.k.a. erosion potential, E_p), which explained nearly 60% of the variance (Tables 1 and 2 and Figure 14). A logistic regression analysis of the same sites (classified categorically as stable vs. unstable channels) with erosion potential as the sole predictor variable indicates that E_p values of 0.79, 1.0, 1.23, and 2.0 correspond to 10, 27, 50, and 92% risk of instability, respectively (Figure 15). Classification accuracies for stable and unstable sites were 93 and 73%, respectively. The appreciably high probabilities of instability associated with values of erosion potential near unity likely reflect the influence of decreased sediment delivery, i.e., matching the flow duration curve for a wide spectrum of erosive flows may not be sufficiently protective of channel stability when inflowing sediment loads are substantially decreased through impervious and other land use changes.

"Results indicate that channel enlargement is highly dependent on the ratio of post- to pre-urban sediment-transport capacity over cumulative duration simulations of 25 years (load ratio, a.k.a. erosion potential), which explained nearly 60% of the variance."

Table 1. Channel enlargement risk factors. Ranked in relative order of importance based on how well they explain changes in channel cross-sections over time.

Variable	Description	Qualitative Influence	Partial R ² [§]	
			n = 66	n = 61 [*]
Lr (Ep)	Sediment-transport capacity load ratio (erosion potential) between 25-yr developed and undeveloped DDF simulations: $L_{\text{developed}}/L_{\text{undeveloped}}$ (m ³ /m ³)	+	.28	.58
Imp	total impervious area as fraction of total drainage area (m ² /m ²)	+	.21	.56
D_{hp}/W₁₀	downstream distance to nearest 'hardpoint' (bedrock or artificial) scaled by top width at 10-yr flow (m/m). term goes to 0 if Lr < 1.20 for d₅₀ > 16 mm OR if Lr < 1.05 for d₅₀ < 16 mm	+	.32	.34
Chnlz	binary variable representing historic channelization along reach (0 = unchannelized, 1 = channelized)	+	.20	.01
Confined	binary variable representing valley confinement as defined as a Valley Width Index (VWI) threshold of 2 (0 = VWI > 2, 1 = VWI < 2)	-	.01	.02
Srf	average surface slope of watershed (m/m)	+	.02	.01
DD	drainage density: total stream length via National Hydrography Dataset (NHD) / total drainage area (km/km ²)	+	.01	.01
Veg	binary variable representing bank vegetation (0 = poor, 1 = dense)	-	.03	.01
Cohesion	binary variable representing relative bank cohesion (0 = low, 1 = high)	-	.01	.01

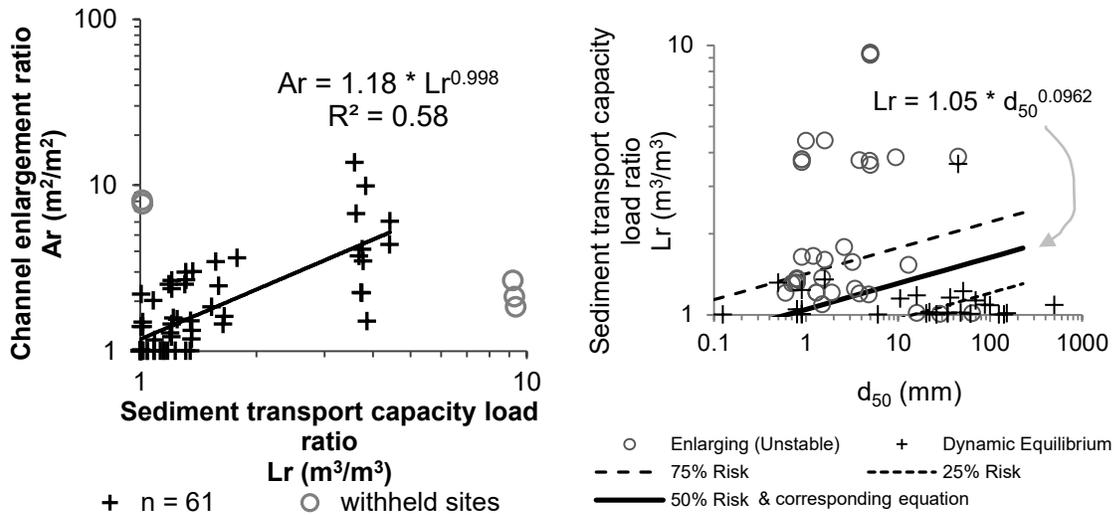

[§] typical partial R² based on model forward selection

^{*} withheld stream reaches where enlargement was primarily driven by historic channelization (San Antonio) or kept artificially low due to dense vegetation (Agua Hedionda); both factors were poorly distributed in our dataset

$Ar = 1.18 * e^{(11.0*Imp)}$	0.55	

[§] withheld stream reaches where enlargement was primarily driven by historic channelization (San Antonio) or kept artificially low due to dense vegetation (Agua Hedionda); both factors were poorly distributed in our dataset

(a) enlargement vs. erosion potential

(b) risk of enlargement associated with d_{50} and erosion potential

[§] based on the withholding of two stream reaches where enlargement was primarily driven by historic channelization (San Antonio) or kept artificially low due to dense vegetation (Agua Hedionda); both factors were poorly distributed in our dataset

Figure 14. Models of cross-sectional channel enlargement[§]: a) power regression of Lr vs. enlargement indicating that channel enlargement increases with increasing erosional potential, and b) multivariate logistic regression of stable vs. enlarged channels as a function of Lr and d_{50} . This model indicates increasing risk of enlargement with decreasing grain size and erosion potential (Hawley and Bledsoe, In Review).

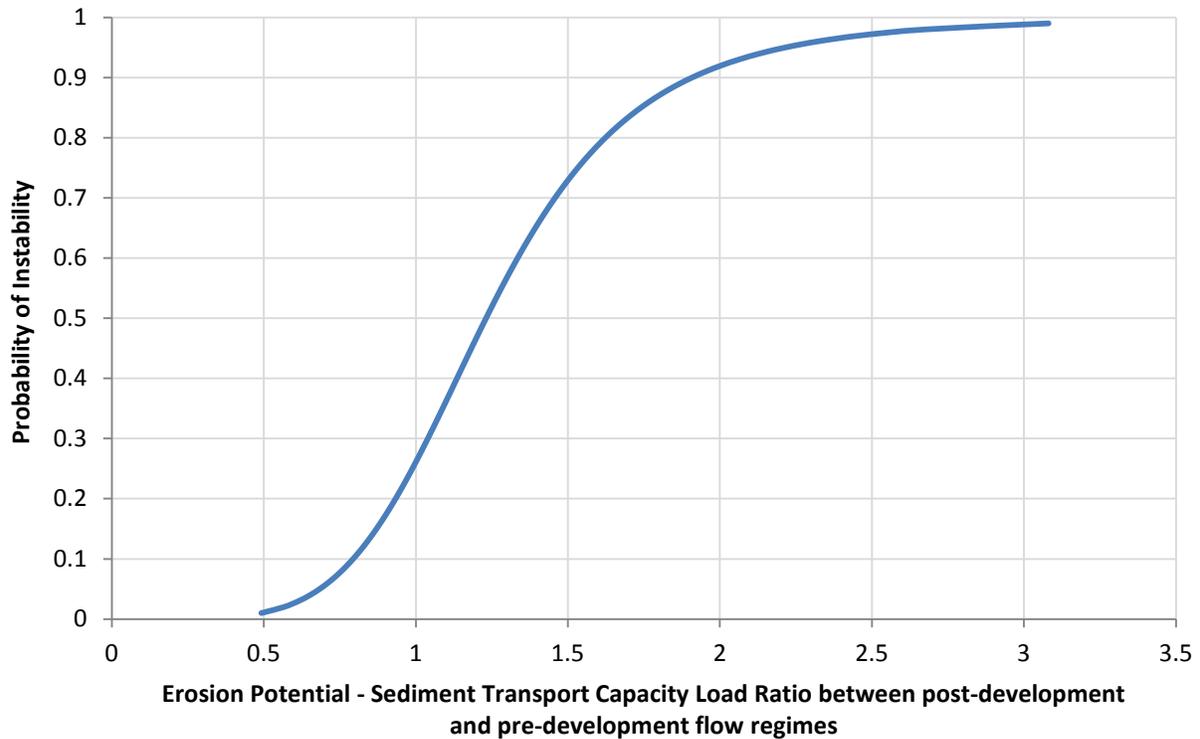

Figure 15. Logistic regression model based on classification of stable vs. unstable streams at 61 sites in southern California described by Hawley and Bledsoe (In Review) indicates increasing risk of channel instability with increasing erosion potential. The vertical axis represents the probability of stream instability which increases rapidly for channels with sediment-transport capacity increased by hydromodification.

Results consistently indicate that susceptibility tends to increase with increasing erosion potential and distance from a downstream hardpoint, and decreasing bed-material particle size. Most of the variance in cross-sectional channel enlargement could be explained by the downstream distance to a hardpoint and the cumulative sediment-transport imbalance quantified over 25-year simulations. For example, ~five-fold enlargement was correlated to $D_{hp}/W_{10} \sim 30$ and $Lr \sim 3.5$ (~15% imperviousness); ~two-fold enlargement would be expected with the same hardpoint distance and $Lr \sim 1.2$ (~5% imperviousness).

The models demonstrate that the risk of adverse morphologic channel responses is best reduced by minimizing increases in time-integrated sediment-transport capacity on future developments. This conclusion was further affirmed with statistically-significant ($p < 0.0001$) logistic-regression models based on erosion potential and d_{50} , which suggested that fine-grained systems, especially those with d_{50} less than 16 mm, have little capacity to resist any increases in sediment-transport potential. Thus, the statistical models point to the importance of balancing the post-development sediment transport to the pre-development setting over a ~25-year range of sediment-transporting flows rather than a single flow in order to reduce the risk of adverse channel responses to hydromodification. The primary step to achieving this criterion in management is matching the pre-development flow duration curve above the shear stress that mobilizes the most erodible channel boundary, which is often the bed material.

Integrative tools that support statistical models

Integrative tools are designed to combine hydrologic and geomorphic data to identify physically-based descriptors of channel-forming discharges, frequency distributions of stream power and shear stress, and cumulative sediment transport. In most instances, such tools are created by analysts in spreadsheet applications because there are very few “off-the-shelf” software packages that perform these types of calculations. One exception is GeoTools, an existing suite of analysis tools for fluvial systems written in Visual Basic for Applications (VBA) / Excel[®]. Based on flow time series and basic geomorphic data, GeoTools automates computation of numerous hydrologic, hydraulic, and geomorphic descriptors including effective discharge, sediment transport and yield, temporal distributions of hydraulic parameters (e.g., shear stress and specific stream power), cumulative erosion potential, channel stability indices, and over 100 flow regime metrics (Bledsoe *et al.*, 2007). GeoTools accepts input flow records in standard US Geological Survey (USGS) format and a variety of other formats and temporal densities. The package also serves as a post-processor for SWMM and HSPF / Better Assessment Science Integrating Point and Nonpoint Sources (BASINS) model output.

As newer versions of Excel[®] have become available since GeoTools was developed in Excel[®] 2003, some of the original functionality of GeoTools has not transferred due to changes in Excel[®] 2007 and 2010 (e.g., reference libraries and chart options in VBA). In this project, we updated GeoTools to make it fully functional in Excel[®] 2010. This facilitates the calculation of erosion potential and flow metrics, and allows users to readily generate several new charts related to effective discharge analysis and other analyses that combine continuous streamflow records and sediment-transport relationships (Figure 16). The erosion potential metrics output by GeoTools are a key input for the channel enlargement models developed in this study and the probabilistic models described in the next section.

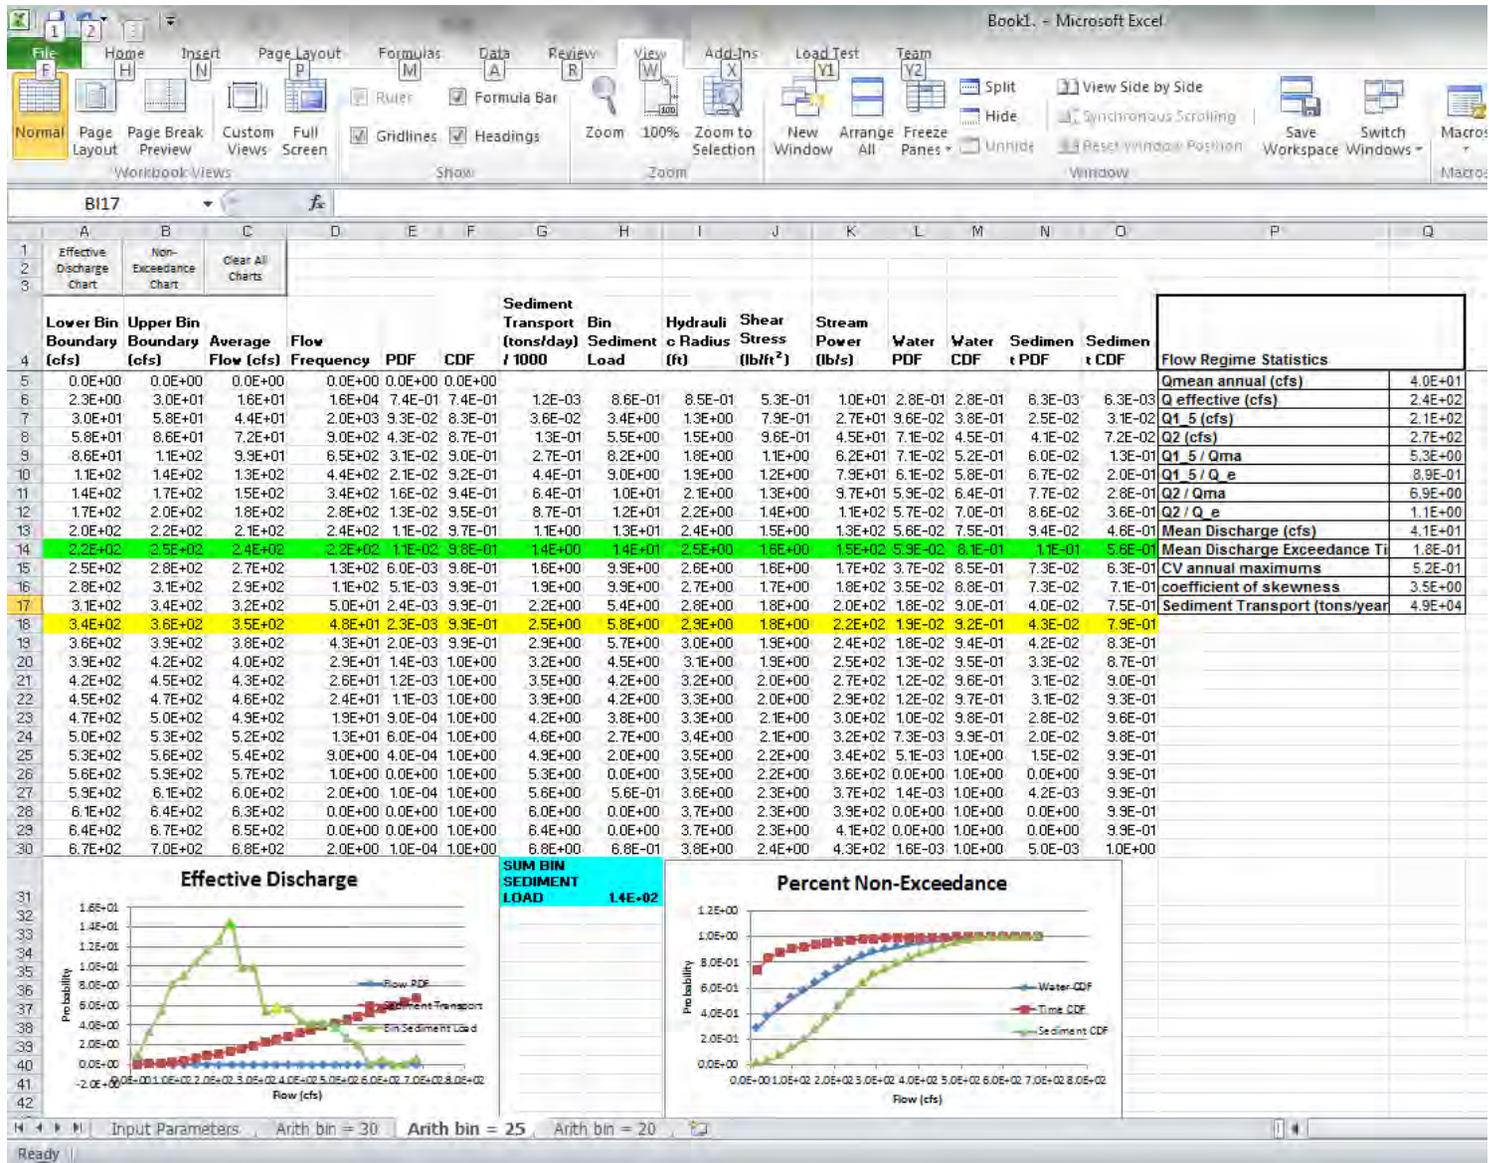

Figure 16. Example output from effective discharge / erosion potential module of GeoTools updated for Excel 2010.

2.1.3 Probabilistic / Risk-based Models

Probabilistic / risk-based models integrate many of the tools discussed above, using modeled changes in hydrology as input to hydraulic models, which in turn provide input to various types of statistical models to predict response. However, the predictions based on these inputs are not represented as deterministic outputs. Instead, the range of (un)certainty in the likelihood of the predicted response is explicitly quantified. Although not commonly used for hydromodification management at this time, there are well-established models of this type that are currently in use in other scientific disciplines. An example of a probabilistic approach that has been used for hydromodification management is a logistic regression analysis that was used to produce a threshold “erosion potential metric” that can be used to quantify the probability of a degraded channel state. More details on this approach are provided below in the section on suites of modeling tools.

In this project, we examined the use of General Regression Neural Network (GRNN) models to predict channel enlargement due to the effects of hydromodification on regional streams. Results indicated that this and other artificial neural network (ANN) modeling techniques represent a viable probabilistic modeling approach for hydromodification management. When applied to our field dataset, the GRNN models indicated that estimated increases in Q_2 , based on regional flood regression equations (Hawley and Bledsoe, 2011), consistently ranked as the most important predictor of channel enlargement despite the inclusion of a large pool of watershed and geomorphic descriptors at various spatial scales. The best models also consistently included key variables used in the SCCWRP Colorado State University (CSU) susceptibility screening tool such as distance to hardpoint, Valley Width and Valley Expansion Ratio that are not directly related to the extent of watershed development. Few attempts have been made to comprehensively model a broad set of parameters that influence geomorphic response in southern California streams, mostly due to the computational limitations of deterministic models and the relative simplicity of regression models. This project has shown that GRNNs can capture many of the non-linear relationships that influence hydromodification response in channels of southern California and provide quantitative estimates of change and the uncertainty associated with those estimates.

“When applied to our field dataset, the GRNN models indicated that estimated increases in Q_2 , based on regional flood regression equations, consistently ranked as the most important predictor of channel enlargement despite the inclusion of a large pool of watershed and geomorphic descriptors at various spatial scales.”

Like all models, GRNNs come with caveats and inherent weaknesses, such as, the choice of model inputs, network structures and internal model parameters, and method of pre-processing of model inputs (Maier and Dandy, 2000). Because most ANN models are data-driven (Chakraborty *et al.*, 1992) and are able to determine critical parameters, users tend to pay little attention to the selection of appropriate model inputs (Faraway and Chatfield, 1998). It is important to ensure that the model includes process-based surrogate measures of response drivers and mechanisms that can accurately represent the real system, and are not just built on available data. GRNNs rely on associations between target and predictor variables; therefore, the more process-based the predictor variables used, the less

complex a GRNN will need to be. For example, in this study the GRNN that was developed with the urban-amplified Q_2 required 25% fewer variables to match the performance of the higher recurrence interval flow models, which did not inherently reflect watershed imperviousness. Pre-processing for GRNN networks includes standardization to ensure all variables are treated equally (Maier and Dandy, 2000). Scaling the variables to fall within the limits of activation functions used in the outer layer is also recommended as a pre-processing step (Maier and Dandy, 2000; Minns and Halls, 1996). Nevertheless, GRNNs can help in support of rating channel susceptibility to hydromodification and identifying target variables for detailed data collection. In this way, GRNN can be used to support not only predictive modeling, but also to inform effective field monitoring and assessment programs. Overall, our results suggest that GRNN predictions can be used in concert with other tools to help inform management decisions, such as the need for flow duration based stormwater controls, and to tailor monitoring programs.

A probabilistic representation of possible outcomes also improves understanding of the uncertainty that is inherent in model predictions, and can inform management decisions about acceptable levels of risk.

2.2 Strengths, Limitations, and Uncertainties

The organizing framework shown in Figure 1 depicts the applicability of the three major categories of tools in support of various management actions. This section addresses a range of issues relating to strengths, limitations, and uncertainty of the tools discussed above. Detailed analysis of individual models is beyond the scope of this document, but *EPA/600/R-05/149* (Shoemaker *et al.*, 2005) contains an extensive comparison of functions and features across a wide range of hydrologic and hydraulic models.

General considerations

The well-known statistician George Box famously said that “all models are wrong, some are useful.”

The usefulness of a model for a particular application depends on many factors including prediction accuracy, spatial and temporal detail, cost of calibration and testing, meaningful outputs, and simplicity in application and understanding.

There is no cookbook for selecting models with an optimal balance of these characteristics. Models of stream response to land use change will always be imperfect representations of reality with associated uncertainty in their predictions. In addition to the prediction errors of standard hydrologic models, common limitations and sources of uncertainties include insufficient spatial and/or temporal resolution, and poorly-known parameters and

“Ultimately, the focus of scientific study in support of decision making should be on the decisions (or objectives) associated with the resource and not on building more-detailed models with the hope that they will provide the answers that elude us.”

...

“The predictive models that hold the most promise in hydromodification management are best thought of as predictive scientific assessments; that is, flexible, changeable mixes of small mechanistic models, statistical analyses, and expert scientific judgment.”

boundary conditions. Ultimately, the focus of scientific study in support of decision-making should be on the decisions (or objectives) associated with the resource and not on building more-detailed models with the hope that they will provide the answers that elude us. Each model has limitations in terms of its utility in addressing decisions and objectives of primary concern to stakeholders. Prediction error in terms of decision endpoints, not perception of mechanistic correctness, should be the most important criterion reflecting the usefulness of a model (NRC, 2001; Reckhow, 1999a,b). The predictive models that hold the most promise in hydromodification management are best thought of as predictive scientific assessments; that is, flexible, changeable mixes of small mechanistic models, statistical analyses, and expert scientific judgment.

Region-specific considerations

Because all models are vulnerable to improper specification and omission of significant processes, caution must be exercised in transferring existing models to new regional conditions. For example, mobile boundary hydraulic models are mechanistically detailed but not generally well-suited to many southern California streams given the prevalence of near-supercritical flow, braiding, and split flow. In addition, bed armoring and channel widening resulting from both fluvial erosion and mass-wasting processes are key influences on channel response in semiarid environments. These processes are not well-represented and constrained in current mobile boundary models. Accordingly, the appropriateness of existing models for addressing a particular hydromodification management question should be empirically tested and supported with regionally-appropriate data from diverse stream settings.

Sediment supply

As described above, a reduction in sediment supply to a stream may result in instability and impacts, even if pre- and post-land use change flows are perfectly matched. Thus, there is a need to develop management approaches to protect stream channels when sediment supply is reduced, and to refine and simplify tools to support these approaches. This continues to prove challenging because, the effects of urban development on sediment supply in different geologic settings are not well-understood and poorly represented in current models. As a starting point, models used to analyze development proposals that reduce sediment supply could be applied with more protective assumptions with respect to parameters and boundary conditions (inflowing sediment loads). Effects of altered sediment supply on stream response could be addressed in a probabilistic framework by adjusting conditional probabilities of stream states to reflect the influence of reductions in important sediment sources due to land use change.

Managing uncertainty

To date, hydromodification management has generally relied on oversimplified models or deterministic outputs from numerical models that consume considerable resources but yield highly uncertain predictions that can be difficult to apply in management decisions. Numerical models are nevertheless an important part of the hydromodification toolbox, especially in characterizing rainfall-response and hydraulic behavior over decades of land use change. It is challenging to rigorously quantify the prediction accuracy of these mechanistic numerical models; however, their utility can be enhanced by addressing prediction uncertainties in a number of ways (Cui *et al.*, 2011). Candidate models can, for

example, be subjected to sensitivity analysis to understand their relative efficacy for assessment and prediction of hydromodification effects. Moreover, it should also be demonstrated that selected models can reasonably reproduce background conditions before they are applied in predicting the future. Modeling results that are used in relative comparisons of outcomes are generally much more reliable than predictions of absolute magnitudes of response.

Hydromodification modeling embodies substantial uncertainties in terms of both the forcing processes and stream response. Deterministic representations of processes and responses can mask uncertainties and can be misleading unless prediction uncertainty is explicitly quantified. Errors may be transferred and compounded through coupled hydrologic, geomorphic, and biologic models. Accordingly, explicit consideration, quantification, and gradual reduction of model uncertainty will be necessary to advance hydromodification management. This points to two basic needs. First, there is a need to develop more robust probabilistic modeling approaches that can be updated and refined as knowledge increases over time. Such approaches must be amenable to categorical inputs and outputs, as well as combining data from a mix of sources including mechanistic hydrology models, statistical models based on field surveys of stream characteristics, and expert judgment. Second, the uncertainty inherent to hydromodification modeling underscores the need for carefully-designed monitoring and adaptive management programs.

"There is a need to develop more robust probabilistic modeling approaches that can be updated and refined as knowledge increases over time. Such approaches must be amenable to categorical inputs and outputs, as well as combining data from a mix of sources including mechanistic hydrology models, statistical models based on field surveys of stream characteristics, and expert judgment."

...

"The uncertainty inherent to hydromodification modeling underscores the need for carefully-designed monitoring and adaptive management programs."

A probabilistic / risked-based framework can provide a more rational and transparent basis for prediction and decision-making by explicitly recognizing uncertainty in both the reasoning about stream response and the quality of information used to drive the models. Prediction uncertainty can be quantified for any of the types of models described above; however, some types are more amenable to uncertainty analysis than others. For example, performing a Monte Carlo analysis of a coupled hydrologic-hydraulic model is a very demanding task. A simple sensitivity analysis of high, medium, and low values of plausible model parameters is much more tractable and still provides an improved understanding of the potential range of system responses. Such information can be subsequently integrated with other model outputs and expert judgment into a probabilistic framework. For example, Bayesian probability network approaches can accommodate a mix of inputs from mechanistic and statistical models, and expert judgment to quantify the probability of categorical states of stream response. Such networks also provide an explicit quantification of uncertainty, and lend themselves to continual updating and refinement as information and knowledge increase over time. As such, they

have many attractive features for hydromodification management, and are increasingly used in environmental modeling in support of water quality (Reckhow, 1999a,b) and stream-restoration decision-making (Stewart-Koster *et al.*, 2010).

2.3 Summary of Modeling Tools

At present, there is no definitive inventory and evaluation of hydromodification modeling tools in terms of the specific management questions the models address, relationships between models, and data requirements. Moreover, there are no formal guidelines for helping managers review and evaluate the appropriateness of modeling-based hydromodification analyses. With this goal in mind, Table 3 was developed to provide a tentative summary of the models that are currently considered most relevant to hydromodification management. It is important to note that decisions regarding which models to apply should be made based on a consideration of the questions being asked, the level of certainty required in the output, and ability to compile or collect necessary input data. In addition, the complexity and condition of the watershed of interest should be considered when selecting modeling tools.

Table 3. Summary of the models that are currently considered most relevant to hydromodification management.

Tools / Models	Example(s)	Type	Question(s) Addressed	Scale	Relation to Other Tools	Data Requirements	Relative Uncertainty	Key Considerations / Questions in Appropriate Use ⁹
Descriptive (D) Tools								
Rapid riparian/wetland assessments	CRAM	D	Level of wetland / riparian function?	reach to segment	Complements geomorphic assessment tools.	Field visit, readily available GIS and desktop data.	Low - Moderate	Were protocols properly followed?
Rapid channel susceptibility assessments	Bledsoe <i>et al.</i> , 2010, 2012	D	Relative channel susceptibility to hydromodification High, Medium, or Low?	reach to segment	Complements riparian assessment tools, vertical and lateral rating point to additional modeling tools, suggests in a coarse sense the level of mitigation that may be required.	Field visit, readily available GIS and desktop data.	Low - Moderate	Were protocols properly followed? For relative comparisons of susceptibility.
Geomorphic Landscape Units	Booth <i>et al.</i> , 2011	D	Where will development most affect runoff processes? Where are key sources of coarse sediment supply to stream channels? Where are priority areas for restricting development to maintain watershed processes? Where might "over-control" be necessary to mitigation reductions in sediment supply?	watershed - region	Complements channel stability assessments, land use planning.	Readily available GIS data.	Low - Moderate	Were protocols properly followed? For relative comparisons of potential sediment delivery.
Channel Evolution Model	Schumm <i>et al.</i> , 1984; Hawley <i>et al.</i> , 2012	D	What is the sequence of incision and/or braiding that can be expected over decades in disturbed channels? What geomorphic thresholds are most relevant to understanding channel response? How can unstable channels be classified for targeting rehabilitation measures?	reach to watershed	Identifies geomorphic thresholds quantified by braiding/incision predictors, highlights key processes that models of channel response may need to account for.	Field visit, expertise in fluvial geomorphology.	Low - Moderate	Are the predictions of other channel response models consistent with this framework, which processes / thresholds in the CEM are not accounted for in a modeling analysis?

Tools / Models	Example(s)	Type	Question(s) Addressed	Scale	Relation to Other Tools	Data Requirements	Relative Uncertainty	Key Considerations / Questions in Appropriate Use ⁸
Mechanistic (M) / Empirical-Statistical (E/S)								
Rainfall-runoff models	HSPF, SWMM, HEC-HMS	M	What are the estimated streamflows at an ungauged site? How will different types of land use change affect streamflow? How will peak flows change (single event modeling)? How will the long-term streamflow regime change in terms of magnitude, frequency, duration, flashiness, etc. (continuous modeling)?	watershed	Provide inputs in hydraulic models, shear stress and effective discharge calculators, SIAM, mobile boundary models. Continuous simulation outputs necessary to create flow-duration curves and to estimate important metrics like erosion potential for probabilistic models.	Several watershed GIS layers (e.g., precipitation, land cover, soils), streamflow data needed for calibration - long-term records of precipitation, land use change, calibration data required for continuous simulation.	Low - High, depends on data availability, calibration and testing	Is there match in the spatial and temporal scales and vintage of input data, are infiltration parameters consistent with standardized values for the study region, were 15-min data generated for flashy streams, was the model calibrated and validated?
Regional streamflow regressions	Hawley and Bledsoe, 2011	E/S	What are estimates of streamflow metrics at ungauged sites? How will urbanization affect streamflow at this ungauged site? How will peak flows and flow durations change in response to urbanization?	watershed	Complement rainfall-runoff models by providing an additional estimate of flow characteristics that is relatively straightforward to estimate. Can be used as a check of more detailed hydrology models.	Watershed GIS layers.	Moderate if not extrapolated beyond calibration data	Are the regressions applied within the range of conditions used to develop the model?
Hydraulic models	HEC-RAS	M, E/S	What are the hydraulic characteristics (e.g., shear stress, stream power) in a stream at a given discharge (or over some hydrograph)?	watershed to reach	Provides relationships between discharge and hydraulic variables like depth, slope, shear stress and stream power that are required inputs for any model that performs sediment-transport calculations.	Channel and structure geometry, flow resistance values, boundary conditions, and other parameters.	Low - High, depends on data availability, calibration and testing	How accurate are the channel geometry data, flow resistance parameters? Are structures and boundary conditions correctly specified?

Tools / Models	Example(s)	Type	Question(s) Addressed	Scale	Relation to Other Tools	Data Requirements	Relative Uncertainty	Key Considerations / Questions in Appropriate Use ^s
Mechanistic (M) / Empirical-Statistical (E/S) (Continued)								
Erosion models	WEPP (Water Erosion Prediction Project), SWAT (Soil and Water Assessment Tool)	M, E/S	How will hillslope erosion and watershed sediment delivery change in response to a change in land use or natural disturbance?	site - watershed	Provides an estimate of sediment delivery that can be used in sediment budgets and as a boundary condition in channel response models including mobile boundary models.	Several watershed GIS layers (e.g., precipitation, land cover, soils), sediment-delivery data needed for calibration – long-term records of precipitation, land use change, sediment data for calibration required for continuous simulation.	Very high	Difficult to obtain order of magnitude accuracy. Unreliable for most hydromodification applications except for relative comparisons of potential sediment delivery.
Gross erosion models	RUSLE2 (Revised Universal Soil Loss Equation)	E/S	How will gross erosion change in response to a change in land use or natural disturbance?	site - region	Provides an estimate of sediment delivery that can be used in sediment budgets and in models of relative channel response such as regime diagrams.	Readily available GIS data and table values needed. Some hydrologic data may be needed depending on model selection. Erosion data needed for testing.	High	Most accurate at annual time scales in relative comparisons of gross erosion. Must also account for gullies, sediment delivery.
Braiding / incision thresholds	Hawley <i>et al.</i> , 2012	E/S	Is this stream currently near a threshold of abrupt change in terms of accelerated widening or downcutting and bank failures?	reach to segment	Can be embedded in susceptibility screening tools, quantitative channel evolution models, and regime diagrams. Choice of incision vs. braiding discriminator requires understanding of channel evolution and boundary conditions.	Geomorphic and hydraulic characteristics – channel slope, discharge(s), grain size, stream power.	Moderate if not extrapolated beyond calibration data	Applied within range of applicability with consideration of lateral vs. vertical susceptibility.

Tools / Models	Example(s)	Type	Question(s) Addressed	Scale	Relation to Other Tools	Data Requirements	Relative Uncertainty	Key Considerations / Questions in Appropriate Use ⁹
Mechanistic (M) / Empirical-Statistical (E/S) (Continued)								
Regression-based channel enlargement models	Hawley and Bledsoe, In Review	E/S	How much might the cross-sectional area of a channel increase in response to an increase in watershed impervious area, a peak discharge, or cumulative erosion potential?	reach to segment	Provide a prediction of channel response that can be used in probabilistic modeling, provide a second line of evidence on relative channel response along with regime diagrams.	Watershed, geomorphic and hydraulic characteristics – channel slope, discharge(s), grain size, stream power, cumulative erosion potential.	Moderate if not extrapolated beyond calibration data	Applied within range of applicability, supported with other lines of evidence? Erosion potential-based models more physically-based than impervious-based models.
Regime diagrams	Chang, 1988; Parker, 1990; Haines, In Preparation	M, E/S	What is the equilibrium slope, width, and depth of a channel given a dominant discharge and inflowing sediment load? If channel-forming discharge and inflowing sediment load are altered, what is the new equilibrium channel slope, width, and/or depth in absolute terms or relative to a current equilibrium condition?	reach to segment	Provide a second line of evidence on relative channel response along with empirical enlargement models, and assessing relative sensitivity to changes in water and sediment delivery.	Channel-forming discharge, inflowing sediment concentration / load, boundary conditions including grain size, flow resistance.	Moderate to High depending on regional calibration	Typically provide maximum response of one channel dimension while other dimensions are not allowed to mutually adjust, brackets maximum response in a relative senses. Applied within range of applicability? Channel-forming discharge is poorly defined in many instances – regime diagrams may not be appropriate in such situations.
Effective discharge calculators	GeoTools	M, E/S	What range(s) of streamflow transport have the most capacity to transport sediment and influence channel form over periods of years to decades? What is the change in cumulative erosion potential associated with a change in the continuous series of streamflows? What is the time-integrated capacity to transport sediment relative to the capacity of an upstream supply reach?	reach to segment	Can help identify channel-forming discharge required by many channel response predictors (e.g., stable channel design calculators). Integrate continuous flow simulations from rainfall-runoff models, hydraulic model outputs, sediment-transport calculations to provide outputs like erosion potential that often form the basis of probabilistic models (e.g., logistic	Continuous streamflow data (15-min preferred for small watersheds in southern California), channel hydraulic geometry, grain sizes.	Moderate if not extrapolated beyond calibration data	Input flow series should be at least 10 and preferably 20 to 30 yrs of 15-min data. USACE (Biedenharn <i>et al.</i> , 2000) provide standard procedures for bin selection and other decisions. Was appropriate sediment-transport relationship used (bedload vs. total load, range of calibration)? Were channel boundary materials accurately defined?

Tools / Models	Example(s)	Type	Question(s) Addressed	Scale	Relation to Other Tools	Data Requirements	Relative Uncertainty	Key Considerations / Questions in Appropriate Use ⁹
Mechanistic (M) / Empirical-Statistical (E/S) (Continued)					and quantile regression, neural networks, Bayesian networks) of channel response.			
Sediment-transport / shear stress calculators	GeoTools, HEC-RAS, BAGS (Bedload Assessment for Gravel-bed Streams), San Diego tool	M, E/S	What is the estimated sediment-transport capacity of a stream at some discharge(s) of interest?	reach to segment	Provide an independent check on sediment-transport calculations performed by other software packages.	Channel hydraulic geometry, grain sizes, bed slope (uniform flow) or energy slope (varied flow).	Moderate to High depending on selection of appropriate relationship for local conditions	Was appropriate sediment-transport relationship used (bedload vs. total load, range of calibration)? Were channel boundary materials accurately defined? Were shear stresses or other hydraulic inputs generated using appropriate methods (e.g., see HEC-RAS above)? If single-event discharges are used, how are the full spectrum of transport events accounted for?
Stable channel design calculators	HEC-RAS, SAM, iSURF	M, E/S	What is the equilibrium slope, width, and depth of a channel given a dominant discharge and inflowing sediment load (or upstream supply reach characteristics)? If channel-forming discharge and inflowing sediment load are altered, what is the new equilibrium channel slope, width, and/or depth in absolute terms or relative to a current equilibrium condition?	reach to segment	Another way of expressing a regime diagram and assessing relative sensitivity to changes in water and sediment delivery. Facilitates examination of possible mutual adjustments in width, depth, and slope.	Channel-forming discharge, inflowing sediment concentration / load, boundary conditions including grain size, flow resistance.	Moderate to High depending on selection of appropriate relationship for local conditions	Was appropriate sediment-transport relationship used (bedload vs. total load, range of calibration)? Were channel boundary materials accurately defined? Were hydraulic geometry relationships or other hydraulic inputs generated using appropriate methods (e.g., see HEC-RAS above). If single-event discharges are used, how are the full spectrum of transport events accounted for? Channel-forming discharge is poorly defined in many instances - may not be appropriate in such situations.

Tools / Models	Example(s)	Type	Question(s) Addressed	Scale	Relation to Other Tools	Data Requirements	Relative Uncertainty	Key Considerations / Questions in Appropriate Use ^s
Mechanistic (M) / Empirical-Statistical (E/S) (Continued)								
Bank stability charts – regression of regional field data	Bledsoe <i>et al.</i> , 2012	E/S	Does this stream reach have banks that are close to a threshold of failure given its height and angle?	reach to segment	Can be embedded in susceptibility screening tools, quantitative channel evolution models, and regime diagrams. A much simplified empirical version of highly-detailed, mechanistic approaches like Bank Stability and Toe Erosion Model (BSTEM).	Field visit, bank height/angle, expertise in fluvial geomorphology.	Moderate to High depending on selection of appropriate relationship for local conditions	Requires consistency and expertise in fluvial geomorphology for adequate accuracy. Applied within range of applicability with consideration of lateral vs. vertical susceptibility.
Sediment budgeting tools	HEC-RAS - SIAM, Reid and Dunne, 1996		Given knowledge of streamflows and inflowing sediment loads, how do annualized sediment reach transport capacities compare to supplies? What are the locations of reaches of overall sediment surplus or deficit?		Can provide a network perspective on sediment imbalances that segment-scale approaches and mobile boundary models cannot. Does not translate changes into channel morphologic change like regime diagrams, stable channel design calculators and mobile boundary models.	Channel and structure geometry, flow resistance values, boundary conditions, and other parameters, flow-duration curves, sediment-supply data – source type (gully, surface, bank, U/S, and other), rate (tons/yr) and gradation.	High	Very difficult to define boundary conditions / inflowing sediment loads in southern California.
Bank stability / toe erosion models	USDA – BSTEM	M, E/S	How stable is this bank given its profile, stratigraphy, root reinforcement, drainage, scour, etc.?	sub-reach	Provides site-specific, physically-rigorous basis for predicting bank failures but more data and resource intensive than simplified field assessments.	Extensive parameterization required, e.g., geometric data, geotechnical properties, plant root properties, etc.	Moderate to High depending on availability of numerous input parameters	Meeting extensive input data requirements will rarely be feasible for hydromodification management.

Tools / Models	Example(s)	Type	Question(s) Addressed	Scale	Relation to Other Tools	Data Requirements	Relative Uncertainty	Key Considerations / Questions in Appropriate Use ⁵
Mechanistic (M) / Empirical-Statistical (E/S) (Continued)								
Mobile boundary models	HEC-RAS, HEC-6T, CONCEPTS, FLUVIAL12	M, E/S	What degree of aggradation, degradation, and change in channel form is expected along this stream reach?	reach to segment	Provide greatest resolution in morphologic change at the expense of complexity and difficult parameterization.	Extensive parameterization required, e.g., geometric data, sediment gradation and channel boundary conditions, flow resistance, inflowing sediment loads, etc.	Very High	Generally not applicable to southern California streams given high prediction uncertainty due to flows near critical, split flow conditions, and lack of fidelity to complex widening, bank failure, and bed-armoring processes.
Probabilistic (P) Models								
Logistic regression models of channel instability and enlargement	Palhegyi and Bicknell, 2004; Hawley and Bledsoe, In Review	P	What is the probability of channel instability (or some other undesirable state) given some change in streamflow / sediment-transport characteristics (e.g., erosion potential)? What is the probability of some level of channel enlargement given some increase in imperviousness or erosion potential without mitigation? What is the uncertainty in a prediction of instability, enlargement of some other impact?	reach to segment	Integrates several of the models above (hydrologic, hydraulic, sediment transport) to predict likelihood of channel response based on process-based metrics that control erosion potential. More familiar and easier to understand than neural networks or Bayesian approaches.	Metric(s) of hydromodification impact and context (e.g., erosion potential) typically based on combination of channel geometry, continuous flow series, and channel boundary conditions (bed and bank materials).	Explicitly known, typically moderate with appropriate data	Perhaps most appropriate balance of physical detail and simplicity in application currently available. Several of the models described above supply input information; therefore, all the considerations and questions associated with those models apply to these integrative tools as well. Standard statistical diagnostics should be performed.

Tools / Models	Example(s)	Type	Question(s) Addressed	Scale	Relation to Other Tools	Data Requirements	Relative Uncertainty	Key Considerations / Questions in Appropriate Use [§]
Probabilistic (P) Models (Continued)								
Neural network models of channel enlargement	Sengupta <i>et al.</i> , In Review	P	What is the probability of some level of channel enlargement given some increase in imperviousness or erosion potential without mitigation? What is the uncertainty in a prediction of instability, enlargement of some other impact?	reach to segment	Integrates several of the models above (hydrologic, hydraulic, sediment transport) to predict likelihood of channel response based on process-based metrics that control erosion potential. Can handle many types of input data and complex interactions and non-linear responses.	Metric(s) of hydromodification impact and context (e.g., erosion potential) typically based on combination of channel geometry, continuous flow series, and channel boundary conditions (bed and bank materials).	Explicitly known, typically moderate with appropriate data	Appropriate balance of physical detail and simplicity in application currently available. Several of the models described above supply input information; therefore, all the considerations and questions associated with those models apply to these integrative tools as well. Somewhat more difficult to interpret than more familiar models like logistic regression.
Bayesian networks	Borsuk <i>et al.</i> , 2004; Stewart-Koster <i>et al.</i> , 2010; Shultz <i>et al.</i> , 2011	P	What is the probability of channel instability (or some other undesirable state) given some change in streamflow / sediment-transport characteristics (e.g., erosion potential)? What is the probability of some level of channel enlargement given some increase in imperviousness or erosion potential without mitigation? What is the uncertainty in a prediction of instability, enlargement of some other impact?	reach to segment	Integrates several of the models above (hydrologic, hydraulic, sediment transport) to predict likelihood of channel response based on process-based metrics that control erosion potential. Combines many types of data and models along with expert judgment into a unified probabilistic framework. Prediction uncertainty is clearly expressed in outputs.	Metric(s) of hydromodification impact (e.g., erosion potential) typically based on combination of channel geometry, continuous flow series, and channel boundary conditions (bed and bank materials), can readily incorporate data from mechanistic models, categorical data, and expert judgment.	Explicitly known, typically moderate with appropriate data	Appropriate balance of physical detail and simplicity in application currently available. Several of the models described above supply input information; therefore, all the considerations and questions associated with those models apply to these integrative tools as well. Somewhat more difficult to interpret than more familiar models like logistic regression. Prior probabilities should be non-informative without clearly documented evidence from literature or formal elicitation process.

[§] Key considerations that control precision and accuracy for all models: 1) model structure, detail, resolution, and boundaries; and 2) calibration, validation, and extrapolation.

Managers must also attempt to ensure that the level of analysis of potential hydromodification impacts is commensurate with the risks associated with a particular decision. Rapid geomorphic assessments and screening tools like the one developed by SCCWRP and CSU assess the relative susceptibility of channels to hydromodification. Susceptibility is described in terms of lateral change (bank erosion, widening, shift to braiding) and vertical change (incision and enlargement) based on several physically-based risk factors. It follows that the risk factors leading to a particular susceptibility rating can inform the selection of additional models that can be used to perform a more rigorous assessment of susceptibility. Table 4 illustrates some hypothetical relationships between different combinations of lateral and vertical susceptibility ratings and models that are relevant to more in-depth modeling and analysis of potential channel response to hydromodification. It is important to recognize that the same susceptibility rating can result from different risk factors. For example, one channel may be rated high for lateral susceptibility due to proximity to a braiding threshold and another channel may be rated high due to unconsolidated materials in the bank toe. Thus, the screening ratings do not map directly to a specific set of models that are appropriate for a more in-depth analysis. Instead, it is recommended that managers focus on the risk factors (e.g., proximity to critical bank height and angle) that result in a particular rating and to choose supporting models that provide more resolution in understanding the processes associated with those specific risk factors. It is important to note that we are not including single-event hydrologic modeling in Table 4 because: 1) single-event modeling does not provide critical information on how altered flow frequencies and durations affect cumulative sediment transport capacity, and 2) the highly significant influence of time-integrated erosion potential in the statistical models focused on channel enlargement and instability as described above suggests that single event modeling does not produce sufficiently reliable predictions of future conditions.

Table 4. Matrix illustrating combinations of geomorphic modeling tools for each combination of V and L ratings.

Vertical (V) Rating	H	1,2,4,6,7,8	1,2, ,4,5,6,7,8,9	1,2,3,4,5,6,7,8,9,10,11
	M	1,2,4,6,7,8	1,2, ,4,5,6,7,8	1,2,4,5,6,7,8,9,10

2.4 Combining Tools for Hydromodification Management

This section provides a discussion of four example “suites of tools” that can be used to perform predictive scientific assessments and address specific questions related to hydromodification assessment and management. The suites are changeable mixes of mechanistic models, statistical analyses, and expert scientific judgment that incorporates a number of the tools discussed above, combined in various ways. For example, some suites apply a series of cascading models, in which the output from one is used as input to the next; other suites apply a number of models in parallel to develop an assessment based on the weight of evidence. The suites of tools discussed below are used to perform a baseline stability assessment, a channel-forming discharge analysis, an erosion potential analysis, and a sediment-transport analysis. Most of these standard tools (with the exception of the erosion potential suite) have been widely employed in a variety of stream management activities for decades, and are considered essential components of the broader fluvial geomorphology toolbox. This is far from a comprehensive list of tools, as there are many other important tools (focused on both geomorphic and biologic endpoints) relevant to hydromodification management (Kondolf and Piégay, 2003; Poff *et al.*, 2010); however, the purpose of this section is to briefly illustrate how several standard tools can be integrated to answer key questions about stream responses and to provide a stronger technical basis for hydromodification management.

Application of these tools provides basic geomorphic data and knowledge that are typically needed to manage a stream for some desired future state in a watershed with changing land uses. This critical information comes at a cost—the tools require substantially more time and effort to apply than has been the norm in hydromodification management because they involve examining streams within their watershed context with a deeper level of geomorphic analysis. Stormwater management programs typically have made the “practical” assumptions that stream reaches can be managed in isolation from the larger systems of which they are a part, and that effective management prescriptions can be formulated with little or no substantive geomorphic analysis. These assumptions are in direct conflict with current understanding in fluvial geomorphology and stream ecology, which indicates that protection of stream integrity is often predicated upon careful assessments of geologic and historical context, performing detailed hydraulic and sedimentation analyses where appropriate, and developing basic understanding of streamflow-ecology linkages. If hydromodification management policies are to have a reasonable chance of actually achieving their aims, then it will most likely be necessary to reject these simplifying assumptions and instead rely on approaches rooted in current scientific understanding of stream systems.

“This critical information comes at a cost—the tools require substantially more time and effort to apply than has been the norm in hydromodification management because they involve examining streams within their watershed context with a deeper level of geomorphic analysis.”

The suites of tools described below go beyond screening-level assessments that are designed, in part, to identify which streams lend themselves to relatively-straightforward management prescriptions vs. the streams that do not. For streams that do not lend themselves to generic management prescriptions, the

level of analysis performed with these tools should increase with the level of risk and geomorphic / biologic susceptibility of the streams. This does not mean that every stream will require in-depth analysis by local permitting agencies. It is not possible to carry out sufficient geomorphic analyses with the tools illustrated below on a permit-by-permit basis, and local governments may lack the resources and/or technical capacity to effectively apply these tools. Instead, the vital information provided by these tools will need to be obtained through proactive regional studies that involve watershed-scale baseline assessments followed by progressively more in-depth analyses as necessary to provide local governments with a sound basis for effective project-by-project decision-making within a broader watershed management framework.

1. **Baseline Stability Assessment.** This suite of tools is designed to answer the following key questions:

- What is the trajectory of the stream's form over time?
- How has the channel form responded to changes in water and sediment supply over the years?
- Is the channel close to a geomorphic threshold that could result in rapid, significant change in response to only minor flow alteration?
- How can past channel responses provide insight into potential responses to future watershed change, and so aid in prediction of future hydromodification-induced changes?
- What level of subsequent geomorphic analysis is appropriate given the complexity of the situation and the susceptibility of the streams of interest?

The goals of a baseline stability assessment are to:

- Document the historical trends of the system;
- Establish the present stability status of the system and identify the dominant processes and features within the system;
- Provide the foundation for projecting future trends with and without proposed project features;
- Provide critical data for calibration and proper interpretation of models; and
- Provide a rational basis for identification and design of effective alternatives to meet project goals.

The key tools that comprise this suite include:

- GIS mapping of topography, soils, geology, land use / land cover across the contributing watershed (e.g., Thorne, 2002);
- Analysis of hydro-climatic data, e.g., streamflow gage records, changes in stage-discharge relationships over time (e.g., Thorne, 2002);
- Analysis of aerial photographs and historical data (e.g., Thorne, 2002);
- Field reconnaissance (e.g., Thorne, 1998);
- Qualitative response (e.g., Lane, 1955b; Schumm, 1969; and Henderson, 1966 relations)
- Classification systems (e.g., Thorne (1997); Schumm (1977); and CEM developed for southern California by Hawley *et al.*, 2012);
- Relationships between sediment transport and hydraulic variables;
- Regional hydraulic geometry (e.g., Hawley, 2009) and Haines, In Preparation);

- Regional planform and stability predictors (e.g., Hawley *et al.*, 2012; Bledsoe *et al.*, 2012; and Dust and Wohl, 2010);
- Bank stability analysis (e.g., BSTEM <http://www.ars.usda.gov/Research/docs.htm?docid=5044>, Hawley, 2009); Bledsoe *et al.*, In Press; Osman and Thorne, 1988; and Thorne *et al.*, 1998);
- Sediment budgets (Booth *et al.*, 2010; Reid and Dunne, 1996); and
- Fluvial audit (Thorne, 2002) – a comprehensive framework for performing baseline assessments).

A baseline assessment is completed by integrating information from all the available data sources and analytical tools. Analysis with each of the individual tools may yield a verdict of aggradation, degradation, or dynamic equilibrium with respect to the channel bed, and stable or unstable with respect to the banks. The individual assessments can produce contradictory results. In this case, one should assign a level of confidence to the various components based on the reliability and availability of the data, and the analyst's own experience level. As is often the case in the management of fluvial systems, there is no "cookbook" answer, and we must always incorporate sound judgment.

2. **Channel-forming discharge suite of tools.** This suite of tools is designed to answer the following key questions:

- What ranges of discharges are most influential in controlling channel form and processes over decadal time scales?
- What channel-forming discharges should be used in sediment-transport analyses to identify sediment-transport capacity, equilibrium slope and geometry, etc.?

The tools that comprise this suite include the following:

- Effective discharge computations (e.g., Soar and Thorne, 2001); Biedenharn *et al.*, 2000; GeoTools – Bledsoe *et al.*, 2007) – an effective discharge analysis directly quantifies the range of discharges that transport the largest portion of the annual sediment yield over a period of many years;
- Field identification of high water elevations, depositional surfaces, and "bankfull" features;
- Flood frequency analysis; and
- Un-gaged site analysis (e.g., USGS StreamStats, <http://water.usgs.gov/osw/streamstats/california.html>); Hawley and Bledsoe, 2011, regional flow-duration curve extrapolation – Biedenharn *et al.*, 2000).

This suite incorporates a number of parallel analyses that can be used to establish likely upper and lower bounds to the range of influential discharges, and that can be assessed through a weight-of-evidence evaluation. Figure 17 is an example output from the channel-forming discharge suite of tools.

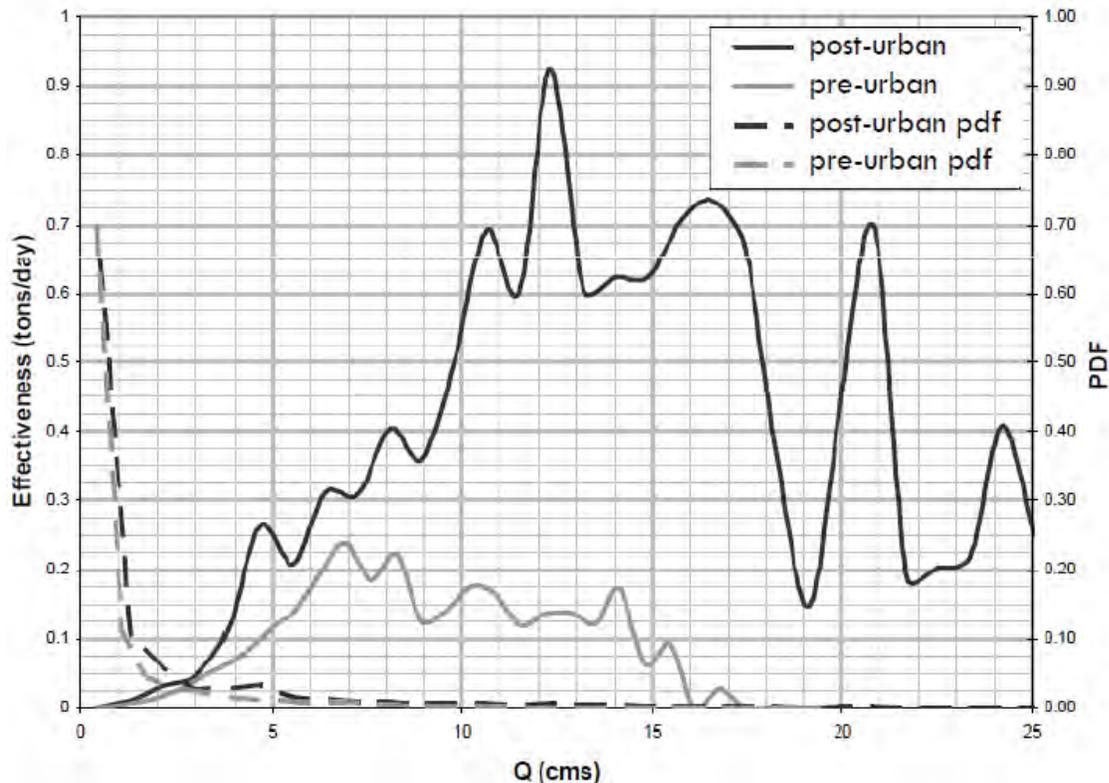

Figure 17. Flow effectiveness curves for continuous series of pre-urban and post-urban discharges (Biedenharn *et al.*, 2000; Bledsoe *et al.*, 2007). Cumulative sediment yield is approximated by the area under the respective curves. If the stream bed is the most erodible channel boundary, the ratio of areas under these curves would be the erosion potential metric described below in the next suite of tools.

3. **Erosion potential suite of tools.** This suite of tools is designed to answer the following key questions:
- How do proposed land use changes or channel alteration affect the capacity of a channel to transport the *most erodible material in its boundary* over a period of many years (erosion potential – E_p)?
 - Do proposed mitigation approaches match the pre- vs. post-development erosion potential over the full spectrum of erosive flows?
 - Do past changes in erosion potential correspond to different states of channel stability and degradation in this region?
 - Does a proposed change in streamflow make it more likely that a channel will enter an alternative / degraded state?

The underlying premise of the erosion potential approach advances the concept of flow-duration control (discussed in Chapters 2 and 3 of Technical Report #667 *Hydromodification Assessment and Management in California* (Stein *et al.*, 2012)) by addressing in-stream processes related to sediment transport. An erosion potential calculation combines flow parameters with stream geometry to assess long-term (decadal) changes in the sediment-transport capacity. The cumulative distribution of shear

stress, specific stream power, and sediment-transport capacity across the entire range of relevant flows can be calculated and expressed using an erosion potential metric, E_p (e.g., Bledsoe, 2002). This erosion potential metric is a simple ratio of post- vs. pre-development sediment-transport capacity over a period of many years. The calculated capacity to transport sediment can be based on the channel bed material or the bank material, depending on which one is more erodible.

This E_p suite of tools has been applied in two primary ways:

1. At a project-level analysis, it has been applied to answer the first two questions above. A municipal stormwater permit may require a project design to achieve an erosion potential (E_p) value of 1.0. This means that a project must be designed so that the long-term erosion potential of the site's stormwater discharge is equal to the erosion potential of the pre-development condition. Item 3.1 below explains the process by which this analysis is conducted.
2. At a regional level, this suite of tools can be applied to answer the third and fourth questions above and to provide further guidance to project-level assessments. For example, practical engineering considerations generally require that a tolerance be permitted around a target design value. It is unlikely that a project design can match an E_p target of 1.0 across all conditions and through all stream reaches, due to variations in a multitude of contributing factors. The selection of an acceptable tolerance or variance from 1.0 is a management decision that should be informed by regional data presented in a risk-based format. Item 3.2 below explains how such a study has been conducted, using the Santa Clara Valley example from northern California.

2.4.1 *Project-level Analysis.*

As applied to the analysis of project impacts and mitigation design, the steps and associated tools that comprise this suite include the following (Figure 18):

- Perform continuous simulation of hydrology (e.g., SWMM, HEC-HMS, HSPF) for the project site, for both pre-project condition and post-project condition with the proposed mitigation design.
- Convert discharges and field surveys to hydraulic parameters (shear stress and specific stream power) – e.g., for uniform flow analysis use Manning's equation, GeoTools; for varied flow analysis use HEC-RAS.
- Convert hydraulic parameters into sediment-transport capacity – e.g., at-a-station hydraulic geometry, HEC-RAS, GeoTools, sediment-transport relationships (bedload and total load).
- Integrate E_p over time – e.g., GeoToolsCompare E_p values for pre-development and post-development to determine if the proposed mitigation design is adequate. Adjust stormwater controls as necessary to meet target E_p .

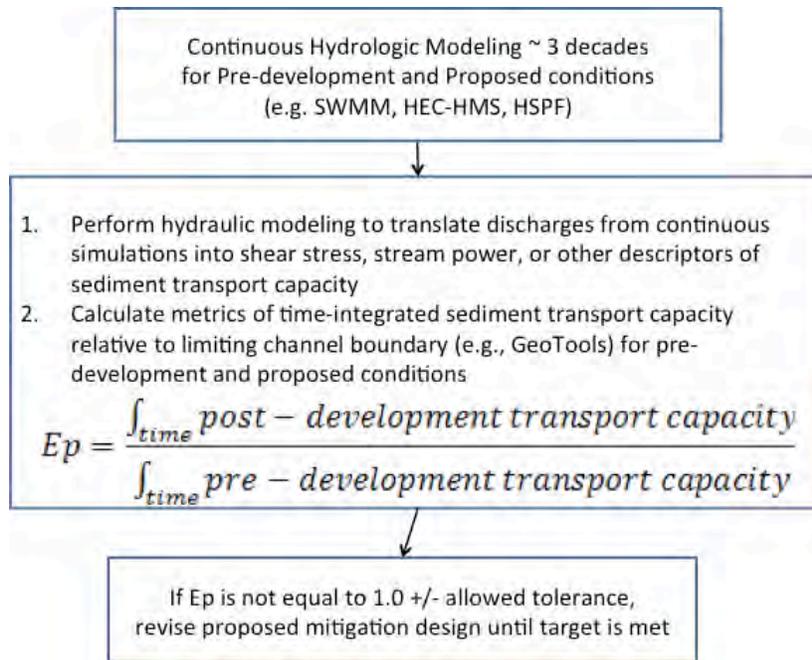

Figure 18. Steps involved in a project-level erosion potential analysis.

2.4.2 Risk-based Regional Analysis.

Risk-based modeling estimates the probability of stream geomorphic states. Decision-makers can then choose acceptable risk levels based on an explicit estimate of prediction error. The foundation of risk-based modeling in the context of hydromodification management is the integration of hydrologic and geomorphic data derived from the output of continuous hydrologic simulation models to generate metrics describing expected departures in the most important stream processes. These physical metrics are provided as inputs to probabilistic models that estimate the risk of streams shifting to some undesirable state. Because the decision endpoint is often categorical (e.g., stable, good habitat) the statistical tools of choice are often logistic regression, classification and regression trees (CART), and/or Bayesian probability networks.

The steps below are used to develop a risk-based framework (Figure 19) for assessing how hydromodification may impact streams within a region, and for understanding the relationships between E_p and the likelihood of channel instability. Both Figure 15 described above and the probabilistic approach that was used in the development of the Santa Clara Valley Urban Runoff Program Hydromodification Management Plan (<http://www.SCVURPPP.org>) demonstrate that a time-integrated index of erosion potential based on continuous hydrologic simulation and an assessment of stream power relative to the erodibility of channel boundary materials can be used to distinguish between channels of a particular regional type that are stable vs. degraded by hydromodification in urban watersheds. For example, as erosion potential increases from 0.7 to 1.5, the risk of channel instability (vertical axis) increases nonlinearly (Figure 15). The overall steps include:

- Perform project-level analysis as described above for existing developments throughout the study watersheds.
- Perform stream surveys throughout the study watersheds to characterize condition (i.e., stable, unstable).
- Create statistical relationships between E_p and different channel states – e.g., logistic regression in R, SAS, Statistica, Minitab, etc. Note that standard regression techniques are applied when the dependent variable and the explanatory variables are quantitative and continuous. To analyze a binary qualitative variable (e.g., 0 or 1, stable or unstable, healthy or degraded) as a function of a number of explanatory variables, alternative techniques must be used. The regression problem may be revised so that, rather than predicting a binary variable, the regression model predicts a continuous probability of the binary variable that stays within 0–1 bounds. One of the most common regression models that accomplishes this is the logit or logistic regression model (Menard, 1995; Christensen, 1997).

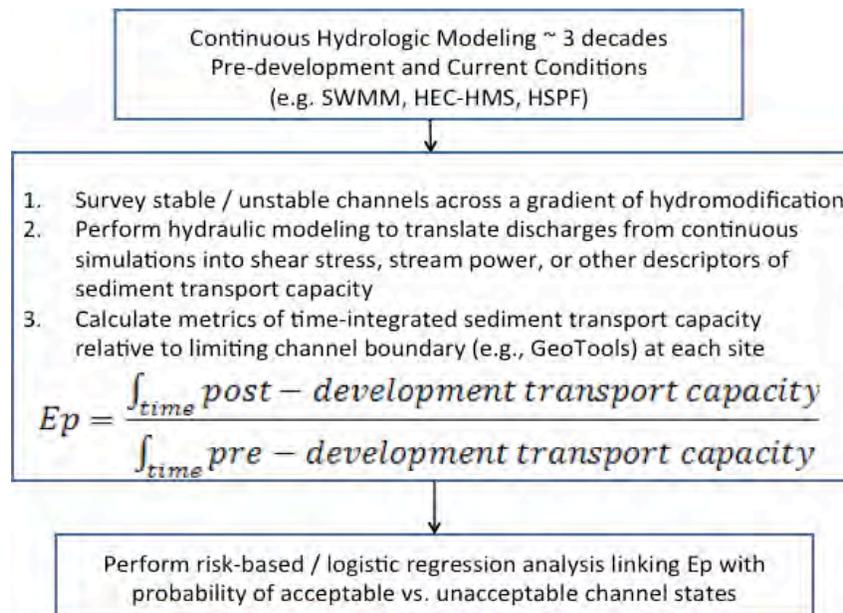

Figure 19. Steps involved in a risk-based erosion potential analysis.

The variables included in risk-based models of stream response are not limited to erosion potential. Additional multi-scale controls could be included. For example, simple categories of physical habitat condition and ecological integrity could be predicted by augmenting erosion potential metrics with descriptors of the condition of channel banks and riparian zones, geologic influences, floodplain connectedness, hydrologic metrics describing flashiness, proximity to known thresholds of planform change, and BMP types. Furthermore, although most of the emphasis to date has been on predicting geomorphic endpoints, the risk-based approach can be extended to the prediction of biological states in urban streams if the necessary data are available.

2.4.3 Strengths and Limitations

The erosion potential approach combines a sound physical basis with probabilistic outputs and requires a substantial modeling effort. Such an effort is necessary to adequately characterize the effects of hydromodification on the stability of streams that are not armored with very coarse material such as large cobbles and boulders. Although policies based on this approach should reduce impacts to channel morphology, they may still fail to protect stream functions and biota. Key simplifying assumptions and prediction uncertainty in the inputs (hydrologic modeling, assumptions of static channel geometry in developing long-term series of shear stresses or stream powers, critical assumptions of stationarity in sediment supply, etc.) have not been rigorously addressed. Its effectiveness also depends on careful stratification of streams in a region such that fundamentally-different stream types are not lumped together (e.g., labile sand channels vs. armored threshold channels with grade control) in developing general relationships for instability risk. Endpoints to date have been rather coarse, e.g., stable vs. unstable; as such, they do not provide a desirable level of resolution for envisioning future stream states. Nevertheless, the erosion potential approach is an important tool in the hydromodification management toolbox. It is recommended that this approach be refined to address sediment-supply changes and to provide more finely resolved endpoints for improved predictive capabilities and management utility.

2.4.4 Sediment-transport Analysis Suite of Tools

This suite of tools is designed to answer the following questions:

- Do I need to incorporate sediment-transport analysis in predicting channel response to hydromodification, i.e., what is the sensitivity of channel slope and geometry to inflowing sediment load?
- At what discharges are different fractions of bed material mobilized in a particular stream segment?
- What is inflowing sediment load to a stream segment, i.e., what is the water discharge $Q(t)$ and sediment-supply rate $Q_s(t)$, and grain size $D(t)$ delivered to the upstream end of the channel segment of interest?
- How will the available flow move the supplied sediment through the segment of interest?
- What is the new equilibrium slope given some change in streamflow, and how much incision would be necessary to achieve this new slope?
- What is the sediment-transport capacity of the segment of interest *relative to* the inflowing sediment load from *upstream* supply reaches?
- What is the sediment-transport capacity of the segment of interest *relative to* the capacity of *downstream* reaches?
- At the network scale, where are zones of low vs. high energy, aggradation vs. degradation potential, and coarse sediment constriction located?

The primary tools that comprise this suite include the following:

- Tools for estimating watershed sediment supply (Reid and Dunne, 1996), including the RUSLE (Renard *et al.*, 1997); <http://www.ars.usda.gov/Research/docs.htm?docid=5971> and WEPP (Laflen *et al.*, 1991); <http://www.ars.usda.gov/Research/docs.htm?docid=10621> models;
- Effective discharge analysis (see above);
- Incipient motion analysis (tractive force, e.g., ASCE, 2008; Brown and Caldwell, 2011; Buffington and Montgomery, 1997; and Lane, 1955a);
- Regime diagrams that provide relative and absolute predictions of channel dimensions and slope in response to altered discharges of water and sediment (this project)
- Sediment continuity analysis at single dominant discharge with an appropriate sediment-transport relation – e.g., HEC-RAS, Bedload Assessment for Gravel-bed Streams (BAGS – Pitlick *et al.*, 2009); GeoTools);
- Equilibrium slope / geometry analysis, e.g., HEC-RAS – Copeland *et al.* (2001) and iSURF – National Center for Earth-Surface Dynamics (NCED, 2011);
- Sensitivity to inflowing sediment load analysis, e.g., Copeland’s method in HEC-RAS and iSURF – NCED (2011);
- Sediment continuity analysis over the entire flow frequency distribution, e.g., Capacity-Supply Ratio of Soar and Thorne (2001), BAGS, GeoTools; and
- Network-scale sediment balance – Sediment Impact Analysis Methods (SIAM) module in HEC-RAS.

Figures 20 and 21 depict example outputs from an application of the sediment-transport suite of tools.

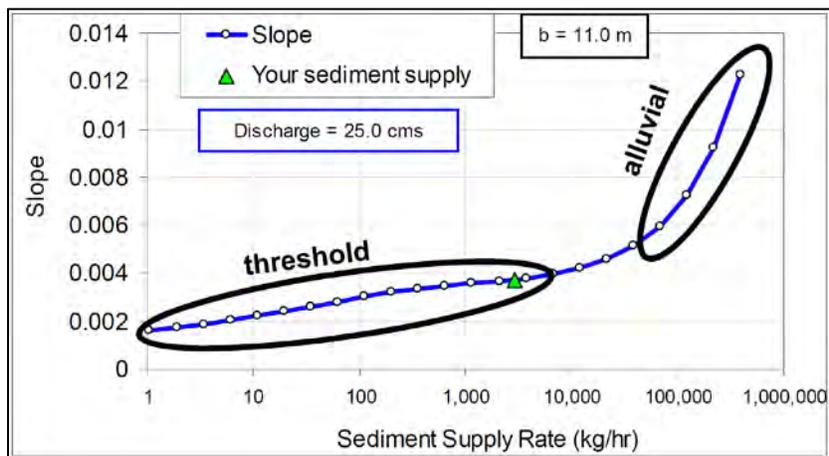

Figure 20. Sensitivity analysis of equilibrium channel slope to inflowing sediment load (from iSURF (NCED, 2011)). Slopes of alluvial channels with high sediment supply are much more sensitive than threshold channels with relatively low sediment supply. Channels with beds composed of sand and fine gravels are generally much more geomorphically sensitive to hydromodification than threshold channels in which coarse-bed sediments are primarily transported at relatively high flows. In the case of the green triangle, this analysis indicates that the slope of the channel in question is relatively insensitive to changes in inflowing sediment load compared to more labile alluvial channels that are adjusted to high sediment supplies.

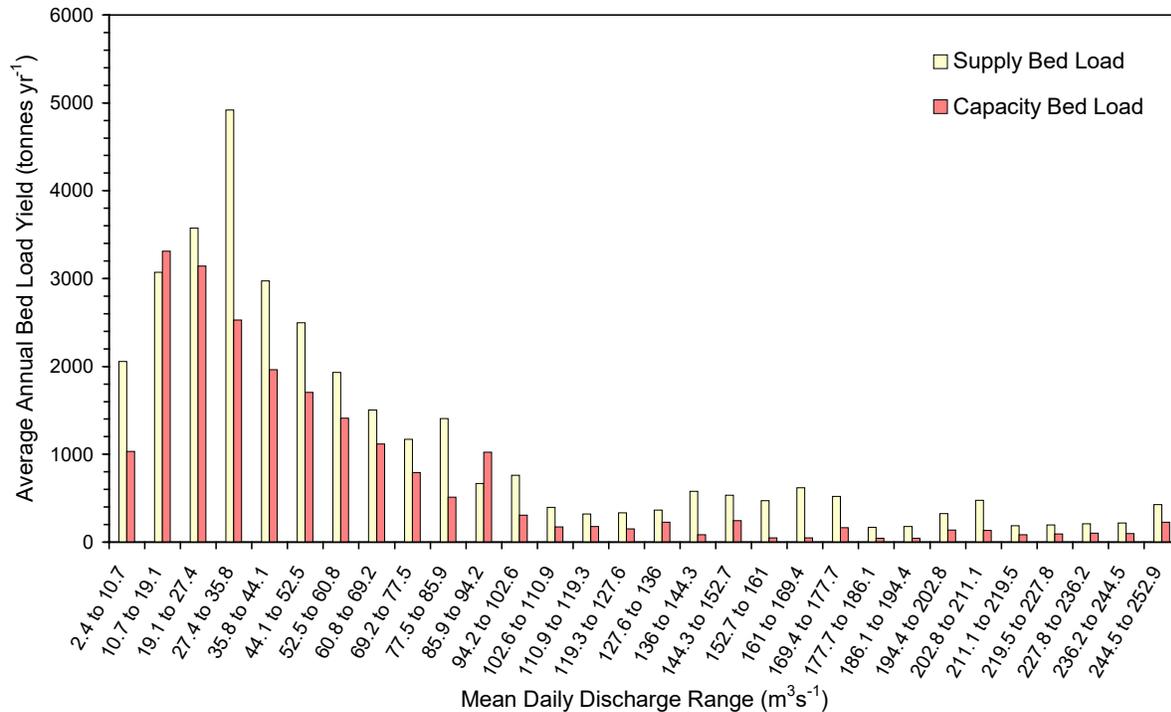

Figure 21. Analysis of sediment-transport capacity vs. inflowing sediment load over the full spectrum of stream discharges (capacity-supply ratio; Soar and Thorne (2001)). In this case, the time-integrated capacity to transport bedload is 64% of the supplied bedload and significant aggradation is expected.

2.4.5 Relationship to Management Framework

These suites of tools could be applied to establish project-specific requirements for hydromodification assessment and mitigation. In the example shown in the diagram below (Figure 22), results of the Baseline Assessment are used to assign risk levels for stream reaches, in conjunction with the proposed land use changes. Thus, the Baseline Assessment suite of tools is used in determining whether a detailed survey-level assessment and additional suites of tools are necessary for an adequate analysis. The need to apply additional suites of tools in formulating a management approach is commensurate with the level of risk and susceptibility of the stream. More complex and rigorous analysis with multiple suites of tools is necessary in predictive assessments for relatively susceptible stream types such as alluvial channels with sand beds.

Although a stream may have relatively low susceptibility for overall geomorphic change, it may nevertheless have ecological attributes that are highly susceptible to hydromodification. Thus, suites of tools (Figure 22) focused on both geomorphic and biological endpoints should be used to fully assess stream susceptibility to hydromodification. More work will be required to develop tools for prediction of biological response to flow alterations throughout California (see Poff *et al.*, 2010) and <http://conserveonline.org/workspaces/eloha>).

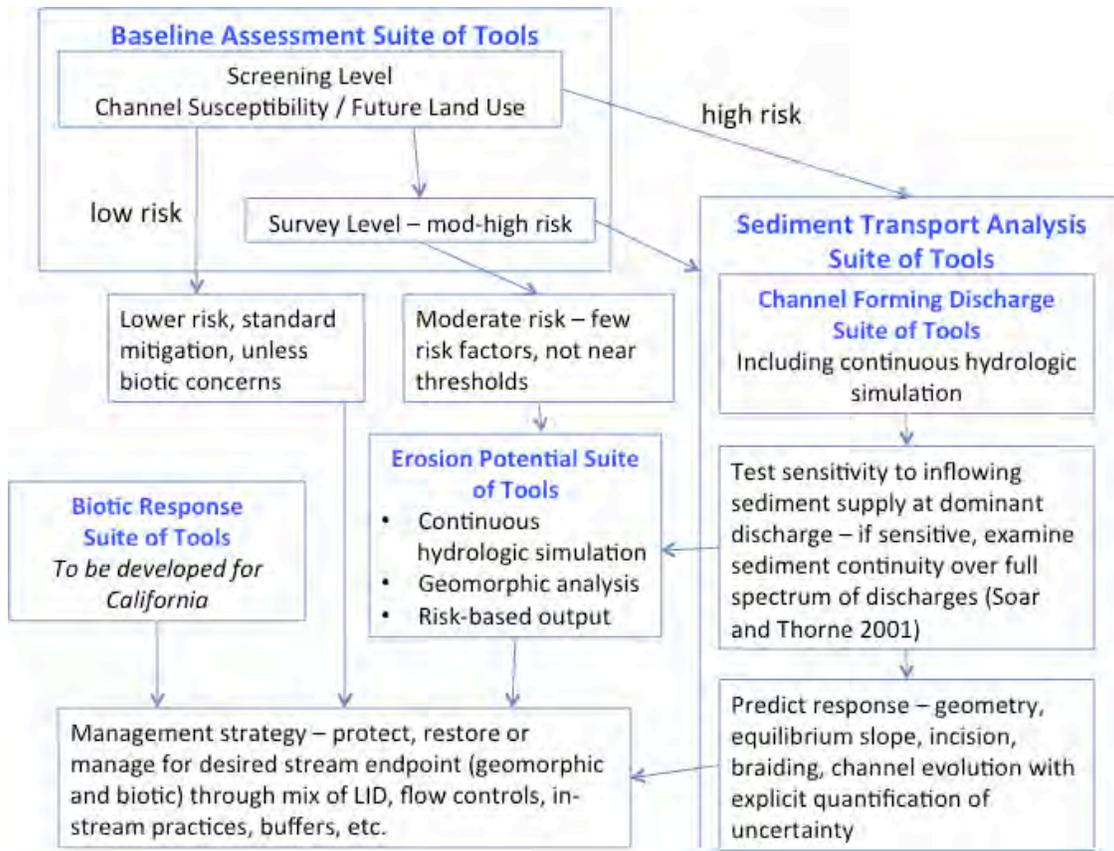

Figure 22. Conceptual diagram showing relationships among the four suites of existing tools and biotic response tools to be developed in the future. Additional analyses will be required for engineering design.

2.5 Available Tools Conclusions

This project has developed several new modeling tools to support hydromodification management in southern California, including hydrologic tools for prediction in ungauged basins, analytical regime diagrams, channel enlargement models based on regression and ANNs, and an updated version of the GeoTools package.

These tools, in combination with existing tools, have the potential to advance hydromodification management by:

- Providing a physical basis for making predictions of stream response to watershed development.
- Assessing alternative future states of streams under different management scenarios.
- Avoiding one-size-fits-all solutions through:
 - improved prediction of relative magnitude of potential channel change and proximity to response thresholds; and
 - tailoring mitigation strategies to streams with different levels of susceptibility.

Statistical models developed in this study indicate that channel enlargement is highly dependent on the ratio of post- to pre-urban sediment-transport capacity over cumulative duration simulations of 25 years (load ratio, a.k.a. erosion potential), which explained nearly 60% of the variance in channel response. Neural network models developed in this study indicated that estimated increases in Q_2 based on regional flood regression equations (Hawley and Bledsoe, 2011) consistently ranked as the most important predictor of channel enlargement despite the inclusion of a large pool of watershed and geomorphic descriptors at various spatial scales. Thus, the enlargement models point to the importance of balancing the post-development sediment transport to the pre-development setting over an entire range of flows rather than a single flow in order to reduce the risk of adverse channel responses to hydromodification.

We also evaluated the potential applicability of various movable bed and/or boundary models to predicting channel response to hydromodification in southern California. These tests indicated that mobile boundary hydraulic models are difficult to apply and have high prediction uncertainty due to flows near critical, split flow conditions, and lack of fidelity to complex widening, bank failure, and bed-armoring processes.

The tools developed in this project have a clear physical basis; however, their efficacy for predicting the effects of hydromodification has not been demonstrated. As such, there is a pressing need for monitoring data to test and improve models. There is also an ongoing need to better define predictive scientific assessments (changeable mixes of mechanistic models, statistical analyses, and expert scientific judgment) that are most appropriate for answering hydromodification management questions. The mechanistic models included in such assessments should account for hydraulic characteristics through physically-based metrics like load ratio / erosion potential, as opposed to arbitrary thresholds of discharge. By converting discharge values into hydraulic variables (common choices are shear stress or stream power per unit area of channel relative to bed sediment size), a “common currency” for managing erosion and associated effects can be established and applied across many streams in a region. Assessments of potential stream responses to management decisions should also account for the dominant watershed processes and features within the broader system that constrain future geomorphic potential (and although not emphasized in this study, ecological potential). This critical information comes at a cost—the tools require substantially more time and effort to apply than has been the norm in hydromodification management because they involve examining streams within their watershed context with a deeper level of geomorphic analysis.

Given the uncertainty associated with predicting hydromodification impacts, probabilistic models should be incorporated into analysis and design, particularly where resource values or potential consequences of impacts are high. Probabilistic modeling of urbanizing streams provides a more scientifically-defensible alternative to standardization of stormwater controls across all stream types, and can inform management decisions about acceptable levels of risk. Explicit consideration, quantification, and gradual reduction of model uncertainty will be necessary to advance hydromodification management. Thus, there is a need to develop probabilistic modeling approaches that can be updated and refined as knowledge increases over time. Such approaches must be amenable to categorical inputs and outputs, as well as combining data from a mix of sources including mechanistic hydrology models, statistical

models based on field surveys of stream characteristics, and expert judgment. Although valuable, deterministic representations (such as those derived from continuous simulation modeling) of processes and responses can mask uncertainties and be misleadingly precise unless prediction uncertainty is explicitly characterized. Ultimately, the focus of scientific study in support of decision-making should be on the decisions (or objectives) associated with the resource and not on building more-detailed models with the hope that they will provide the answers that elude us.

The uncertainty inherent to hydromodification modeling also underscores the need for carefully designed monitoring and adaptive management programs. Emphasis should be placed on building an empirical basis for these tools through effective monitoring.

3.0 DECISION-MAKING APPROACH

Managing effects of hydromodification is the culmination of all preceding analysis (Figure 23). It entails efforts to remedy existing/past impacts as well as prevent or minimize the potential for future impacts. Hydromodification results from a complex set of processes over long-periods of time; therefore, a suite of management approaches will often be necessary to address the effects. The ultimate management prescription should also account for existing and future constraints in the watershed that may limit the ability to apply certain approaches (e.g., existing development and channelization). As with all other sets of technical recommendations, the guidelines and recommendations provided below are intended to provide resources to guide location-specific decisions rather than prescriptive approaches to be universally applied in all situations.

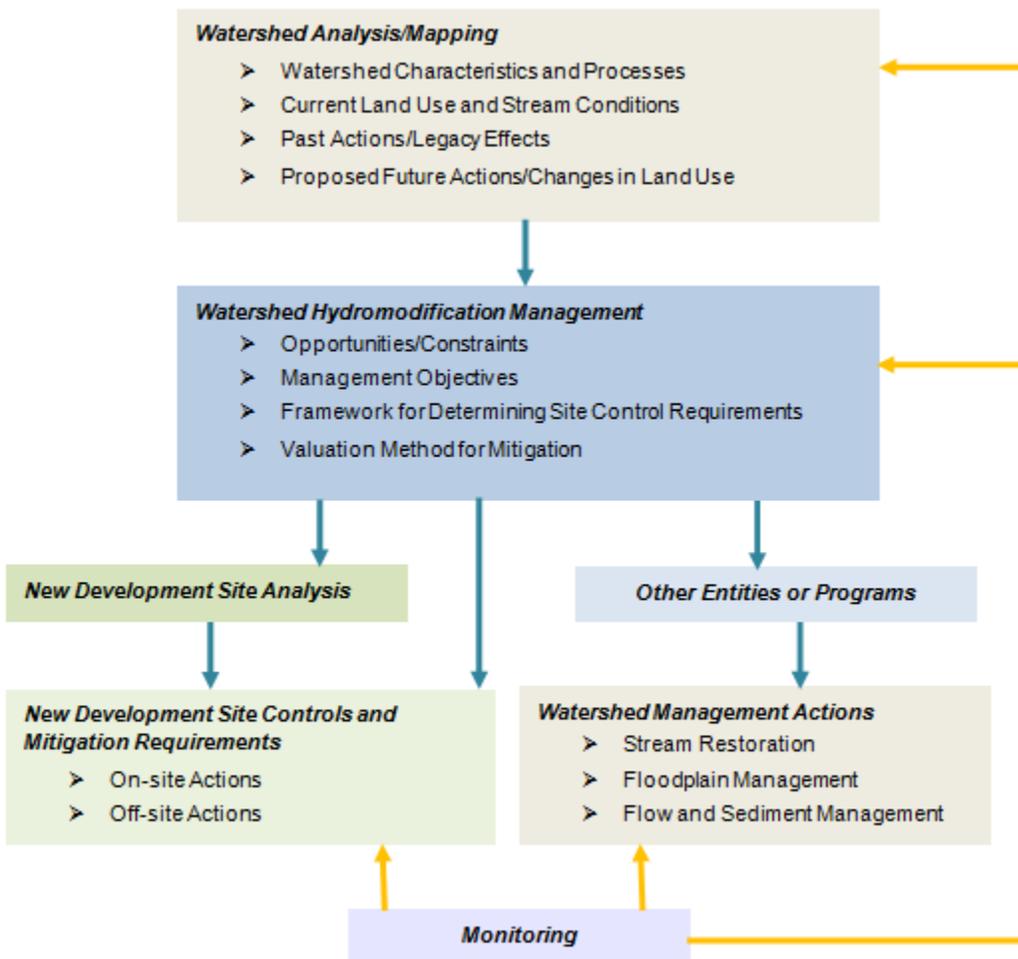

Figure 23. Framework for integrated hydromodification management

3.1 General Guidelines for Hydromodification Management

Hydromodification management plans should be developed around the following general principles:

- Hydromodification management needs to occur primarily at the watershed scale. The foundation of any hydromodification management approach should be an analysis of existing and proposed future land uses and stream conditions that identifies the relative risks, opportunities, and constraints of various portions of the watershed. Site-based control measures should be determined in the context of this analysis.
- Clear objectives should be established to guide management actions. These objectives should articulate desired and reasonable physical and biological conditions for various reaches or portions of the watershed. Management strategies should be customized based on consideration of current and expected future channel and watershed conditions. A one-size-fits-all approach should be avoided.
- An effective management program will likely include combinations of on-site measures (e.g., low-impact development techniques), in-stream measures (e.g., stream habitat restoration), and off-site measures. Off-site measures may include compensatory mitigation measures at upstream locations that are designed to help restore and manage flow and sediment yield in the watershed.
- Hydromodification control measures cannot be driven solely by new development and redevelopment, legacy effects should be remedied in order to restore watershed processes. This also means that management strategies will need to acknowledge pre-existing impacts associated with historical land uses. Restoration goals should be set in the context of existing and anticipated future constraints. This will allow for development of a reasonable set of expectations and restoration targets.
- Management measures should be informed and adapted based on monitoring data. Similarly, monitoring programs should be designed to answer questions and test hypotheses that are implicit in the choice of management measures, such that measures that prove effective can be emphasized in the future (and those that prove ineffective can be redirected).
- Hydromodification potentially affects all downstream receiving waters. For example, bays, harbors, and estuaries may be affected by excessive sediment input. These waterbody types should be considered in the development of hydromodification management plans and accounted for when developing watershed goals and objectives.

In many cases, relying solely on site-based flow control will not be wholly effective at addressing all hydromodification effects, particularly those associated with effects of past land-use practices. Management approaches should shift from a stream centered view of controlling erosion, deposition, and planform change to focus on restoring watershed processes that ensure movement of water and sediment in ways that help maintain the dynamic equilibrium of stream channels:

- Coarse sediment-supply areas should be protected and restored – Coarse sediments, such as larger sands, gravels, and cobbles can erode from hillslopes around streams via a variety of processes including dry ravel, erosion, and via overland runoff. Once in the stream, coarse materials play a substantial role at maintaining equilibrium of work within the channel and

reducing the erosive energy of flow on channel bed and banks. Maintaining these supplies is critical to long-term dynamic stability of stream channels.

- Coupling between sediment supply and transport reaches should be maintained or restored – Land use practices, such as housing, roads, and basins often intentionally or unintentionally disrupt or intercept the movement of sediment from hillslopes to floodplains and channels. For coarse sediment to be effective at helping to protect streams from hydromodification, the connection (or coupling) between hillslopes and floodplains must be maintained (or restored).
- Sediment-transport capacity should be maintained – Functioning stream systems facilitate movement of sediment from source areas to downstream areas of deposition that support habitat and encourage channel processes that reduce energy (e.g., meandering, multi-thread flow). The transport function of reaches that typically occur in the middle portions of watersheds should be maintained, managed, and restored (if necessary).
- Floodplain connections should be protected and restored – Floodplains perform a range of hydrologic and ecological functions. In middle- and higher-order streams in low-gradient settings, they are important areas of energy dissipation which function to help protect downstream areas from hydromodification. Maintaining connections between streams and their floodplains allows higher flows to readily access wide overbank areas which slow water and reduce energy.

Example areas that could be managed for each of the functions described above are shown in Figure 24. This more-integrative approach will require creation of mechanisms for placing management resources in the most appropriate portion of the watershed, which may not be at the specific project site being evaluated by a particular regulatory action (e.g., off-site mitigation, fee-based management programs).

Figure 24. Example areas within a watershed where individual process-based management actions may occur.

3.2 Watershed Analysis

Watershed analysis should be the foundation of all hydromodification management plans. Analysis should identify the nature and distribution of key watershed processes, existing opportunities and constraints in order to help prioritize areas of greater vs. lesser concern.

A general objective should be to identify watershed management zones based on key watershed processes and opportunities (e.g., infiltration, sediment yield). For most watersheds, they can be roughly divided into sediment source areas, transport reaches, and deposition/storage areas (Figure 25).

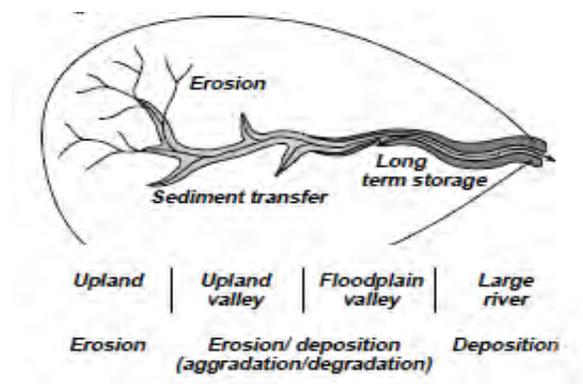

Figure 25. Conceptual functional zones of an idealized watershed (Church, 2002).

Within these general zones, priority activities should be based on a comprehensive watershed analysis. The overall objective of the mapping is to identify major opportunities, such as floodplain protection or restoration, in-stream restoration, protection of sediment-supply areas and major constraints, such as sensitive resources, infrastructure, impending headcuts or other catastrophic channel response.

Watershed analysis can occur at a variety of scales depending on available information and management objectives. In general, *analysis at a hydrologic unit code (HUC) 10 or HUC 12 watershed* provides a balance between analytical complexity and availability of management options. This scale will often translate to the size of tributary watershed upstream of major named rivers. Watershed analysis can also occur at a variety of levels of detail and resolution. Simple analyses that rely on readily available data layers such as stream and wetland maps, land use, existing infrastructure, geology, and slope can provide a valuable starting point for guiding management decisions. These initial maps can be augmented and expanded based on needs as additional information and resources become available.

Watershed analysis can occur at variety of scales and resolutions depending on management needs and available resources.

Mapping, and in some cases modeling, is the basis of watershed analysis and should include data layers to facilitate the following analyses. Most of these data layers are freely available online. Further information on analysis tools is provided in the next section. These maps should be designed for iterative updates over time as new information becomes available:

- Dominant watershed processes – analysis of topography (10-m digital elevation model), hydrology, climate patterns, soil type (Natural Resources Conservation Service (NRCS) soil classifications), and surficial geology can be used to identify the location and type of dominant watershed processes, such as sediment source areas and areas where infiltration is important or where overland flow likely dominates. This can provide a template for the eventual design of management measures that correspond most closely to the pre-development conditions, which support processes that promote long-term channel health.
- Existing stream conditions – At a minimum the NHD can provide maps of streams and lakes in the watershed. Additional information on stream condition should be included to the extent that it is available. This could include major bed-material composition, channel planform, grade control locations and condition, and approximate channel evolution stage. Where channel susceptibility analysis has been done, results should be included (see Bledsoe *et al.*, 2010, 2012)¹. These maps can also be used to conduct general stream power evaluations.
- Current (past) and anticipated future land use – Current land use and land cover plus proposed changes due to general or specific plans. Existing or proposed floodplain development should be noted. Historical information on past land use practices or stream conditions including historic channel locations or alignments should be included if readily available. Classified land cover (National Land Cover Dataset (NLCD), 2006) is available from the Multi-Resolution Land Characteristics Consortium (MRLC).
- Potential coarse and fine sediment yield areas – methods such as the Geomorphic Land Use (GLU) approach (Booth *et al.*, 2010) can be used to estimate potential sediment yield areas based on geology, slope, and land cover.
- Existing flood-control infrastructure and channel structures – maps should include major channels, constrictions, grade control, etc. that affect water and sediment movement through the watershed. Any available information on water quality, flood control, or hydromodification management basins should also be included. The location of engineered flood control channels and their design capacity should be noted.
- Habitat – both upland and in stream, and riparian habitat should be mapped to help determine areas of focus for both resource protection and restoration. This may be based on readily available maps such as the National Wetlands Inventory and National Land Cover Database, aerial photograph interpretation, or detailed local mapping.
- Areas of particular management concern – these may include sensitive biological resources, critical infrastructure, 303(d) listed waterbodies, priority restoration areas, or other locations or portions of the watershed that have particular management needs.
- Economic and social opportunities and constraints – comprehensive watershed management includes consideration of opportunities for improving community amenities associated with streams, economic redevelopment zones, etc. Details on this are beyond the scope of this report, but emphasize the need to include planning agencies in the development of hydromodification management plans.

¹ The channel susceptibility tools produce scores/ratings for both the vertical and horizontal stream dimensions. If there is a need to assign a single rating to a stream reach, the more-sensitive measure should be used.

Results of the watershed analysis should be used to address questions such as:

- What is the inherent susceptibility/risk of various stream reaches to hydromodification?
- Where are natural or developed resources of concern that need to be protected?
- What areas are good candidates for various restoration or management activities?
- What areas are not suitable or highly constrained for future restoration actions?
- What are the likely future changes in land use and associated runoff processes?

The answers to these questions can be used to determine the most appropriate management actions for specific portions of the watershed. Management strategies should be tailored to meet the objectives, desired future conditions, and constraints of the specific channel reach being addressed.

3.3 Types of Management Actions

Comprehensive hydromodification management should include on-site measures, upland protection or restoration, floodplain restoration and management, and in-stream restoration. These measures are summarized below; guidelines for selecting specific actions are provided in the following sections:

On-site measures – *typically applied throughout the watershed:*

- low impact development (LID) practices;
- disconnecting impervious cover through infiltration, interception, and diversion;
- coarse sediment bypass through avoidance of sediment yield areas or measures that allow coarse sediment to be discharged to the receiving stream;
- flow-duration control basins to reduce runoff below a threshold value.

Upland protection through planning processes – *prioritize in source areas of the watershed:*

- avoid coarse sediment yield areas;
- restore upland areas producing excessive fine sediment;
- protect infiltration areas; and
- construct regional basins or other retention facilities.

Floodplain and stream restoration and management – *prioritize in transport and deposition areas:*

- stream corridor restoration;
- restoration and/or protection of floodplain/floodway habitat;
- restoration and/or protection of critical sediment-transport areas;
- upstream or downstream natural/bio-engineered grade control; and
- retrofit or repair of currently undersized structures (e.g., culverts, bridge crossings).

3.4 Selecting Appropriate Management Actions

Management actions should be selected in consideration of the location where the change in land use is planned and the anticipated changes in watershed processes. The location of management actions should be prioritized based on established goals and targeting management actions to the location in the watershed where they will have the greatest potential effect (based on the watershed analysis). In general, a multi-level strategy combining actions at different scales and locations may be necessary. In

highly-developed watersheds, management actions may primarily consist of a combination of on-site and off-site flow-duration control facilities. In less-developed watersheds, there may be more opportunities for upland restoration, avoidance of sediment source areas, and floodplain restoration.

In general, it is more effective to try and “prevent” hydromodification effects through land use planning than attempting to manage effects through on-site or regional flow-duration control. In particular, upland restoration and floodplain management or restoration can be effective at reducing the need for aggressive or large-scale flow duration, as indicated in Table 5. Therefore, where opportunities exist, these strategies should be prioritized.

In general, it is more effective to try and “prevent” hydromodification effects through land use planning than attempting to manage effects through on-site or regional flow-duration control

Table 5. Runoff management decision matrices.

		upper watershed									
sensitivity of d/s resources:		high			moderate			low			
		expected change in runoff			expected change in runoff			expected change in runoff			
		high	medium	low	high	medium	low	high	medium	low	
channel susceptibility	high	[Red]			high	[Red]			high	[Red]	
	medium	[Red]		[Yellow]	medium	[Red]	[Yellow]		medium	[Yellow]	
	low	[Red]		[Yellow]	low	[Yellow]		[Green]	low	[Green]	
		middle/lower watershed									
sensitivity of d/s resources:		high			moderate			low			
		expected change in runoff			expected change in runoff			expected change in runoff			
		high	medium	low	high	medium	low	high	medium	low	
channel susceptibility	high	[Red]			high	[Red]			high	[Red]	
	medium	[Red]		[Yellow]	medium	[Red]	[Yellow]		medium	[Yellow]	
	low	[Yellow]		[Green]	low	[*]	[*]	[*]	low	[*]	[*]
[Red]	aggressive flow-duration control										
[Yellow]	moderate flow duration control										
[Green]	low-levels of flow duration control										
[*]	candidate for off-site mitigation										

- Notes:
1. Upper watershed generally refers to source areas whereas middle and lower watersheds refer to transport and deposition areas, respectively.
 2. Sensitivity of downstream resources, change in runoff, and channel susceptibility are determined through the watershed analysis process.
 3. High, Medium, and Low categories should be defined based on individual watershed or regional analysis in concert with stakeholder input.

Chapter 3 of SCCWRP Technical Report #667 *Hydromodification Assessment and Management in California* (Stein *et al.*, 2012) provides a detailed discussion of potential management endpoint and actions that can be taken at various scales to achieve those endpoints. The following subsections provide considerations for prioritizing management actions.

3.4.1 *On-site Flow Control Measures*

On-site flow-duration control should be considered a primary management measure to help meet erosion potential/load ratio targets in streams that are at risk for hydromodification effects. Where there is a chance of downstream erosion, on-site flow control can reduce effects of development on channel form and structure. However, the level of control (i.e., the volume of water retained) can be adjusted based on:

- Expected changes in flow between pre-project (not pre-development) and post-project conditions;
- Susceptibility of the stream channel into which the discharge will occur; and
- Sensitivity of downstream resources (both natural habitats and critical infrastructure).

In contrast, where sites discharge to fully engineered channels², in-stream erosion may not be the primary management concern. In these cases, water quality and/or sedimentation in downstream receiving waters may be the primary factor influencing the design of on-site control facilities. In these instances, resources for hydromodification management may be better allocated to regional facilities or to upstream restoration actions.

3.4.2 *Regional Flow Control Measures*

Projects that discharge directly to fully-engineered channels, confluence points with substantially-larger watersheds, bays, and estuaries may still contribute to downstream water quality effects, but may have minimal effect on in-channel erosion. Furthermore, the contribution from smaller projects at the terminus of watershed management units (e.g., HUC 10 or HUC 12 watersheds) may be relatively small compared to the cumulative upstream discharges. In such cases, minimal on-site impacts may be best mitigated through contributions to regional basins, large restoration projects, or other facilities. A variety of mechanisms can be used to support regional off-sets, such as off-site mitigation, in-lieu fees, impact feeds, or community facilities districts. An example framework for an accounting and tracking system for on and off-site mitigation facilities in Ventura County, California, is provided in Appendix A.

3.4.3 *Protection and Management of Floodplains and Adjacent Uplands*

Upland protection (i.e., activities outside the stream itself) can be prioritized by position in the watershed, based on opportunities and constraints identified during the watershed analysis. As stated above, the goal is to restore watershed process; consequently, actions should be targeted to the appropriate portions in the watershed:

² In some instances a site may discharge to an engineered channel, which eventually transitions to a more natural channel. In these cases, on-site flow duration control may still be appropriate. Decisions should be based on a consideration of all downstream reaches and not just those immediately adjacent to the project site.

Source areas (typically in the upper portions of sub-watersheds): To the extent possible, coarse sediment yield areas should be protected. Development activities should avoid these areas and allow yield areas to be coupled to the appropriate stream. Legacy effect areas that produce excessive sediment, such as heavily grazed or farmed uplands should be restored. *Some source areas may contain key infiltration zones that should be protected. Conversely some source areas are characterized by naturally-impervious surfaces – development should be targeted for these areas to minimize pre- vs. post-project changes in runoff.*

Transport reaches (generally in the middle portion of catchments): Stream corridors can be protected where they are still intact and restored where the opportunity exists. Key infiltration zones that often occur at the transition between source areas and transport reaches should be managed for this function.

Deposition areas (generally in lower catchments): Floodplains can be protected where they are still intact and restored where the opportunity exists in order to support storage and infiltration functions. Management and restoration actions should focus on restoring the connection between streams and their adjacent floodplains.

3.4.4 Stream Restoration

Management strategies should be tailored to meet the objectives, desired future conditions, and constraints of the specific channel reach being addressed. Objectives for specific stream reaches may include stream protection, restoration, or stabilization and management:

Protect: This approach consists of protecting the functions and services of relatively-unimpacted streams in their current form through conservation and anti-degradation programs. This strategy should not be used if streams are degraded, or nearing thresholds of planform adjustment or changes in vegetation community. This strategy may apply following natural disturbances such as floods depending on the condition of the stream reach and the ability for natural rehabilitation to occur (due to how intact watershed processes are). The goal of this strategy is not to create an artificial preserve (such as a created stream running through an urban park) but rather a naturally functioning river system.

Restore: Restoration is considered re-establishing the natural processes and characteristics of a stream. The process involves converting an unstable, altered, or degraded stream corridor, including adjacent riparian zone (buffers), uplands, and flood-prone areas, to a natural condition. In most cases, restoration plans should be based on a consideration of watershed processes and their ability to support a desired stream type. The watershed analysis discussed above should be used to determine how and where watershed process should be protected or restored in order to best support stream and stream-corridor restoration. Restoration should apply to streams that are already on a degradation trajectory where there is a reasonable expectation that a more stable equilibrium condition that reflects previously existing conditions can be recreated and maintained via some intervention. Creating a stream system that differs from “natural conditions” is not considered restoration. Restoration may not be feasible in portions of developed watersheds where processes and floodplains have been irrevocably altered. In those cases, management, as a new channel form may be a more appropriate goal (see below).

Stabilize and manage as a new channel form: Once a stream channel devolves far enough down the channel evolution sequence, it is extremely difficult to recover and restore without substantial investment of resources. If critical thresholds in key structural elements, such as planform or bank height, are surpassed, streams should be allowed to continue progressing toward a new stable equilibrium condition that is consistent with the current setting and watershed forcing functions, if such progress does not pose a danger to property and infrastructure. Substantial alteration of flow or sediment discharge, slope or floodplain width may make it improbable that a stream can be restored to its previous condition. In such circumstances, it may be preferable to determine appropriate channel form given expected future conditions and “recreate” a new channel to match the appropriate equilibrium state under future conditions. For example, a multi-thread braided system may not be the appropriate planform based on new runoff and sediment pattern; instead, a single-thread channel or step-pool structure may be a more appropriate target.

The decision about which endpoint is most appropriate should consider a variety of factors relative to stated goals and objectives for each stream and the existing and expected landscape constraints. Table 6 provides general guidelines on the most appropriate strategy based on a variety of factors. The criteria listed in the first column are defined and assessed via the watershed analysis (previously discussed). The High, Medium, and Low criteria should also be defined through watershed analysis and modeling, in concert with watershed stakeholders.

Table 6. Relationship between various stream management endpoints and contributing factors. H = High, M = Medium, L = Low, which are defined based on the results of the watershed analysis and agreed upon objectives.

	Protect	Restore	Stabilize & Manage
existing channel condition (CEM)	I, II	II, III	IV, V
susceptibility class (screening tool)	L	M	H
available floodplain	H	H, M	L
buffer opportunity	H	H, M	L
instream natural resources	H	H, M	L
downstream resources	H	H, M	L
connectivity of stream corridor	H	H, M	L
future discharge relative to reference	L	L	M, H
sediment supply	H	H, M	L

In practice, a stream should be evaluated for each of the criteria in the first column. Stakeholders can add criteria to the decision matrix based on what is important in their area. Furthermore, criteria can be weighted differentially based on local priorities. The predominant condition for a given location should be used to inform the selected management endpoint. An example application is shown in Table 7.

Table 7. Sample application of the relationship between various stream management endpoints and contributing factors. H = High, M = Medium, L = Low, which are defined based on the results of the watershed analysis and agreed upon objectives. Shading indicates selections for a hypothetical example (see Figure 26). The majority of criteria in this example suggest that a restoration endpoint is appropriate for this stream reach.

	Protect	Restore	Stabilize & Manage
existing channel condition (CEM)	I, II	II, III	IV, V
susceptibility class (screening tool)	L	M	H
available floodplain	H	H, M	L
buffer opportunity	H	H, M	L
instream natural resources	H	H, M	L
downstream resources	H	H, M	L
connectivity of stream corridor	H	H, M	L
future discharge relative to reference	L	L	M, H
sediment supply	H	H, M	L

Hydromodification Management Decision Process

STEP 1 – opportunity for sediment-supply protection and if so, take advantage

STEP 2 – assess channel susceptibility using screening tool

STEP 3 – identify downstream resources of concern and opportunities for restoration

STEP 4 – predict E_p change under unmitigated conditions – can use gage data, regional curves or model

STEP 5 – use E_p change to estimate enlargement for the channel susceptibility class using models/curves (include confidence estimates)

STEP 6 – select size/aggressiveness of BMP/LID

STEP 7 – explore opportunities for off-site mitigation (e.g., regional basins, floodplain restoration, etc.)

STEP 8 – if necessary, and options available – pursue in-channel restoration

Note – STEPS 6, 7, and 8 should be done in concert with each other. Once the suite of management solutions are selected, return to STEP 4 and re-evaluate change in E_p under the mitigated condition.

Figure 26. Hypothetical example of summary of elements of the decision process for determining hydromodification management actions (flow control, upland restoration, stream restoration).

3.5 Decision-Making Conclusions

To improve the likelihood of long-term recovery and protection of beneficial uses, hydromodification management will need to evolve from a narrow focus on flow control to a more integrated approach that focuses on restoration of watershed processes and remediation of past and anticipated future instream effects. Integrated management relies on a watershed analysis that identifies key opportunities and constraints that can be used to prioritize the location and type of management actions. Such watershed analysis can range from simple to complex depending on goals, needs, and available resources.

Unfortunately, the current regulatory and management structure may not always be well suited to implement an integrated watershed-based management approach. Transitioning from site-based to watershed based management may require changes in the development and application of hydromodification policies and plans by the State and Regional Water Boards and local jurisdictions. In the short term, municipalities will need to consider broadening the approaches to on-site management measures and expand monitoring and adaptive management programs based on the tools described in this document. In the long term, regulatory agencies will need to consider developing watershed-based programs that allow for implementation of management measures in the locations and manner that will have the greatest impact on controlling hydromodification effects. A watershed-based approach will also allow the integration of hydromodification management objectives with related programs such as water-quality management, groundwater management, and habitat management and restoration through mechanisms such as Integrated Regional Water Resources Management Plans. A logical next step is to demonstrate the application of integrated hydromodification management through stakeholder driven development of prototype watershed-based management programs. These early efforts will be valuable in guiding early implementation and refining the concepts presented in this document.

INTRODUCTION

This memo is intended to provide agencies with information and options to develop an accounting and tracking framework for the mitigation of the Permit's Low Impact Development (LID) requirement. It is broken out into a brief background on the requirements and the estimated need for offsite mitigation across the county; the challenges of implementing offsite mitigation at different scales; an examination of programmatic and funding approaches; and the administration and accounting options available to public agencies.

BACKGROUND

The Ventura Countywide National Pollutant Discharge Elimination System (NPDES) Municipal Separate Storm Sewer System (MS4) permit (Order R4-2010-0108) allows technically infeasible new development and redevelopment projects to use alternative compliance measures if onsite retention and/or biofiltration best management practices (BMPs) cannot feasibly be used to meet the 5% Effective Impervious Area (EIA) standard.

Alternative compliance is based on the "mitigation volume." The mitigation volume is the difference between the volume of runoff associated with 5% EIA and the volume of runoff associated with the actual EIA achieved onsite less than or equal to 30% ($\leq 30\%$) EIA. The offsite mitigation requirement for EIA in excess of 30% ($>30\%$) is 1.5 times the amount of stormwater not managed onsite.

Reporting Requirements

According to the NPDES MS4 permit, Permittees must provide a list of offsite mitigation projects available for funding to project applicants. Reporting requirements include: a schedule for the completion of these projects, including milestone dates to fund, design and construct the projects; and the mitigation funds raised to date and pollutant and flow reduction analyses prepared by project applicants that illustrate that the results are comparable to what would have been achieved by meeting the 5% EIA standard onsite.

Summary of Projected Need

As a first step, the potential extent of mitigation needs was estimated by developing countywide growth projections, estimating the volume of offsite mitigation needed, estimating the size of BMP structures needed, estimating the costs to design and build, and identifying interagency areas of influence. This estimate determined the need for offsite mitigation ranges from minimal in some municipalities down to nonexistent for offsite mitigation in other municipalities. A summary of projected new development and redevelopment acreage requiring offsite mitigation is provided in **Tables 1 and 2**. The projected need is an approximate estimate and is subject to alteration depending on zoning or General Plan modifications, and rate of and type of future new development and redevelopments. Additional details on the projected need are provided in **Attachment C**.

Table 1. Estimated Offsite Mitigation Need by 10-digit Hydrologic Unit Code (HUC)

10-Digit HUC	Mitigation Volume		
	ft ³	ac-ft	gallons
Calleguas Creek	199,500	5	1,492,000
McGrath Lake-Frontal Pacific Ocean	85,900	2	642,400
Ventura River	19,000	0.4	141,900
Los Sauces Creek-Frontal Pacific Ocean	12,700	0.3	95,100
Lower Santa Clara River	7,800	0.2	58,600
Middle Santa Clara River	4,700	0.1	35,100
Malibu Creek	100	0.02	600
Upper Los Angeles River	0	0	0
Lower Piru Creek	0	0	0
Big Sycamore Canyon-Frontal Santa Monica Bay	0	0	0
Total	329,700	8	2,465,700

Table 2. Estimated Offsite Mitigation Need by Permittee

Permittee	Mitigation Volume		
	ft ³	ac-ft	gallons
Simi Valley	149,300	3	1,116,500
Oxnard	73,100	2	547,100
Camarillo	44,800	1	335,000
Unincorporated County Urban Areas	18,900	0.4	141,300
Ventura City	11,100	0.3	82,800
Thousand Oaks	10,600	0.2	79,300
Ojai	8,300	0.2	62,100
Moorpark	4,300	0.1	32,100
Santa Paula	3,900	0.1	28,900

Permittee	Mitigation Volume		
	ft ³	ac-ft	gallons
Port Hueneme	3,100	0.1	23,000
Fillmore	2,300	0.1	17,600
Total	329,700	8	2,465,700

These findings have several implications for the development of an offsite mitigation framework:

- The relatively small need projected for offsite mitigation diminishes the need for regional BMPs.
- It may be more cost effective and manageable for municipalities to meet the need with the implementation of just a few small offsite BMPs.
- The offsite mitigation framework should be flexible and adaptable enough to accommodate a variety of future growth scenarios.

Permit Provisions & Project Eligibility Criteria

Criteria for eligible offsite mitigation projects were recently developed by Permittees as part of a call for projects that solicited opportunities for regional offsite mitigation projects from interested stakeholders. The NPDES MS4 permit requirements guided the development of the eligibility criteria. The eligibility criteria combined with the estimated need is useful for identifying viable offsite mitigation options for Ventura County permittees. Relevant criteria for eligible projects include:

- Offsite projects must be located in Ventura County and within the same Hydrologic Unit Code (HUC).
- Offsite projects must be located such that the offsite mitigation project would achieve equivalent stormwater volume and pollutant load reduction as if the new development and redevelopment projects that will utilize the proposed alternative compliance project had complied with subparts 4.E.III.1.(a)-(d) of the permit. Project locations which can receive runoff from existing urban development meet this criteria.
- Offsite projects must be designed to retain and/or biofilter runoff from existing urbanized areas. In general, this should be accomplished via infiltration measures; however, stormwater harvesting and biofiltration will be considered on a site-specific basis. BMPs must be designed in accordance with the design guidance in the 2011 Technical Guidance Manual (TGM).
- Offsite mitigation projects may include green streets projects, parking lot retrofits, other site specific BMPs, and regional BMPs.
- Offsite mitigation projects must be able to be completed within 4 years of the certificate of occupancy for the first project that contributed funds toward the construction of the offsite mitigation project, unless a longer period is otherwise authorized by the Regional Water Board Executive Officer.

OVERVIEW OF PROJECT-SPECIFIC CHALLENGES

Several challenges exist that have the potential to constrain the type of offsite mitigation projects implemented by Permittees. One of the principle challenges in designing a funding mechanism for the proposed offsite facilities is the unpredictability of the timing of the need for the facilities. Several likely scenarios exist and are discussed below:

Scenario 1: Large Regional Facility

A large, regional multi-municipality facility, potentially involving multiple (roughly more than three) development projects, poses clear funding challenges and risks. Since development projects are difficult to predict in terms of size and timing, both the size and schedule for investment would be difficult to predict and manage, accordingly. In particular, permit requirements to achieve the minimum EIA technically feasible onsite combined with a small projected need are likely to limit the participation in regional facilities. The NPDES MS4 permit requires that offsite mitigation projects be completed “as soon as possible, and at the latest, within four years of the certificate of occupancy for the first project that contributed funds towards the construction of the offsite mitigation project.” The four year timeline makes the implementation of regional facilities challenging because it is likely that Permittees will have to construct a regional facility before a sufficient, “critical mass” of funds are received from developers.

It may take several years for a permittee to work with developers and accumulate the funds necessary for the design, construction and permitting of a regional facility. In addition to the uncertainty associated with funding, completing the construction of a regional facility in four years may be difficult given the length of time it takes to acquire necessary permits.

However, since there may be economic advantages resulting from the efficiencies of scale of a large, regional facility, this scenario, although not optimal, should not necessarily be discounted. A regional facility may be feasible if a permittee or a group of permittees felt that they could predict development size and timing and then build a facility to suit. As new development projects arose, and participated in the offsite mitigation, they could be required to pay their portion, plus interest, of the regional facility. In essence the municipalities would serve a developer/ bank, speculatively building the facility, but planning on recouping all of their investment from future development.

Water supply facilities are often set up using this approach in areas where development is predicted. The water supply agency designs and installs water treatment and piping capacity that is larger than needed, speculating that future development will occur, and can be tapped to reimburse the agency’s capital costs. Of course, this “build it and they will come” approach is particularly vulnerable to the risk that predicted future development does not occur, and the costs of the unused regional facility would be incurred by the Permittee.

Scenario 2 – Midsized Facility

Smaller, midsized facilities involving two or three developers may offer many of the offsite mitigation advantages without the same significant financial risk as regional facilities. Because of the smaller, more manageable number of participants, financing arrangements could be established and designed prior to design, construction and operations. This project would have to be completed within the four year window, as stipulated in the permit. As an example, a

municipality may elect to construct a retrofit on public land (e.g., bioretention area in parking lot) that could provide offsite mitigation for two or three developers.

Scenario 3 - Small Development Project-Specific Facility

Individual, development project-specific would allow the maximum control and the least financial risk to the municipalities in terms of establishing a funding mechanism. The entire financing arrangement would be established and designed prior to design, construction and operations. The primary disadvantage of this scenario is that it potentially results in a relatively high implementation cost to the developer. Additionally, the small amount of mitigation volume that is likely to result on a per project basis may not warrant the creation of a standalone BMP such as an infiltration trench. However, given the right set of site conditions, it could support the implementation of a small BMP such as a tree-well filter in the right-of-way located in front of the development project. This is further discussed under the option, “Developer Mitigates Offsite.”

PROGRAMMATIC/ FUNDING APPROACHES

The following section explores several options available to Permittees for an offsite mitigation funding framework. A survey was conducted in November 2011 to get an idea of what each permittee is considering for an offsite mitigation framework. The results of this survey (see **Attachment B**) were used to help determine the offsite mitigation framework options. Additionally, a review of other offsite programs was conducted and summarized in **Attachment A**. These programs included non-stormwater offset programs already being conducted by Permittees (e.g., parks) and stormwater quality offsite mitigation programs located outside of Ventura County. Aspects of these programs were incorporated into the options described below.

A description, advantages, and disadvantages are described for each funding approach (O&M and tracking discussed separately in next section):

- Developer Mitigates Offsite
- Purchase Credits through Private Seller
- In-Lieu Fee
- Impact Fee
- Community Facilities District
- Effective Combinations
- Additional Considerations that Cross Multiple Options

Developer Mitigates Offsite

Under this option, the developer is responsible for constructing a stormwater BMP offsite that will retain or biofilter the mitigation volume. Two primary scenarios exist under this option.

Developer Builds Offsite Mitigation Project on Private Property

The primary advantage of this approach is that it results in a potentially reduced burden on the Permittee, particularly if the developer or another third party is responsible for operation and

maintenance (O&M). Permittees will still have to ensure that the developer constructs a BMP that meets the intent of the permit and retains or biofilters the mitigation volume.

There are several disadvantages exist for this scenario. One disadvantage is that developers might have difficulty identifying a feasible offsite mitigation project within the municipality (or HUC). This could result in a high transaction cost for the developer and may introduce uncertainty into the project approval process and timeline. Additionally, since the offsite mitigation project is located on private land, the owner of the land must be willing to accept the liability and O&M associated with the project. Additional tracking is required to ensure that if the offsite location is redeveloped that the retained volume is not credited to the redevelopment.

Developer Builds Offsite Mitigation Project on Public Property

Under the second scenario, Permittees generate a list of options available to the developer on public land. The advantage of this scenario is that it reduces the burden on the Permittee and the developer (relative to other options). In this scenario, the developer takes on the responsibility of constructing the BMP, but their burden is reduced since they are not left with trying to find a viable retrofit opportunity. Permittees may provide the design and the location of the offsite mitigation project or just the location. This scenario is particularly desirable if the developer is able to implement a small BMP in the right-of-way such as a tree-well filter.

There are a few disadvantages to this scenario. Given the small offsite mitigation likely needed on a project-by-project basis it may not be technically or financially effective for each project to construct a standalone BMP such as an infiltration trench. It may also be undesirable if the public perceives this scenario as a donation of public land to developers (i.e., viewed as favoring certain developers). However, it is not uncommon for a municipality to dedicate land to developers for other public infrastructure projects such as parks or schools. Finally, the Permittee would likely be solely responsible for O&M costs. Additional options for O&M discussed under Program Administration.

Purchase Credits through Private Seller

This option requires a private company to take on the liability of mitigation, responsibility for O&M, and certify that offsite mitigation will be completed within four years of the certificate of occupancy and located within the same HUC. A private company can sell mitigation credits by either:

- Exceeding the volume they are required to retain onsite (i.e., they harvest and use more than the SQDV onsite)
- Retrofitting an unregulated site (i.e., currently has no stormwater quality management)

A private seller-oriented program would likely include the following steps:

- The developer proposing to purchase credits from a private seller documents the amount of mitigation volume needed and how it will be met using private mitigation (e.g., 120 street trees planted = 50 gallons mitigated). This documentation is included as part of the post-construction plan review submittals.
- The developer pays private company directly.
- The private company conducts mitigation (e.g., constructs retrofit).

- The private company reports to Permittee when the offsite mitigation project is completed.
- Permittee must verify that the BMP meets intent of permit provisions and has “credits” to sell.

The primary advantage of this approach is that the cost of the offsite mitigation project, including construction and O&M, is financed by private sector investors seeking to profit by selling credits. The credit system being considered by Washington DC is summarized in Attachment A.

There are several disadvantages to this approach. Given the small projected need for offsite mitigation, it is unlikely that it could support a marketplace of private sellers offering credits to developers within the HUC. Likewise, if this is the only option available to developers, Permittees may need to invest some time at the outset of the program to help foster an offsite mitigation credit marketplace (e.g., helping private sellers identify potential offsite mitigation opportunities). Additionally, an up-to-date tracking system would be necessary in order to ensure that available and used credits are accurately tracked to ensure that double-counting does not occur.

Reimbursement Agreement

Under this option, a developer that is eligible for offsite mitigation opts to construct an offsite mitigation facility that meets and exceeds their mitigation volume. Permittees may direct willing developers to a specific project that they have in mind. To facilitate cost sharing, the developer requests a reimbursement agreement with the City. When other developers eligible for offsite mitigation are identified by the permittee, the permittee collects and transfers an amount identified in the reimbursement agreement to the developer that entered into the reimbursement agreement. The amount should be in keeping with the facility’s available mitigation volume. This option is commonly used in Thousand Oaks for the extension of water and wastewater utilities.

The primary disadvantage of this approach is finding a developer willing to construct a facility that exceeds the required mitigation volume and who is willing to take on some uncertainty associated with payback. This option also does not create a straightforward mechanism for ensuring long-term O&M. One scenario may be to combine this option with a CFD tax that will cover O&M costs associated with the facility.

Negotiated Mitigation Agreement

A negotiated mitigation agreement (also commonly referred to as an in-lieu fee) between a developer and a public agency is a common and flexible approach to addressing mutual infrastructure and service needs. This approach, which may also be called a “mitigation fee”, “cash-out” involves the developer making a one-time payment associated with the mitigation, “in lieu” of meeting permit requirements onsite, or satisfying the associated financial obligation in some other way. Permittees collect and use these funds to identify, design and construct and manage offsite mitigation projects. These funds could also be used towards existing projects that currently retain more stormwater runoff volume than required or retrofit of an existing BMP to provide additional retention. To minimize local developer opposition or concerns from elected officials, the payment structure should be transparent and directly correspond to the costs associated with constructing and maintaining an offsite mitigation project.

A negotiated mitigation agreement/in-lieu fee is straightforward and usually accomplished by an ordinance (or modification to an existing ordinance) approved by a Council or Board of Supervisors. Recommendations for the adjustment or increase of a flat mitigation agreement will require approval by Council/Board of Supervisors. A nexus must also be created between the agreement and the Building or Grading permit. To reduce the frequency that the negotiated mitigation agreement/in-lieu fee must be adjusted via Council, calculation of the payment should include an inflation adjustment factor. Several existing mitigation fee programs within the County require that payment account for inflation using the construction cost index for Los Angeles as published by the Engineering News Record/McGraw-Hill Construction Weekly.

Two primary scenarios exist under this option:

- Flat Mitigation Agreement/In-Lieu Fee:** Under this scenario, Permittees develop a flat dollar amount per gallon of stormwater runoff that could not be retained or biofiltered onsite. The majority of communities with stormwater offsite mitigation programs utilize this approach (Attachment A). Payment is set so that it encompasses a variety of likely design and BMP scenarios. To provide consistency and transparency, it may be desirable to determine a Countywide fee versus a Permittee-by-Permittee or project-by-project one. Preliminary cost estimates based on capital costs for an infiltration trench and infiltration basin were calculated as part of the Offsite Mitigation Need Memorandum (see Attachment C). The memo determined the cost by volume to be approximately \$1.55 to \$3.65/ gallon. These numbers do not include the cost of land acquisition which could vary widely by permittee.

Example: Use of Flat Mitigation Agreement to fund Capital Costs and O&M costs:

Assumptions:

Capital Costs Offsite Facilities	= \$750,000 (generalized across BMP types)
# of Gallons Treated by Offsite Facility	= 150,000 (generalized)
Maintenance and Operations Costs	= \$750,000 (10% of capital costs/ yearly for 10 yrs)

Results:

Flat In-Lieu Fee	= $(750,000+750,000)/155,000 = \$10/\text{gallon}$
------------------	--

- Project Specific In-Lieu Fee:** This scenario is also known as a market driven model where Permittees design, construct, and maintain the offsite mitigation project and recoup the costs for the project from a negotiated mitigation agreement. Payment is determined on a project-by-project basis and will therefore vary for each project. Discussion with other mitigation fee programs located within the County indicated that offsite mitigation programs are less administratively burdensome when funds are directed towards a pre-identified project.

Example: Project Specific Negotiated Mitigation Agreement to fund Capital Costs and O&M costs:

Assumptions:

Capital Costs Offsite Facilities	= \$750,000 (actual cost of BMP)
# of Gallons Treated by Offsite Facility	= 150,000 (actual)
Maintenance and Operations Costs	= \$750,000 (10% of capital costs/ yearly for 10 yrs)
Participating Developers	= 3 (assume equal need for offsite mitigation)

Results:

Project Specific In-Lieu Fee	= $(750,000+750,000)/155,000 = \$10/\text{gallon}$
Cost to each Developer	= \$50,000 (5,000 gallons each at \$10/gallon)

This approach has several advantages. This program allows funds to go to the Permittee which gives Permittees the ability to strategically direct retrofit efforts to priority areas (e.g., areas where infiltration is desirable). It also allows for the creative and flexible use of funds towards projects that work to reduce an equivalent volume of urban runoff. Options could include a street tree planting program or tax credits to homeowners that install LID practices on their property.

Additional advantages include reduced uncertainty from the developer's end. Once an agreement is determined, the developer's compliance is simple to calculate. Additionally, O&M responsibility is usually shifted to Permittee which provides certainty for the long-term function of the BMP.

The primary disadvantage of this option is that the administrative and long-term maintenance burden falls on the Permittee. A flat mitigation agreement/in-lieu fee is also challenging to identify and set so that it fairly recoups the costs associated with a wide range of projects. As an example, a Permittee may opt to implement an expensive harvest and reuse project or a modest infiltration project. The flat in-lieu fee must be able to cover the costs of both types of projects. In-lieu fees cannot be collected annually to support O&M so an established fee will have to incorporate the estimated future costs associated with O&M and inflation.

Additionally, some uncertainty exists for Permittees' ability to recoup the costs of BMP design, engineering, permitting, construction, and O&M for regional and midsized facilities. This is particularly true for offsite mitigation projects where construction is necessary prior to all the funds coming in from multiple developers.

Impact Fee

Similar to in-lieu fees, impact fees are one-time-only capital infusions. Impact fees are typically used to defray the cost of public facilities related to development projects (e.g., traffic impacts or affordable housing needs associated with commercial construction) versus a fee in-lieu of a development-specific requirement. These fees are often collected when the building permit is issued. The main disadvantage is that impact fees must adhere to Government Code Section 66000 (also known as the Mitigation Fee Act). This adds an additional layer of requirements including extensive public reporting.

Another disadvantage of implementing an impact fee is addressing any opposition from local developers and garnering support from the City Councils and/or Boards of Supervisors. However, since this impact fee would only affect a self-selected project, no resistance is expected from local developers nor elected officials so long as the fee bears a reasonable

relationship to the offsite facility. Unfortunately, impact fees cannot be collected annually to support O&M so an established fee will have to incorporate the estimated future costs associated with O&M and inflation.

It should be noted that impact fees implemented by a municipality often serve as the basis for negotiations that result in an in-lieu fee, because of the preferred flexibility available of an in-lieu fee.

Example: Impact Fees to fund Capital Costs (in combination with a CFD to fund O&M costs):

Assumptions:

Capital Costs Offsite Facility	= \$750,000		
Payback Period	= NA		
Maintenance and Operations Costs	= \$10,000 per year		
Participating Developers	= 3 (assume equal need for offsite mitigation)		

Results:

Impact Fee	= (750,000)/3	=	\$250,000
Annual Rate CFD O&M Rate	= (10,000)/3	=	\$ 3,333

Community Facilities District (CFD)

Ventura County currently has many localized special taxes, benefit assessments and fees (including the current funding mechanism for stormwater management) that fund the installation, maintenance and operations of various local infrastructure. These appear as “direct charges” on Ventura County property tax bills. The special taxes are primarily Community Facilities Districts (more commonly known as CFDs or Mello-Roos Districts), and the assessments are primarily Landscaping and Lighting Assessment Districts (LLADs). Both CFDs and LLADs are very effective and manageable, and are commonly used to fund maintenance of perimeter landscaping improvements for larger residential developments throughout the State. Most importantly, they are routinely established during the residential development phase, while the developer owns all of the property (and all the votes, accordingly), because they are politically challenging, requiring a balloting of all affected property owners, after the individual developed properties have been sold.

Since LLADs are more costly and difficult to set up, more limited in their use, and have greater legal risk than CFDs, they are not discussed further here. The only real advantage the LLADs have over CFDs is the arguably unfair negative reputation of Mello-Roos which arose during production house building in Southern California in the 1980 and 1990s; when homeowners felt duped by Mello-Roos charges as hidden costs. This should not be a factor regarding this offsite mitigation project.

CFDs can be set up by the Permittee, and are straightforward and well-proven. They require the development of a “Rate and Method of Apportionment” which documents the specific fee amount for a particular type of property and size; three resolutions, a tax report and ballot.

Properties can readily be annexed into a CFD and need not be contiguous – an important consideration for this project. Similar to in-lieu fees, they can include an option to adjust on an annual basis to reflect inflation and can include expiration dates called “sunset provisions” which corresponding to the payoff of capital costs.

In this case, a countywide or citywide “parent” CFD could be established which readily facilitates future annexations of specific development projects supporting specific BMP costs. On the other hand, specific CFDs could be setup for each specific development project. It typically takes about four months to implement the initial “parent” CFD and two months for each individual annexation.

Revenue from the CFDs can be used to pay back capital costs, as well as for O&M. A lien is placed on the propert(ies) subject to the CFD which helps ensure payment in the future, although the Permittee may have to finance the construction. Typically the rate is set to payback the capital component over a number of years in addition to maintenance. CFDs can be used as the underlying financial mechanisms to support the sale of bonds, although that is not likely in this case.

Although CFDs are highly reliable funding mechanisms, there are several disadvantages including the need for the Permittee to finance the proposed facility because the CFD tax will likely not generate enough revenue in the first year to pay for design, construction and permitting. The cost of establishing, and then annually managing the administration of the CFD tax, is not trivial, and may be several thousand dollars per year. These costs must be balanced against the cost of the annual maintenance which may be less. In any case, the annual administration can and should be included in the tax rate to ensure that all Permittee’s costs are recovered. It is worth noting that many Permittees (e.g. Moorpark) within the County already manage multiple CFDs and/or LLAD districts, so these administration costs can be shared and reduced. Also, similar to several of the other proposed funding mechanisms, the Permittee is burdened with the responsibility of the design, construction and permitting and O&M of the facility.

Example: CFD to fund Capital and O&M costs:

Assumptions:

Capital Costs Offsite Facility	= \$750,000
Payback Period	= 20 years
Maintenance and Operations Costs	= \$10,000 per year
Participating Developers	= 3 (assume equal shares)

Results:

Annual Rate for Year 1 thru 20	= $((750,000/20) + (10,000))/3$	=	\$15,833
Annual Rate for year 21 +	= $(10,000)/3$	=	\$ 3,333

Note: this simple example does not include financing costs

Effective Combinations

Permittees may want to consider combining several of the options presented above in order to maximize advantages and minimize the disadvantages. CFDs in particular can be combined with a number of the options presented above in order to provide a long-term source of funding for O&M. Impact fees and in-lieu fees can be used to collect funds from the developer to construct offsite facilities and supplemented with a CFD tax that provides funding for O&M via future property owners. This option is attractive to the Permittee since funding is received upfront for the construction of the facility (versus spreading it out over 20 years) and funding is provided

over the long-term for O&M. Similarly, this option is likely to be attractive to developers since the cost of O&M is directed to future property owners.

Another option may be to combine the private seller option with the developer mitigates offsite option. In this case, a developer constructs a sizeable facility that exceeds the amount of mitigation required by their development site. The developer is then able to sell off credits to other developers for a profit (this is similar to the “Reimbursable Agreement” option).

PROGRAM ADMINISTRATION AND ACCOUNTING

Several options for administering the accounting and programmatic aspects of an offsite mitigation program are described below.

Program Administration

Administering an offsite mitigation program requires several considerations including whether or not projects will be allowed to go outside the municipality, how tracking and reporting will be handled, and who will be responsible for O&M. These aspects of program administration are discussed in further detail below. The most likely options include municipality-by-municipality operated program or a Joint Powers Authority (JPA). If municipalities opt to allow offsite mitigation projects to occur watershed-wide, but do not establish a JPA other mechanisms such as memorandums of understanding (MOUs) will be required to address exchange of funds, maintenance responsibilities, etc.

Cross-Municipality Coordination

Allowing offsite mitigation projects to go outside of the municipality (but stay within the HUC) can increase flexibility and the number of options available to developers and Permittees alike. It also fosters a countywide approach that creates a level playing field for developers seeking offsite mitigation throughout the County. If offsite mitigation projects are allowed to occur within the HUC, several programmatic aspects must be addressed including tracking, exchange of funds, liability, and O&M responsibility.

If in-lieu fees, impact fees and/or CFDs are used to provide funding for construction and/or O&M, the funds will have to be collected by the municipality in which the development project takes place and then transferred to the municipality where the mitigation occurs.

At a minimum, municipalities that are willing to coordinate offsite mitigation projects on a watershed-wide basis should establish a MOU that documents mutually acceptable arrangements. The Calleguas Creek watershed is one example where it may be beneficial for multiple municipalities to coordinate offsite mitigation efforts. Coordination and exchange of funds across municipalities may be best facilitated through the establishment of a JPA (discussed in further detail below). Additionally, a countywide tracking program should be established in order to track the amount of mitigation volume available for each project.

Joint Powers Authority (JPA)

A JPA is an entity permitted under California law where two or more municipalities operate collectively. A JPA has a separate Board of Directors and is given powers, including taxing and planning authority authorized by an agreement typically referred to as a joint powers agreement. The term, membership, and standing orders of the Board of the JPA must be specified in the

agreement. The JPA may employ staff and establish policies independent from their participating jurisdiction. JPAs allow the pooling of resources between two or more municipalities that are working together to address an issue that transcends municipal boundaries.

JPAs offer several advantages to an offsite mitigation program. Under a JPA, municipalities located within the same HUC would be able to more easily combine in-lieu or impact fees, and CFD taxes received from developers and therefore reduce the uncertainty of recouping the funds necessary to construct an offsite mitigation project.

Tracking & Reporting

Some level of tracking will be necessary regardless of the offsite mitigation option selected in order to ensure that the mitigation volume needed is matched up with the mitigation volume provided. Tracking becomes particularly important if offsite mitigation projects are allowed to go outside of the municipality and/or if credits are available for purchase through a private seller. Both options require an up-to-date tracking system to ensure that available and used credits are accurately tracked to ensure that double-counting does not occur. In the case of cross-municipality offsite mitigation, a countywide (or watershed wide) tracking program may be necessary to track the amount of mitigation volume available for each project.

Administration Costs

Permittees should consider mechanisms to recover the costs associated with administering an offsite mitigation program. This includes additional plan review time, review and oversight of acceptable offsite mitigation projects, tracking offsite mitigation projects and available mitigation volume, and annual reporting. Permittees should consider either incorporating these costs into an in-lieu fee or as an administrative fee charged as part of the plan review process. If possible, these fees should include the cost associated with education and outreach as discussed under private O&M responsibility below. In cases where the developer mitigates offsite, allowances should be made for the Permittee to recoup administrative costs

Discussions with other mitigation fee programs located within the County indicated that plan review time is recouped by directly billing the developer the time spent reviewing each individual project (hourly rate * hours spent on review).

O&M Responsibility

Any selected option must take into account how the offsite mitigation project will maintain function over the long-term. O&M considerations apply to permittee maintained offsite mitigation projects, privately maintained projects, and projects that cross municipal boundaries.

Permittee Maintained

O&M responsibility with the Permittee provides the greatest certainty for BMP maintenance, but presents challenges when determining how to adequately recoup O&M costs from the developer and/or property owner. Permittees should incorporate the cost of O&M and associated inflation into any in-lieu fees and/or CFD taxes established for offsite mitigation projects. Generally, Permittees should anticipate performing maintenance for at least 10 years at a cost of approximately 10% of the offsite mitigation project construction costs.

Privately Maintained

Developer or property owner maintained offsite mitigation projects reduce burden to the Permittees but are more difficult to ensure adequate maintenance over the long-term particularly if responsible parties go bankrupt. In order to ensure O&M of the project, Permittees should consider requiring the responsible party to enter into an escrow agreement with the Permittee. As mentioned in the following section, the developer could be required to pay a set amount equal to some minimum percent (%) of the construction cost of the BMP into the escrow account. This amount could be used by the Permittee in the event that the developer and/or landowner go bankrupt. Permittees could also require the developer to establish the escrow and continue to replenish as it is drawn down for maintenance activities so that the account maintains a minimum level of funds. Additionally, Permittees may have the option of putting a tax lien on the property to pay for O&M or cloud the title. A title with a cloud essentially places a yellow flag on a title and will create cause for closer scrutiny creating difficulty for the property owner when or if they attempt to sell the property.

If O&M responsibility remains with private parties, permittees should consider implementing an education and outreach program that addresses proper BMP maintenance. Education and outreach should address what should be maintained and how often.

Accounting Mechanisms

Funds for offsite mitigation should be collected and deposited into a dedicated fund solely for the purposes of constructing and maintaining offsite mitigation projects. Funds should be restricted so that they cannot be used for other purposes. Options available to Permittees include an escrow account, enterprise funds, and/or a designated revenue account.

Escrow Account

Escrow Accounts are used to hold funds that do not necessarily belong to a given party. An escrow account could be established to provide additional security to the Permittee and/or the developer. The developer could place funds into an escrow account that are dedicated to the construction of an offsite mitigation facility. In this case, the Permittee would benefit from the security that developer has dedicated funds for the project, and are available even if the developer declares bankruptcy during the project. Similarly, the developer would benefit from the security of knowing that the funds are not co-mingled with other city funds. Most likely, an escrow account would only be beneficial if a negotiated funding approach is used in which the developer directly agrees to a certain level of investment. Conversely, if a legally structured approach such as a CFD or impact fee is used, the Permittee would simply place the funds in a dedicated internal account.

Enterprise Funds

Enterprise funds provide goods or services to the public for a fee that makes the entity self-supporting. Government-owned utilities (such as water or wastewater facilities) are examples of enterprise funds. An enterprise fund could be established to collect “fees” from the developer and spend the revenue on construction, O&M of the offsite mitigation funding. There may be advantages to this approach with increased transparency and convenience, especially if multiple municipalities are involved. However, these enterprise fund fees would be regulated by

Proposition 218 as “property-related fees” and would likely be subject to legal and balloting requirements that would severely limit their use.

Designated Revenue Account

Permittees can set up a designated revenue account solely for the purposes of accepting and holding funds from developers received through a in-lieu fee or impact fee programs or CFD taxes. Developers write checks which are then deposited into a designated revenue account where funds are restricted for the use of offsite mitigation projects.

Bridge Funding

If a funding approach is used in which the capital costs are not completely paid up front by the developer, financing will be required. In most cases, for the relatively small capital costs of the proposed facilities, the municipalities should consider self-financing where they pay the initial capital costs and the developer pays it back, plus interest, over time, perhaps through a CFD. If for some reason, self-financing is not available, the municipalities could consider the use of bonds, grants, or a third party approach as a financing tool.

Bonds

Bonds are debt instruments in which an investor loans money to an entity that borrows the funds for a defined period of time at a fixed interest rate. In this case, a Permittee would engage a Financial Advisor and/or Bond Counsel to arrange to sell bonds to raise the capital cost amount needed. The Permittee would then pay back the bond holders at an agreed interest rate and schedule. The Permittee would be paid back, in turn, by a funding mechanism such as a CFD in the amount and on the same schedule as the bond payments. Use of bonds to pay for capital improvements is quite common in California, but there are significant financing costs, which would be borne by the developers, that may make this approach less attractive. A similar approach using Certificates of Participation, (also known as COPs) should also be explored. The significant overhead cost of bonds most likely makes them infeasible given the predicted small need for offsite mitigation facilities.

Grants

State grants are typically awarded through a highly competitive process, often require matching local funds, tend to be focused on capital expenses, are often narrowly focused in terms of scope and services, and can have significant administrative overhead. In addition, most grants are seldom designed to fund the O&M. Nonetheless, the revenue opportunities provided by grants is significant enough that they could be considered a viable approach.

If State grants such as Proposition 84 are pursued, applications should be written to maximize flexibility in use of the funds so the grant award can contribute towards annual expenses. Coordinating with other affected permittees to put forth larger and potentially more competitive grant applications is advised.

Third Party Financing

Occasionally, third party entities have provided financing assistance for infrastructure. These could include private, for profit entities like banks, or not-for-profit entities like environmental organizations. Although the projected need does not seem to warrant the construction of regional

facilities, multi-functional offsite mitigation projects may still be an attractive option for third parties such as municipal water districts.

CONCLUSIONS

A variety of options are available to Permittees for forming the basis of an offsite mitigation program. Each permittee should select an option(s) based on the factors that are of most concern to their community such as projected offsite mitigation need and consideration of burden to permittees and developers. The Developer Builds Offsite Mitigation Project on Public Property, Project-Specific In-Lieu Fee, and CFDs appear to be the most viable options based on need and consideration of burden to permittees and developers. **Table 3** summarizes offsite mitigation program options by responsible party. **Table 4** summarizes the options by several factors including permittee responsibility, permittee risk, developer responsibility, compatibility with projected need, and adaptability to changing need.

Table 3. Summary of Offsite Mitigation Options by Responsibility

Offsite Mitigation Option	Responsibility		
	Construction	Ownership	Maintenance
Developer Builds on Private Property	Developer	Developer/ Property Owner	Developer/ Property Owner
Developer Builds on Public Property	Developer	Permittee	Permittee
Purchase Credits through Private Seller	Private Seller	Private Seller	Private Seller
Reimbursement Agreement	Developer	Permittee	Permittee
Flat In-Lieu Fee	Permittee	Permittee	Permittee
Project Specific In-Lieu Fee	Permittee	Permittee	Permittee
Impact Fee	Permittee	Permittee	Permittee
CFD	Permittee	Permittee	Permittee

Table 4. Summary of Offsite Mitigation Options

Offsite Mitigation Option	Permittee Responsibility	Permittee Risk/Liability	Developer Responsibility*	Compatibility w/ Projected Need	Adaptability to Changing Need
Developer Builds on Private Property	Low. Permittee must verify that BMP fulfills mitigation volume requirements.	Low. Developer identifies site and constructs. May be difficult to guarantee private O&M of project.	High. Developer must identify and construct BMP offsite.	Low. Unlikely that the small mitigation volume supports construction of a new standalone BMP.	High. Developer builds what he/she needs; may be somewhat limited by space availability.
Developer Builds on Public Property	Medium. Permittee must find public property available and suitable for offsite mitigation.	Medium. Developer constructs but likely that Permittee takes over O&M of project; unknown liability if project is not properly constructed.	Medium. Developer must construct.	Medium to High. Developer may be able to implement small BMPs in right-of-way.	High. Developer builds what he/she needs; may be somewhat limited by space availability/ site constraints.
Purchase Credits through Private Seller	Medium. Permittee must verify private projects and keep accurate and up-to-date tracking of credits.	Medium. Risk that market for private seller will not exist or not enough to sustain over long-term.	Low. Developer pays third party; third party takes on liability of mitigation and O&M.	Low. Medium to high mitigation volume is needed in order to sustain.	Low. Realistically, a medium to high mitigation volume is needed in order to sustain.
Reimbursement Agreement	Medium. Permittee must verify private projects and keep accurate and up-to-date tracking of available mitigation volume.	Low. Developer identifies site and constructs. Need to identify mechanism to ensure funding for long-term O&M.	High. Developer must construct BMP offsite and get reimbursed as additional offsite needs come in.	Medium to High. Depends on whether or not the flat in-lieu fee will be used for regional, midsized, or project-specific facilities.	Medium. Program could be altered if growth projections change (e.g., could shift focus from midsized facilities to regional).
Flat Mitigation Agreement/ In-Lieu Fee	High. Permittee must identify, construct and maintain offsite mitigation projects.	Medium to High. Difficult to encompass cost of all scenarios under flat fee. Low guarantee that funds will cover regional facility. Guaranteed O&M since covered by Permittee.	Low. Developer makes payment to Permittee; Permittee takes on O&M.	Medium to High. Depends on whether or not funds will be used for regional, midsized, or project-specific facilities.	Medium. Program could be altered if growth projections change. A change in payment would have to go through Council.
Project Specific Negotiated Mitigation Agreement/ In-Lieu Fee	High. Permittee must identify, construct and maintain offsite mitigation projects.	Low to Medium. Fair share is allocated to developers. Low guarantee that enough developers come in to cover a regional facility. Guaranteed O&M since responsibility of Permittee.	Low. Developer makes payment to Permittee. Permittee takes on O&M.	Medium to High. Depends on whether or not funds will be used for regional, midsized, or project-specific facilities.	Medium. Program could be altered if growth projections change (e.g., could shift focus from midsized facilities to regional).
Impact Fee	Very High. Permittee must identify, construct and maintain offsite mitigation projects and adhere to Govt Code Sec 66000.	Medium to High. Difficult to encompass cost of all scenarios under flat fee. Low guarantee that fee will cover regional facility. Guaranteed O&M since covered by Permittee.	Low. Developer pays Impact fee to Permittee; Permittee takes on O&M.	Medium to High. Depends on whether or not the impact fee will be used for regional, midsized, or project-specific facilities.	Medium. Program could be altered if growth projections change. A change in fee would have to go through Council.
CFD	High. Permittee must set up and construct and maintain project.	Low to Medium. Fair share is allocated to developers. Low guarantee that enough developers come in to cover a regional facility. Guaranteed O&M since covered by CFD taxes.	Low. Developer sets up CFD which pays for capital costs and O&M.	Medium to High. Depends on whether or not the impact fee will be used for regional, midsized, or project-specific facilities.	Low. Once CFD tax rate is establishes, it cannot be easily modified other than annual CPI increase.

*Based on administrative, construction and O&M burden and generalized perceptions of option

A REGIONAL APPROACH TO EVALUATING THE BIOLOGICAL CONDITION OF SOUTHERN CALIFORNIA'S WADEABLE STREAMS

2009-2013: THE FIRST FIVE YEARS OF THE STORMWATER MONITORING COALITION'S REGIONAL MONITORING PROGRAM

OVERVIEW

In 2009, the Southern California Stormwater Monitoring Coalition embarked on an ambitious effort to evaluate the biological condition of 4,300 miles of wadeable streams in the region's coastal watersheds. Over the ensuing five years, the coalition's participating agencies conducted extensive survey and sampling work at more than 500 randomly selected sites encompassing 15 major watersheds in California's South Coast region. Monitoring efforts that had historically been done with minimal coordination were unified around a cohesive, shared vision for the first time, generating high-quality data sets that have painted a powerful picture of regional stream condition. The SMC survey is a regional enhancement of the statewide Perennial Stream Assessment.

The mature riparian plants and biological complexity observed in upper portions of Trabuco Creek in the Santa Ana Mountains reflect a stream that is in good biological condition. 25% of wadeable stream-miles in Southern California were found to be in good condition in the five-year survey.

Caballero Creek, a channelized, algae-filled tributary to the Los Angeles River, reflects severe habitat degradation and impacts of elevated nutrient concentrations. The survey found that both types of stressors were widespread in Southern California streams.

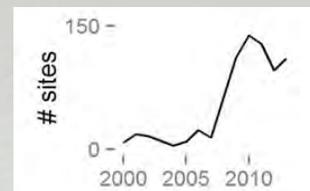

PROGRAM BENEFITS AND IMPACTS

- **Relevant to managers:** Comprehensive data sets inform decisions about priorities and resource allocation, and identify opportunities for causal assessment follow-up studies.
- **Cost-effective:** Each participant realizes approximately 10 times the data value relative to costs.
- **More influential:** Regional collaborations provide more data to inform statewide policymaking, and highlight local concerns.
- **Conversation-altering:** Provides a starting point for developing innovative management strategies that consider and go beyond water chemistry.

KEY FINDINGS

25% of the region's wadeable stream-miles are in good biological condition, including:

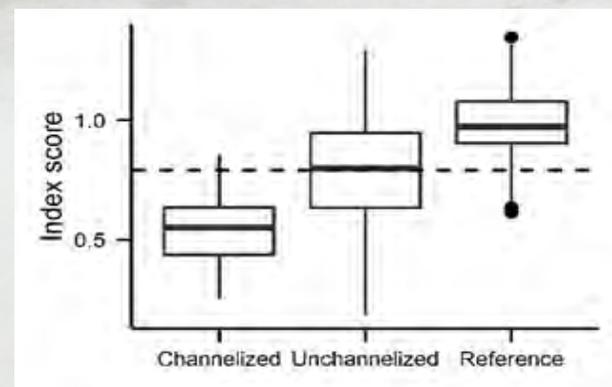

- 60% of stream-miles in open-space
- 9% in agricultural areas
- 2% in urban areas

The Regional Monitoring Program stream survey, which began in 2009, significantly increased the number of stream sites sampled in the region.

HIGH-PRIORITY STRESSORS ON WADEABLE STREAMS

Stressors affecting more than 25% of stream-miles	Stressors affecting 10% to 25% of stream-miles
<ul style="list-style-type: none"> • Nutrients (Nitrogen and Phosphorus) • Physical habitat degradation • Sulfates • Total dissolved solids 	<ul style="list-style-type: none"> • Chloride • Total suspended solids • pH

Index scores based on benthic macroinvertebrates were lower in channelized streams than non-channelized and reference streams; however, high scores for algal indices were observed in channelized streams where water quality was good. These findings provide a basis for regulators and stormwater agencies to discuss management strategies for channelized streams.

FOUR ECOLOGICAL CONDITION INDICATORS

The biological condition of streams was assessed by collecting data for four biological indicators. Each indicator is sensitive to a unique combination of stream stressors, allowing it to provide different types of information about a stream's overall health. Collectively, the four indicators provide comprehensive, direct evidence of a stream's capacity to support aquatic life, a more revealing approach than measuring the chemical concentrations of pollutants.

1 Benthic macro-invertebrates, such as aquatic insects, snails, and worms, respond to changes in habitat or water quality over their lifespans.

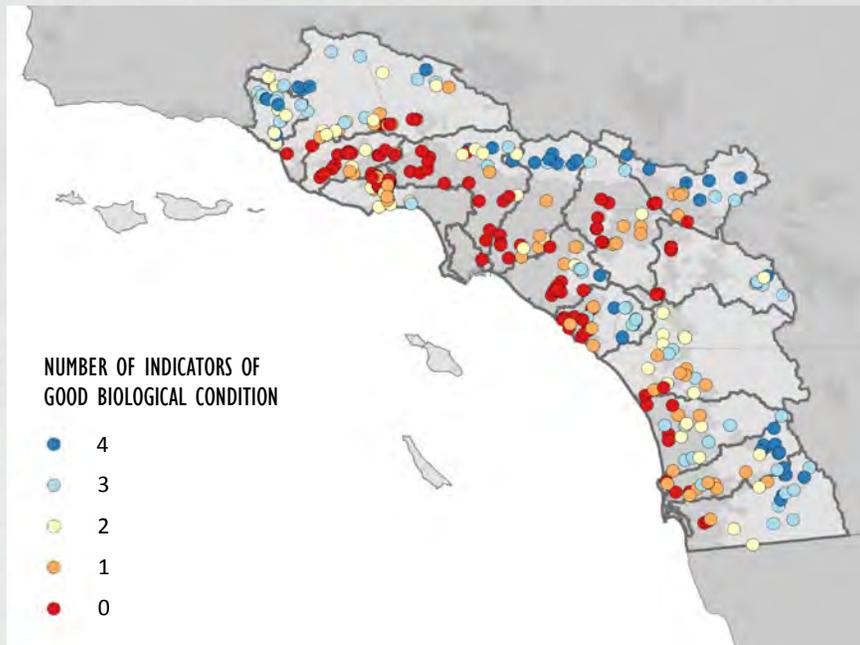

2 Soft algae, such as *Vaucheria*, may form clumps or filaments on submerged rocks. Some species proliferate when nutrients are elevated, while others thrive when nutrients are scarce.

3 Diatoms, such as *Navicula*, respond strongly to changes in water chemistry and sedimentation.

4 Riparian habitats, which support both terrestrial and in-stream wildlife, may be degraded by habitat alteration, upstream discharges, and hydrologic modification.

At the 500+ randomly selected sampling sites in the stream survey, anywhere from 0 to all 4 biological indicators indicated that a site was in good biological condition. The four indicators – benthic macroinvertebrates, diatoms, soft algae, and riparian habitat condition – collectively were used to assess a site's biological condition.

WATERSHEDS WITH MANY STREAMS IN GOOD CONDITION

- Ventura River
- Upper Santa Ana River
- Tijuana + Sweetwater + Otay Rivers

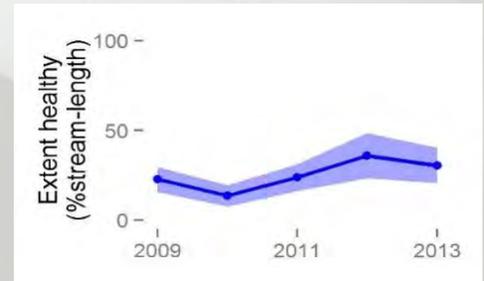

WATERSHEDS WITH FEW STREAMS IN GOOD CONDITION

- Calleguas Creek
- Lower Santa Ana River
- San Dieguito River + Carlsbad Hydrologic Unit

NO APPARENT TRENDS

Although there was some year-over-year variability, the survey did not find a change in the health of the streams over the five-year sampling period, from 2009 to 2013.

Urban streams tended to be in consistently poor biological condition, whereas open-space and agricultural streams tended to experience greater year-to-year variability.

The portion of healthy stream-miles fluctuated over the five-year sampling period, but overall showed no clear trends in either direction. The blue shading represents the 95% confidence interval.

A NEW SURVEY UNDERWAY

The success of the SMC's Regional Monitoring Program has paved the way for a second round of the program, which began in spring 2015. The first five-year survey will serve as a baseline for detecting trends over time.

The second cycle includes nonperennial streams, a critical habitat that makes up more than half of the region's stream-miles, and will seek to clarify the linkage between stressors and biotic integrity.

ACKNOWLEDGEMENTS

This survey was jointly funded by the California State Water Resources Control Board, the Stormwater Monitoring Coalition, and the SMC member agencies. The authors thank the following labs, scientists, and agencies for providing data for this project: the California Surface Water Ambient Monitoring Program; Ventura Countywide Stormwater Quality Management Program; Los Angeles County Flood Control District; Council for Watershed Health; Orange County Public Works; San Bernardino County Stormwater Program; Riverside County Flood Control and Water Conservation District; San Diego County Public Works; San Francisco Estuary Institute; California Regional Water Quality Control Boards of the Los Angeles, Santa Ana, and San Diego Regions; State Water Resources Control Board; and California Department of Fish and Wildlife Aquatic Bioassessment Laboratory; as well as, Aquatic Bioassay and Consulting Laboratories; AMEC Environment & Infrastructure; Nautilus Environmental; Weston Solutions, Inc.; Drs. Dessie Underwood and Richard Gossett at California State University, Long Beach; EcoAnalysts, Inc.; Dr. Patrick Kociolek at University of Colorado, Boulder; Drs. Robert Sheath and Rosalina Hristova at California State University, San Marcos; Moss Landing Marine Laboratories; CRG Marine Laboratories; and Edward S. Babcock Laboratories, Inc. Additional technical support was provided by the Los Angeles County Sanitation District, the City of San Diego, and the Geographic Information Center at California State University, Chico.

EXECUTIVE SUMMARY

Streams are important natural resources in the South Coast of California, a region that extends from Ventura to San Diego counties. Competing needs for aquatic resources are intense and growing. Assessing the biological condition of these streams has been the focus of considerable monitoring activity. However, until 2009 these efforts were minimally coordinated and provided only limited information about the health of streams in the region, as a result of an emphasis on end-of-watershed monitoring. The Stormwater Monitoring Coalition (SMC) regional perennial stream survey was created in response to the need for a more holistic and coordinated approach. This report provides the results of a five-year probability-based bioassessment of southern California's perennial wadeable streams and represents one of the most comprehensive assessments of stream conditions in the United States.

The five-year survey was designed to answer key questions that are essential to watershed management:

- 1) What is the biological condition of perennial streams in the region?
- 2) What stressors are associated with poor condition?
- 3) Are conditions changing over time?

The Stormwater Monitoring Coalition has greatly increased the number of sites sampled in southern California.

Answering these questions at the regional scale provides resource managers with the ability to contextualize their programs and improve understanding of the effectiveness of management actions, prioritization of streams most in need of protection, and identification of stressors that are likely to pose the greatest risk to stream health.

Prior to the initiation of the SMC perennial stream survey, bioassessment efforts in southern California had a limited ability to answer any of these questions. Lead monitoring agencies worked

with little coordination, typically addressing site-specific problems with sometimes incomparable methodologies and rarely sharing data. Targeted monitoring mandated by permits did not provide the regional context needed to inform management decisions. Earlier probabilistic sampling efforts in southern California were limited (rarely more than a handful of sites per year), and were conducted as a small part of a statewide or national assessment.

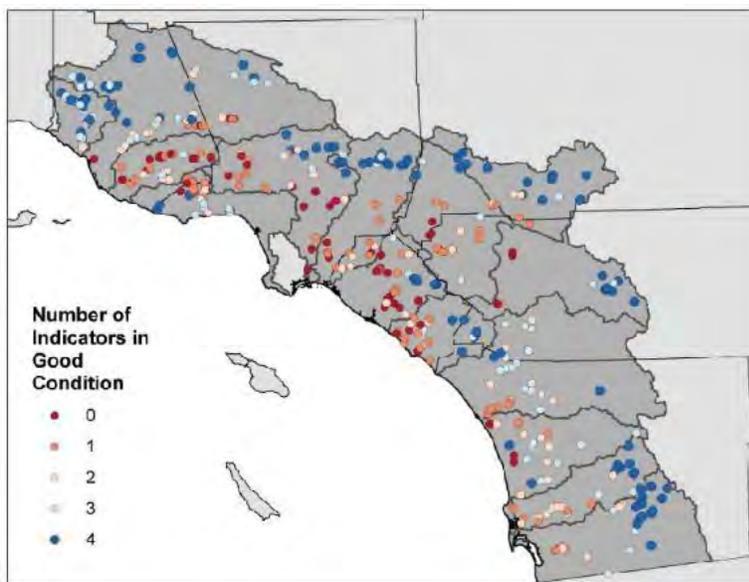

Since the initiation of the SMC perennial stream survey in 2009, stormwater agencies have been able to coordinate their monitoring efforts with regulatory agencies, reallocate resources, and

generate the needed data in a cost-neutral way, while simultaneously allowing regulated agencies to fulfill their permit obligations. This survey serves as the regional component of the statewide Perennial Stream Assessment, allowing both the SMC and the State Water Resources Control Board to leverage resources and support each other's surveys.

To answer key management questions, over 500 sites were sampled for four key indicators of biological condition: benthic macroinvertebrates, diatoms, soft algae, and riparian wetlands. These indicators were used to assess the biological health of over 7000 km of streams. In addition, water chemistry, water column toxicity, and physical habitat were examined in order to identify stressors affecting biological conditions in the region. Furthermore, because the survey spanned five years, initial estimates of regional trends are now possible.

Key Findings

Biologically healthy perennial streams are a scarce resource, comprising only 25% of perennial wadeable stream-miles in the region. Based on four biological indicators (i.e., benthic macroinvertebrates, diatoms, soft algae, and riparian wetlands), perennial streams in good biological condition (i.e., scores above the 10th percentile of reference sites) were largely confined to undeveloped portions of watersheds; most indicators identified slightly better conditions at agricultural streams relative to urban streams. Ventura, Santa Clara, Upper Santa Ana, and Southern San Diego watersheds were in better condition than other watersheds for most indicators, whereas perennial streams in poor condition (i.e., scores below the 10th percentile of reference sites) were most extensive in Calleguas, Los Angeles, San Gabriel, and Lower and Middle Santa Ana watersheds.

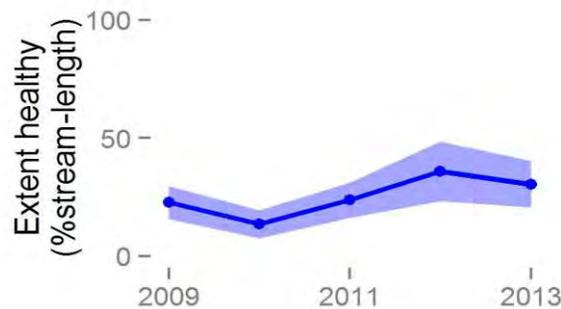

Perennial stream condition was evaluated with four biological indicators: benthic macroinvertebrates, diatoms, soft algae, and riparian condition. In general, these components of the stream community rarely indicated good health in developed portions of watersheds.

Nutrients, sulfates, and habitat degradation were extensive, high-risk stressors associated with poor biological condition. Future investigations should consider these possible candidate stressors as potential causes of poor biological condition. In contrast, metals, pyrethroids, and toxicity were either rarely above threshold or weakly associated with biological condition.

A large extent of the South Coast region was at risk from physical habitat degradation, elevated nutrients, and major ions. Pyrethroids and metals were either weakly or rarely associated with poor health.

Very high priority (Affects more than 25% of region)	High priority (Affects more than 10% of region)	Moderate or low priority (Limited extent or low risk)
Nitrogen	Chloride	Pyrethroids
Phosphorus	Suspended solids	Metals
Physical habitat	pH	Biomass
Sulfates		Toxicity
Dissolved solids		

No changes in biological condition were detected. Although mean condition estimates fluctuated from year to year, conditions in 2013 were similar to those observed in 2009; fluctuations were primarily driven by variability in undeveloped streams, as urban streams were consistently in poor condition, varying little from year to year. At no time during the survey were more than 35% or less than 14% of streams estimated to be intact for all indicators. Moving forward, the ability to detect trends could be improved by minor changes to the study design, such as revisiting sites over several years and by extending the survey for additional years.

Extent of perennial streams in good biological condition for all four indicators (benthic macroinvertebrates, diatoms, soft algae, and riparian condition) fluctuated from year to year, but was always limited to less than 35% of perennial stream-miles in the region. The band indicates the 95% confidence interval.

How can this survey support management decisions?

Evaluate steps to protect healthy streams and improve unhealthy streams. Given the small extent of healthy perennial stream-miles in the southern California, protecting such streams may be a priority for resource managers. Additionally, the relatively large extent of stream-miles in poor condition suggests that managers will need to prioritize actions to address stressors affecting unhealthy streams. Prioritization should focus on likelihood of success, achievability of objectives, breadth of impact, and costs associated with management activities, as well as local objectives and needs for each waterbody. Although most of the actions required will be site-specific, a regionally coordinated approach will aid in priority ranking and enable leveraging of efforts across sites or watersheds.

Use regional context in site-specific evaluations. The primary application of survey data is to provide context in evaluating site-specific questions. Comparing the condition of a specific site to conditions at sites with similar land use within the region may provide more useful benchmarks for management objectives than comparison to reference sites, which may not provide an achievable management objective.

Use survey data in causal assessments to identify candidate stressors. Because of the breadth of information collected at each site, the comparability of methods used, and the diversity of sites sampled, data from this survey are well suited to causal assessment applications. With some investment in tool development, regional watershed managers will be able to overcome the data limitations (such as difficulties in identifying comparison sites with information on stressors) that often hinder effective causal assessments.

Recommendations for future monitoring

Although this survey successfully produced preliminary answers to key questions, important knowledge gaps remain. Continuing the survey with modifications will address these gaps.

Include stream types that were previously excluded from the survey. The chief limitation of this survey is that it was restricted to perennial, wadeable streams, 2nd order and higher. The condition of nonperennial and headwater streams represents the largest gap in our regional assessment. Perennial streams account for only 25% of stream-miles in the region as a whole, and as little as 5% in certain watersheds; this variation is caused by both natural factors (such as climate) and land use. Because

perennial and higher-order streams are more abundant in developed regions, it is likely that the surveyed portion of the region is in worse condition than the region as a whole. Expanding the survey to include assessment of nonperennial streams (approximately 59% of stream-miles in the region), and exploring ways to map them will help fill these knowledge gaps. Existing

assessment tools may be appropriate to assess condition of nonperennial streams, and new tools should be developed as needed.

Improve trend detection through site revisits. Probabilistic sites that are revisited for several years can be used to estimate the extent of improving, degrading, or stable streams in the region. Additionally, management practices associated with changes in conditions can be identified.

Use survey data and special studies to support causal assessments and investigate high-priority stressors. Stressor prioritizations are strictly associative and cannot identify with certainty causal relationships between stressors and biological condition. In some cases, stressors that were identified as high priority (e.g., nutrients) might not directly affect biological condition. Instead, the high risk may reflect a correlation with an unmeasured stressor. The frequent co-occurrence of multiple stressors can make it difficult to disentangle the relationships between individual stressors and biological condition. The SMC can address these limitations in several ways:

- Analyze existing data to explore the diagnostic potential of biological indicators to identify specific stressors.
- Enhance the stream survey with new indicators related to habitat degradation (e.g., hydromodification indicators) or nutrient enrichment (e.g., continuous water quality loggers, algae biomass), or other stressors of emerging concern (e.g., sediment pyrethroids).
- Conduct special studies to distinguish biological constraints imposed by habitat degradation, channel engineering, water chemistry, and natural factors.

SURVEY OVERVIEW

This survey provides the best estimate of the extent of perennial (e.g., Big Tujunga Creek, upper photo) and nonperennial streams (e.g., San Juan Creek, lower photo) in the South Coast region.

Introduction

Southern California's coastal watersheds contain important aquatic resources that support a variety of ecological functions and environmental values. Comprising over 7,000 stream-kilometers, both humans and wildlife depend on these watersheds for habitat, drinking water, agriculture, and industrial uses. In order to assess the health of streams in these watersheds, the Stormwater Monitoring Coalition (SMC), a coalition of multiple state, federal, and local agencies, initiated a regional monitoring program in 2009. Using multiple indicators of ecological health, including benthic macroinvertebrates, benthic algae, riparian wetland condition, water chemistry, water column toxicity, and physical habitat, the SMC has led the first comprehensive assessment of southern California's watersheds based on a probabilistic survey design. Through the re-allocation of permit-required monitoring efforts, the SMC has developed a cooperative sampling program that is efficient and cost-effective for participants. This report represents a summary of data collected in the first five years of the SMC's stream survey. Data from previous surveys, such as the Environmental Protection Agency (EPA) Environmental Monitoring and Assessment Program (EMAP) and California's Perennial Stream Assessment (PSA), are included as well.

The SMC monitoring program was designed to address three main questions:

- 1) What is the biological condition of perennial streams in the region?
- 2) What stressors are associated with poor condition?
- 3) Are conditions changing over time?

The first question is addressed by estimating the extent of biologically intact streams, as determined by key biological indicators. The second question is addressed by estimating the extent of streams with stressors above key thresholds, and by associating stress levels with biological indicators through correlation and relative risk analyses (Van Sickle *et al.* 2006). The third question is addressed by comparing condition across years of the survey.

Regional assessments provide critical information to complement site-specific monitoring at sites of interest. Regional surveys that use a probabilistic design provide statistically valid and unbiased assessments of large geographic areas (Gibson *et al.* 1996). Crucially, regional assessments provide context to site-specific problems and allow sites to be prioritized for protection or restoration (Barbour *et al.* 1996). Furthermore, regional assessments provide a comprehensive perspective on reference conditions (Reynoldson *et al.* 1997). Although regional programs do not replace the need for monitoring at sites of interest (such as below discharges or within sensitive wildlife areas), the context provided by a regional assessment is essential for effective watershed management (Barbour *et al.* 1996, Gibson *et al.* 1996).

Methods

Study Area

Coastal southern California (i.e., the South Coast) is a semi-arid region with a Mediterranean climate, which experiences nearly all of its precipitation as rainfall during winter months. Lower elevations are characterized by chaparral, oak woodlands, grasslands, and coastal sage scrub. The region is bordered by the Transverse Ranges to the North, and the Peninsular Ranges to the East, and continues to the Mexican border to the South. Both Transverse and Peninsular ranges contain peaks that exceed 10,000 feet and regularly experience snow, although contributions to stream flow are limited. Much of the higher elevations are undeveloped and remain protected in a network of national, state, and county parks and forests. The lower elevations have been largely urbanized or converted to agriculture. Wildfires and drought are frequent in the region, with extensive fires occurring in 2007, 2009, and 2013 throughout much of the area. By area, the overall region is 59% undeveloped open space, 28% urban, and 13% agricultural (National Oceanic and Atmospheric Administration (NOAA) 2001).

Survey Design

The target population of the survey was defined as perennial, wadeable second-order and higher streams located in the six southern California counties draining into the Southern California Bight. The study area was divided into fifteen management units (hereafter referred to as watersheds) based on a combination of hydrologic and political boundaries (Table S-1, Figure S-1). The National Hydrography Dataset Plus stream network (NHD Plus; US Geological Survey and US Environmental Protection Agency 2005) was used as the sample frame. Stream segments in the NHD Plus typically represent lengths of streams between two confluences, although particularly long reaches are often split into shorter lengths. In order to assign land-use to each segment of the NHD Plus frame, a 500-m buffer was drawn around each stream segment and overlain in a GIS onto a landcover layer (NOAA 2001). If the buffer was more than 75% natural or open land, the segment was considered open space; if not, it was considered urban or agricultural, depending on which land use was relatively more dominant. Very short segments were occasionally hand corrected if the buffers were too small to adequately capture the adjacent land use; these corrections were most typically used for segments representing individual channels in complex braided systems, such as the mainstem of the Santa Clara River.

The study employed the “master list” approach to integrate sampling efforts by multiple agencies and to facilitate collaboration with other monitoring programs (Larsen *et al.* 2008). A master list was generated, containing over 50,000 sites randomly distributed across the entire stream network using a spatially balanced generalized random-tessellation design (Stevens and Olsen 2004). Sites were then assigned to a watershed using a geographic information system (GIS). Sites were attributed with Strahler stream order from the NHD Plus dataset, and with land use based on the designation of the stream segment, as described above. Sites were then attributed with watershed, stream order, and land-use of the corresponding stream segment of the sample

frame. First order streams were excluded from the survey, because these sites typically have a higher rejection rate based on nonperenniality or inaccessibility in mountainous regions. A target sample of 30 sites was selected from each watershed, with heavier representation in relatively uncommon strata (e.g., agricultural streams) to improve balance among the sampled stream types. Large oversamples (ranging from 5x to 20x) were selected as well because of high rejection rates in certain strata. Sites in the sample draw and oversamples were distributed to field crews for evaluation for sampling suitability.

Sites were evaluated for sampling using both desktop and field reconnaissance. Field crews attempted to locate a reach suitable for sampling within 300 m of the target coordinates. Sites with no nearby suitable reaches were rejected for sampling. Reasons for rejection included nonperenniality (see box below), inaccessibility (defined as sites that cannot be safely reached and sampled within one day), refusal or lack of response from landowners, map errors (e.g., no channel near the target coordinates), nonwadeability (i.e., >1 m deep for at least 50% of the reach) and inappropriate waterbody types (e.g., tidally influenced, impounded, etc.). Sites with temporary accessibility or permission issues (e.g., road closures, late responses from landowners) were re-evaluated for sampling in subsequent years.

Defining and Determining Perennial Streams

Perennial streams were defined as those with continuous flow that lasts until the end of the hydrologic year (i.e., September 30) in most years. Determining if a site met these criteria required that field crews find the best available data, including stream gauges, field indicators, historical imagery, consultation with local experts, and best professional judgment. Although all reasonable efforts were made to confirm the perenniality of the sampled sites, it is likely that some of them do not meet the survey's criteria for perennial streams during the years of the study. Therefore, the survey reflects the condition of a mixture in unknown proportions of perennial and long-lasting nonperennial streams. Development of an objective tool to characterize hydrologic regimes remains a priority research area for the SMC.

Sampling Methods

Biological Indicators

Benthic Macroinvertebrates

Benthic macroinvertebrates were collected using protocols described by Ode (2007). At each transect established for physical habitat sampling, a sample was collected using a D-frame kicknet at 25, 50, or 75% of the stream width. A total of 11 ft² (~1.0 m²) of streambed was sampled. This method was identical to the Reach-Wide Benthos method used by EMAP (Peck *et al.* 2006). However, in low-gradient streams (i.e., gradient <1%), sampling locations were adjusted to 0, 50, and 100% of the stream width, because traditional sampling methods fail to capture sufficient organisms for bioassessment indices in these types of streams (Mazor *et al.* 2010). Benthic macroinvertebrates were collected and preserved in 95% ethanol (final

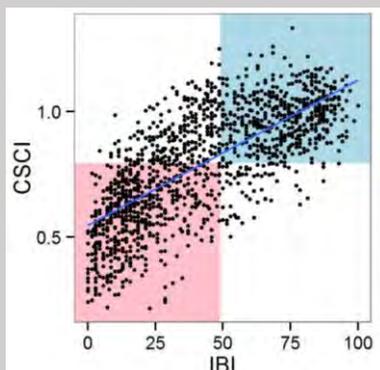

concentration 70%), and sent to one of five labs for identification. At all labs, a target number of at least 600 organisms were removed from each sample and identified to the highest taxonomic resolution that can be consistently achieved (i.e., SAFIT Level 2 in Richards and Rogers 2011); in general, most taxa were identified to species and Chironomidae (i.e., midges) were identified to genus. Benthic macroinvertebrate data was used to calculate the California Stream Condition Index (CSCI; Mazor et al. In Press). Samples from streams in reference condition are expected to have a mean CSCI score of 1.

CSCI vs. IBI

Like the Southern and Central California Index of Biotic Integrity (IBI), the CSCI was designed to measure the biological condition of streams, as indicated by benthic macroinvertebrate assemblage structure. The CSCI characterizes benthic macroinvertebrate assemblage structure in two ways: 1) As the ratio of observed-to-expected taxa (an O/E index), and 2) as a multi-metric index (MMI), where biological metrics related to important ecological attributes (e.g., number of sensitive taxa) are compared with expected values. Both components are compared to expectations that vary from site to site, and these expectations are derived from reference sites in similar environmental settings.

The CSCI was developed specifically to address some of the shortcomings of traditional indices like the IBI and provides a better measure of stream health than its predecessor because of two key features. First, the CSCI was developed with a much larger, more representative data set. For example, 473 reference sites were used to calibrate the CSCI (including 27 from lower elevation South Coast xeric sites), versus 88 for the IBI (of which only 9 were from South Coast xeric regions). More importantly, the CSCI sets biological benchmarks for a site based on its environmental setting (determined by environmental factors, like climate, geology, watershed area, and elevation) whereas the IBI makes minimal adjustments for natural environmental influences on stream communities.

Overall, the CSCI and IBI have similar performance, and samples that score high for one index usually score high for the other (Pearson's $r^2 = 0.54$). In general, the CSCI is more accurate, and is less likely than the IBI to give false indications of nonreference condition. However, it is also less sensitive, and is less likely to indicate nonreference conditions at severely stressed sites. If a threshold based on the 10th percentile of reference sites is applied to both indices (i.e., 0.79 for the CSCI and 49 for the IBI), approximately one-third of streams below the IBI threshold would be above the CSCI threshold; in contrast, only 2% of streams below the CSCI threshold would be above the IBI threshold.

Correlation between IBI and CSCI scores for sites in southern California. The pink area indicates sites where both indices suggest likely altered biological condition (i.e., Class 3 and 4), and the blue area indicates sites where both indices suggest intact or possibly altered biological condition (i.e., Class 1 and 2). The blue line represents a linear regression between the two indices.

Benthic Algae

Benthic algae samples were collected using the protocols of Fetscher *et al.* (2009), approximately 1 foot upstream of each location where benthic macroinvertebrates were collected. Diatom samples were preserved in formalin, and soft algae samples were preserved in glutaraldehyde. Unpreserved, qualitative soft algae samples were also collected to produce fruiting bodies that facilitate identification of soft algae species. Benthic algae samples were identified to the best taxonomic resolution possible, which was typically species. Benthic algae was assessed using two indices from Fetscher *et al.* (2014): a soft algae index (S2), and a diatom index (D18). Calculations were completed using custom scripts in the statistical software R. Samples from streams in reference condition are expected to have a mean D18 score of 79 and a mean S2 score of 69. Although these indices are not “predictive” like the CSCI score, little bias from natural gradients was evident at reference sites (Fetscher *et al.* 2014).

Riparian Wetlands

Riparian wetland condition was assessed using the California Rapid Assessment Method (CRAM; Collins *et al.* 2008). Briefly, the CRAM method assesses four attributes of wetland condition: buffer and landscape, hydrologic connectivity, physical structure, and biotic structure. Each of these attributes is comprised of a number of metrics and submetrics that are evaluated in the field for a prescribed assessment area. Streams in reference condition are expected to have a mean CRAM score of 84.

Water Chemistry

Field crews measured pH, specific conductance, dissolved oxygen, salinity, and alkalinity at each site visit using digital field sensors (or by collecting samples for lab analyses, where appropriate). In addition, samples of stream water were collected for measurements of 36 different analytes, including: total suspended solids, total hardness (as CaCO₃), silica, sulfate and other major ions, nutrients, dissolved and total metals, and pyrethroid pesticides. Analytical methods and quality assurance protocols are described in SWAMP QAT (2008).

Toxicity

At each site, ~4 L of water were collected for toxicity assays, primarily using the water flea *Ceriodaphnia dubia*. Six to eight day exposures to undiluted field-collected stream water were conducted, and both survival (acute toxicity as percent mortality) and reproduction (chronic toxicity as young per female) endpoints were recorded. In samples with specific conductivity ≥ 2500 $\mu\text{S}/\text{cm}$, a 10-day survival assay using the amphipod *Hyaella azteca* was used instead, with no reproductive endpoint (USEPA 2002, SWAMP QAT 2008).

Physical Habitat

At each site, physical habitat was evaluated using a physical habitat assessment as specified in Ode (2007) and Fetscher *et al.* (2009), which were adapted from EMAP (Peck *et al.* 2006). Briefly, a 150-m reach (250-m for streams over 10 m wide) was divided into 11 equidistant

transects, with 10 inter-transects located halfway between them. At each transect, the following parameters were measured: bank dimensions, wetted width, water depth in five locations, substrate size, cobble embeddedness, bank stability, microalgae thickness, presence of coarse particulate organic matter, presence of attached or unattached macroalgae, presence of macrophytes, riparian vegetation, instream habitat complexity, canopy cover using a densiometer, human influence, and flow habitats. A subset of these variables were measured at each inter-transect as well. The slope of the water surface was measured across the entire reach at each site. Metrics based on physical habitat data were calculated using custom scripts in R, based on those presented in Kaufmann *et al.* (1999).

Challenges in Assessing Physical Habitat

Although many studies point to a crucial role for physical habitat in supporting healthy streams, assessing the condition of physical habitat remains a challenge for bioassessments. There are four parts to this challenge: 1) measuring the right variables, 2) calculating meaningful metrics from these variables, 3) comparing these metrics to benchmarks that are appropriate for the environmental setting of a site, and 4) ensuring that the metrics are comprehensive enough to characterize important aspects of habitat degradation. To some extent, the first two problems have been addressed. The protocol developed by SWAMP, based on methods developed by the EPA (Peck *et al.* 2006), encompasses over 1000 individual measurements per site, and these measurements are converted into more than 150 metrics that characterize the physical habitat, again based on earlier efforts of the EPA (Kaufmann *et al.* 1999). However, most of these metrics vary widely among reference sites, based on environmental factors like climate and watershed size. Predictive models to set reference-based expectations for physical habitat metrics are in development, but are not yet available. Once such models are developed, a remaining challenge will be to select which metrics (and in which combinations) are most useful in characterizing the overall condition of the physical habitat of a site.

Landscape Variables

Landscape variables were calculated for three purposes: CSCI calculation (see Mazor *et al.* In review), reference site screening (see Ode *et al.* In review), and biological relationships. Using a GIS, watersheds were delineated for each site from 30-m digital elevation models (USGS 1999), and visually corrected to reflect local conditions. For sites draining ambiguous watersheds with minimal topography, delineations were modified using CALWATER boundaries (California Department of Forestry and Fire Protection 2004) or by consulting local experts. Watersheds were clipped at 5 km and 1 km to evaluate local conditions, creating a total of three scales (abbreviated as WS, 5k, and 1k). A fourth scale (i.e., point), based only on the site location, was used to calculate distance-based metrics. These delineations were then used to calculate metrics from source layers relating to landcover (NOAA 2001), transportation (CDFG custom roads layer, P. Ode, unpublished data), geology (J. Olson and C. Hawkins, unpublished data), and hydrology (National Inventory of Dams and NHD Plus). For sites sampled in 2013, only variables related to the CSCI were calculated.

Summary of Data from Other Surveys

Data from other surveys were included in this report, where possible. In order to be included, these surveys had to meet the several criteria: 1) benthic macroinvertebrates were collected using similar protocols (e.g., EMAP), 2) benthic macroinvertebrates were identified to equivalent taxonomic resolution, 3) survey design documentation (including stratifications) and site evaluation data were available, and 4) compatible sample frames were used for survey design (specifically, the NHD Plus or its predecessor RF3). These surveys are summarized in Table S-2. Note that some sites, although selected for sampling for a probabilistic survey, were revisited under other programs (such as reference sampling, fire studies, or other targeted designs), and these data were included in the current assessment as well. With few exceptions, limited data types (generally, benthic macroinvertebrates and physical habitat) were collected for these surveys.

Climate Data

Monthly rainfalls for stations throughout the region were downloaded from The National Oceanic and Atmospheric Administration's California and Nevada River Forecast Center (www.cnrfc.noaa.gov/rainfall_data.php). Annual totals were then calculated and plotted to evaluate the conditions during the study period relative to longer term trends. Three representative stations were selected for plotting (i.e., downtown Los Angeles, Big Bear Lake, and Lindbergh Field).

Data Analysis

Weighted Magnitudes and Extent Estimates

Adjusted sample weights were calculated for each site. Because multiple surveys with different designs were included in analysis, weights needed to be recalculated for each site. Stratification approaches from all surveys were combined to create "cross-strata" in which all evaluated sites have an equal probability of being sampled. Adjusted weights were recalculated as the total stream length within each strata, divided by the number of sites evaluated in that stratum. Strata with no evaluations were excluded from analysis. Because these strata comprised less than 2% of the total stream length, these exclusions are unlikely to affect condition estimates. These weights were used to estimate distribution points for selected variables and extents (e.g., % of stream-length in classes of interest) using the Horvitz-Thompson estimator (Horvitz-Thompson 1952). These estimates were calculated for reporting units of interest, including watersheds, land use classes, and (for trend estimates) years. Confidence intervals (CIs) were based on local neighborhood variance estimators (Stevens and Olsen 2004). All calculations were conducted using the *spsurvey* package (Kincaid and Olsen 2013) in R version 3.0.3 (R Core Team 2012).

Extent Estimates

When surveys use a probabilistic design, the data they produce can be used to make inferences about the region as a whole, and not just about sampled sites. Therefore, statements about the extent of perennial wadeable streams, or about the average CSCI score in a watershed can be made. Probabilistic surveys provide context about ambient condition, which can be used to compare against sites of interest.

The key benefit of a probabilistic survey is its ability to estimate the true extent of a resource of interest, such as perennial, wadeable streams. Sites sampled under a targeted design provide valuable information about local conditions, but cannot be used to estimate the condition of the region as a whole. Because targeted studies are typically designed to assess known impacts (e.g., downstream of discharges), the sites may be in worse condition than the average site in the region; therefore, estimates of regional condition from targeted sites may be biased.

When sites are sampled according to a probabilistic design, measurements represent not just local conditions, but also reflect conditions of a much larger population. The condition of each probabilistic site therefore contributes to condition estimates of the region as a whole. The weight (i.e., the contribution to regional estimates) of each site varies; sites in large, sparsely sampled regions (e.g., open streams) make a larger contribution to regional estimates than sites in small or densely sampled regions (e.g., agricultural streams).

Results

A total of 760 probabilistic sites were sampled in the South Coast region, of which 515 were sampled by the SMC or affiliated programs (Table S-2). To attain this sample size, 4330 unique sites were evaluated, yielding a rejection rate of 82%. The most common cause for rejecting a site was nonperenniality (75% of rejected sites), followed by physical barriers (9% of rejected sites). Determinations of nonperenniality were made during both office and field reconnaissance. Other causes for rejection (e.g., map errors, inappropriate waterbody types, nonwadeability) were infrequently encountered ($\leq 5\%$ of rejected sites; Table S-3; Figure S-2).

Analysis of rejected sites indicated large differences in the extent of perennial streams by watershed and land use. For example, perennial streams made up 53% of stream-miles in the Los Angeles watershed, but only 6% of the San Jacinto watershed (median watershed extent: 26%). Land-use was strongly associated with perenniality, as 35% of urban stream-length, but 12% of agricultural stream-length and 16% of open stream-length were perennial (Figures S-2, S-3, S-4).

Overall, the survey occurred in a drier than normal period. Rainfall during 2011 was slightly above average, although most other years were well below normal. Notably, the survey occurred shortly after one of the driest years on record (i.e., 2007), when even the rainier weather stations (e.g., Big Bear Lake) reported extremely low precipitation (Figure S-5).

Discussion

Perennial wadeable streams are a small component of the region, and protecting this limited resource may be a high priority for watershed managers, particularly because of their importance to a variety of beneficial uses (such as fisheries, wildlife, and swimming). At the same time, the need to expand attention to nonperennial streams is apparent: A comprehensive assessment of the coastal watersheds of southern California should not exclude the large extent of nonperennial streams. Ongoing research in the region addresses the question of whether the condition indices used in this survey are valid in nonperennial streams. However, it is likely that assessment tools currently available to watershed managers are adequate to include at least some portion of nonperennial streams in future surveys.

The observed extents of perennial streams in urban and agricultural areas are probably elevated by imported water sources (either as wastewater effluent or as runoff). Because nonperennial streams are so extensive in undeveloped areas, it is likely that this survey excludes many of the healthiest, least disturbed streams in the region. Therefore, although this survey provides an unbiased assessment of the perennial portion of southern California streams, extrapolation to the nonperennial portion may lead to incorrect conclusions about the health of the region as a whole.

Climatic trends may have also influenced the extent and location of perennial streams. Frequently, field crews were unable to sample reaches that were historically perennial, suggesting that long-term drought or changes in water management may have converted some perennial streams to nonperennial. The variability of flow regimes in southern California streams has been documented in special studies commissioned by the SMC (e.g., Mazor *et al.* 2014), and this variability underscores the need for a flexible approach towards characterizing stream hydrology.

The widespread conversion of streams from nonperennial to perennial (and vice versa) presents a question about setting appropriate ecological objectives. Should a converted stream be compared to perennial reference streams? Or is it more appropriate to compare them to their historical conditions? This survey used the former approach, although in certain applications, such as setting restoration objectives, different goals may be appropriate.

However objectives are set for streams with altered hydrology, managing flows may be an important tool in supporting their ecological health. The causes of elevated water flows were not investigated in this survey. In major tributaries and mainstems of large rivers, elevated flows may be driven by effluent from treatment plants managed by sanitation districts. In smaller streams, runoff may be an important driver, where flood control agencies manage stream flows. Diversions and groundwater extraction are particularly important in streams in agricultural areas. Therefore, if flow regime management needs to change to support ecological health, coordination among several agencies working under different permits may be required.

Table S-1. Characteristics of each watershed.

Watersheds	Stream Order	Area (km ²)	Total Stream Length (km)	Land Use (%)		
				Open	Agricultural	Urban
Ventura	6	642	236	68	15	17

QUESTION 1: WHAT IS THE BIOLOGICAL CONDITION OF PERENNIAL STREAMS IN THE SOUTH COAST REGION?

Healthy perennial streams, like this site on the North Fork of the San Jacinto River, are a scarce resource in the South Coast region.

Introduction

Surveys of ambient biological condition provide essential context for watershed management. At larger geographic scales, ambient surveys allow watershed managers to identify regional priorities. At local scales, ambient surveys allow managers to compare sites of interest to typical ranges in the region. This context informs decisions about which sites need protection or rehabilitation.

The biological condition of perennial streams was assessed by sampling four key biological indicators (i.e., benthic macroinvertebrates, diatoms, soft algae, and CRAM) at sites throughout the region, and comparing them to thresholds benchmarked to the distribution of scores at reference sites. These biological indicators provide a direct measurement of ecological health, and are an effective tool to determine if streams are supporting aquatic life or other beneficial uses. Additionally, their ability to integrate multiple stressors across both time and space make them a superior measure of biological condition to direct measures of stressors.

Methods

Data Collection

Data were collected as described in the Survey Overview.

Data Aggregation

Where multiple biological samples were collected at a single site within a year, data were aggregated as the maximum value within a site (with the assumption that index scores may be spuriously low, but not spuriously high). Multi-year mean values for each site were then calculated from these aggregated values if sites were revisited in multiple years. Missing values were ignored for all relevant analyses, where appropriate.

Thresholds

Biological indicators were compared to the 30th, 10th, and 1st percentile of reference sites (Table 1-1); these percentiles correspond to different probabilities that a score is from a site in reference condition. This approach creates four biological condition-classes that may be interpreted as indicating a stream's biology is likely intact (Class 1), possibly altered (Class 2), likely altered (Class 3), and very likely altered (Class 4). These percentiles were selected to reflect a range of conditions. Because this approach is consistent across indicators, it is possible to compare results from one index to another. Means and standard deviations were from published sources (CSCI: Mazor *et al.* In review; algae IBIs: Fetscher *et al.* 2014) or unpublished data (CRAM). Each threshold has an associated error rate; for example, 10% of reference sites are in Class 3 or 4, despite the fact that they are, by definition, intact.

Integrating Multiple Indicators

In order to determine a stream's overall condition, the four biological indicators were evaluated together to provide a comprehensive assessment of ecological health. To be considered intact for multiple indicators, all four indicators need to suggest that a stream is in reference condition. A single indicator below this threshold suggests that a stream is not in reference condition. To maintain an overall error rate of 10%, a site had to have scores above the 2.5th percentile of reference sites for each indicator (Table 1-1).

Weighted Magnitudes and Extent Estimates

Adjusted sample weights were calculated for each site. Because multiple surveys with different designs were included in analysis, weights needed to be recalculated for each site. Stratification approaches from all surveys were combined to create "cross-strata" in which all evaluated sites have an equal probability of being sampled. Adjusted weights were recalculated as the total stream length within each strata, divided by the number of sites evaluated in that stratum. Strata with no evaluations were excluded from analysis. Because these strata comprised less than 2% of the total stream length, these exclusions are unlikely to affect condition estimates. These weights were used to estimate distribution points for selected variables and extents for selected categories using the Horvitz-Thompson estimator (Horvitz-Thompson 1952). These estimates were calculated for reporting units of interest, including watersheds, land use classes, and (for trend estimates) years. Confidence intervals (CIs) were based on local neighborhood variance estimators (Stevens and Olsen 2004). All calculations were conducted using the *spsurvey* package (Kincaid and Olsen 2013) in R version 3.0.3 (R Core Team 2012).

Results

All data used in this report can be downloaded from <ftp.sccwrp.org/pub/download/SMCReport/SMCDataFor5yearReport.zip>.

Benthic Macroinvertebrates

Biological indicators suggested that most stream-kilometers in the survey's target population (i.e., perennial wadeable streams in southern coastal California) do not support healthy biology (Table 1-2a to c; Figures 1-1 and 1-2). For example, the mean CSCI score for the region was 0.77 and only 29% of stream-miles were in the top biological condition class for this indicator. Of the two components of the CSCI, the pMMI (which measures ecological structure) was more sensitive; the pMMI indicated that only 22% of South Coast stream-miles were in Class 1, whereas the O/E (which measures taxonomic completeness) indicated 46% were in Class 1.

The CSCI indicated that open streams were in better condition than agricultural streams, which were in turn better than urban streams. In fact, at open sites, mean CSCI scores were close to reference (i.e., 0.93), and only 5% of open stream-miles was in Class 4 (i.e., the worst condition class). In contrast, 31% of agricultural streams and 58% of urban streams were in Class 4.

Although this ranking of land use classes was evident with both components of the CSCI, the O/E generally categorized agricultural streams as intermediate between open and urban classes, whereas the difference was small when examined with the pMMI.

The watersheds with the greatest proportion of streams in Class 1 were located, roughly, in the northern and southern ends of the region, while the middle portions of the region had streams in poorer health. For example, the greatest extent of Class 1 stream-miles was located in the Ventura watershed (68%), followed by Southern San Diego (65%). These watersheds, along with the Santa Clara, all had mean CSCI scores greater than 0.9. The smallest extents of Class 1 stream-miles were observed in the Calleguas (9%), Central San Diego (10%), Lower Santa Ana (11%) and Middle Santa Ana (11%) watersheds.

Benthic Algae

In general, the algae indices showed similar patterns of regional stream condition as the CSCI (Table 1-2d and e; Figures 1-1 and 1-2). For example, the diatom index (D18) showed that 27% of stream-miles were in Class 1, while the soft algae index (S2) showed that 25% were in this class; these numbers are only slightly less than the estimate for the CSCI (i.e., 29%).

In contrast with the CSCI, algae-based indices only weakly differentiated between urban and agricultural streams, and estimated both to be in far worse condition than open streams. For example, D18 rarely identified developed streams as Class 1 (Agricultural: 11%; Urban: 2%). Uniquely, S2 scores were generally lower at agricultural streams (mean: 26) than urban streams (mean: 32). In contrast, mean D18 scores were similar in both urban (43) and agricultural (45) streams.

Although there were some differences among the two algae indices, they both showed that the watersheds in the northern portions of the region had the greatest extent of streams in Class 1. For example, D18 indicated the greatest extent of streams in Class 1 in the Ventura (84%) and Upper Santa Ana (63%,) watersheds, whereas S2 indicated the greatest extent of stream-miles in Class 1 in the Upper Santa Ana (47%) and Santa Clara (46%) watersheds. Depending on the index used, Class 1 streams were rarely or never observed in the Calleguas, Santa Monica Bay, Lower Santa Ana, San Juan, and Central San Diego watersheds.

Riparian Condition

Most streams in southern California did not support healthy riparian communities, as only 30% of stream-miles in the region had CRAM scores in the top condition class (i.e., a CRAM score \geq 79), and the mean CRAM score (64) was much lower than the reference mean (i.e., 84).

However, the extent of stream-miles in Class 1 was greater for individual attributes (e.g., 40% for the landscape and buffer attribute), indicating that different attributes limit overall riparian condition at different sites (Table 1-2f; Figures 1-1 and 1-2).

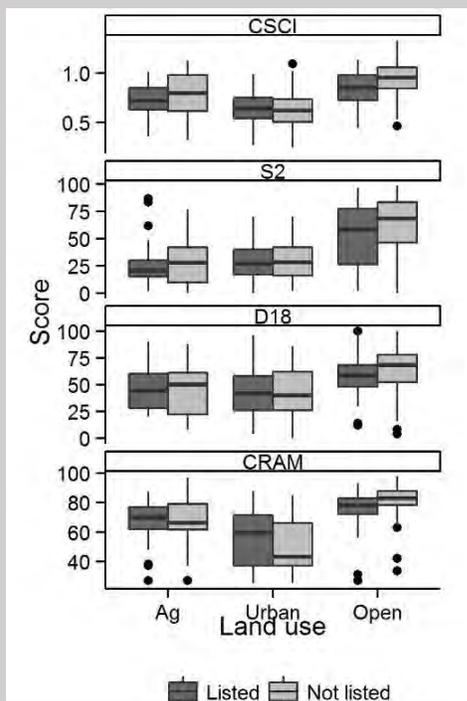

Land use was strongly associated with CRAM scores, even more so than with other indicators. For example, Class 1 CRAM scores were observed at 65% of open stream-miles (mean: 81), but only 20% of agricultural streams (mean: 68) and 7% of urban stream-miles (mean: 51). This contrast was particularly strong at the attribute level (especially the buffer and landscape attribute). For example, hydrologic conditions were in the top class at 57% of open stream-miles, but only 17% of agricultural stream-miles and 17% of urban stream-miles.

Class 1 riparian conditions were observed at the majority of stream-miles within five watersheds that were geographically dispersed across the region, with the greatest extents in the San Jacinto (63%) and Northern San Diego (57%) watersheds, followed by Ventura (54%) and Southern San Diego (52%). Streams with Class 1 riparian condition were scarce in the Calleguas (3%) and Los Angeles (14%) watersheds. Across the four attributes, four watersheds ranked among the worst in terms of the extent of streams in Class 4: Los Angeles, San Gabriel, Lower Santa Ana and Middle Santa Ana. All attributes were in the worst condition class for at least 50% of these watersheds (Table 1-2g to j) with the exception of the biotic structure attribute in the Lower Santa Ana (36% in Class 4).

303(d)-Listed Streams

The State Water Resources Control Board has designated approximately 2000 stream-kilometers in southern California as impaired for water quality pursuant to Section 303(d) of the Clean Water Act. Streams are usually listed as “impaired” due to exceedances of a chemical water quality standard. The potential relationship between designated impairments and instream biological condition was evaluated by comparing biological index scores from streams listed as impaired to streams from comparable land use categories that are not listed. Listed streams were obtained from the State Water Board 303(d) list; in Ventura and Riverside counties, agency staff modified this list by reclassifying listings believed to be unrelated to aquatic life uses (e.g., bacteria) as “not listed” for this analysis.

Land use was more strongly associated with scores than with status on the 303(d) list. For example, scores at urban and agricultural sites were lower than scores at open sites, whether or not the sites were included on the 303(d) list. There was no significant difference in scores between listed and unlisted streams at urban or agricultural sites. Scores at open listed sites were slightly lower than at open unlisted sites; however, this difference was small, and the proportion of Class 3 or 4 sites was no greater at open listed sites than open unlisted sites.

Index scores based on benthic macroinvertebrates (CSCI), soft algae (S2), diatoms (D18) and riparian condition (CRAM) for 303(d)-listed and unlisted streams, by land use.

Condition of Engineered Channels: Exploring options for alternative thresholds

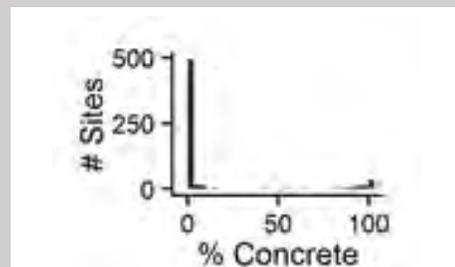

Many of the streams in this survey have been engineered to some degree for flood management purposes, and these engineered features may constrain biological condition. Therefore, we estimated the biological condition of streams with engineered channels relative to those with natural channels. The best condition observed in engineered channels may be a more realistic threshold than a reference-based threshold, assuming that the effects of channel engineering cannot be mitigated. If the best observed condition in engineered channels is substantially below a reference-based threshold, an alternative threshold may be appropriate.

Because consistently derived region-wide maps identifying the location of engineered channels are not available, habitat data was used to classify streams as likely concrete-lined (i.e., at least 5% concrete in the streambed), or likely non-concrete lined (i.e., less than 5% concrete in the streambed). This approach overlooks forms of engineered channels that do not use concrete, such as ungrouted rock, while also misclassifying streams affected by other types of concrete structures, such as road crossings. It also ignores the substantial variation of channel forms in engineered systems, which may affect biological condition. But despite these shortcomings, this approach represents a useful starting point until better data are available about engineered channels.

Overall, approximately 26% of perennial stream-miles were estimated to be concrete-lined. About half of urban streams were concrete lined and 13% of agricultural streams, but only 2% of open streams. Concrete-lined streams comprised a majority of stream-miles in the Los Angeles and San Gabriel watersheds, but none were sampled in the Northern and Southern San Diego watersheds.

Extent of concrete channels in southern California

Subpopulation	Concrete-Lined Channels	
	# sites	% stream-miles
South Coast	130	26
<i>Land use</i>		
Urban	107	53
Open	10	2
Agricultural	13	13
<i>Watershed</i>

Santa Clara	3	3
Calleguas	12	29
Santa Monica Bay	13	19
Los Angeles	22	51
San Gabriel	23	69
Santa Ana Region		
Lower Santa Ana	11	26
Middle Santa Ana	22	41
Upper Santa Ana	1	2
San Jacinto	5	19
Northern San Diego		
San Juan	6	24
Northern San Diego	0	0
Mission Bay and San Diego River	6	24
Central San Diego	4	14
Southern San Diego	0	0

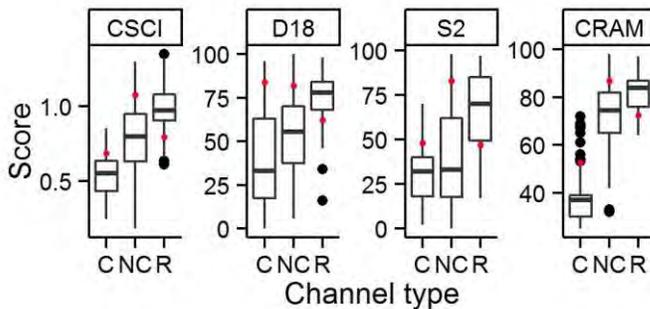

% concrete substrate at each sampled site. Concrete was absent from most sites, but comprised nearly 100% for a small handful of sites. Intermediate values were rarely observed.

Condition of Engineered Channels (Continued)

To investigate the constraints concrete lining imposes on biological condition, sites were divided into three classes: concrete-lined, no concrete, and reference. The range of index scores within each class was examined by creating boxplots. For indices where the 90th percentile of concrete-lined channels is less than the 10th percentile of reference streams, lower thresholds may be appropriate.

In general, scores of all indices were lower in concrete-lined channels than in reference streams, suggesting that these streams were typically in poor condition. For most indices the highest scores in concrete-lined channels were lower than lowest scores observed at reference sites (estimated at the 90th and 10th percentiles, respectively). For example, the 90th percentile of CSCI scores was 0.69 (i.e., “Class 3”), suggesting that an alternative threshold may reflect a more attainable management objective than the 10th percentile of reference sites. Additional data and analyses (particularly on channel type) are needed if alternative thresholds for concrete-lined channels are used for regulatory purposes.

In contrast, this analysis did not support alternative thresholds for algae indices. High scores were frequently observed in concrete-lined channels. In fact, the 90th percentile of D18 scores in concrete-lined channels was 84, which is substantially higher than the threshold based on the 10th percentile of reference sites (i.e., 62). Therefore, it is probable that low D18 and S2 scores in concrete-lined channels are attributable to impacts not directly related to channelization, and may instead be related to water quality impacts.

Distribution of scores at concrete-lined channels (C), nonconcrete-lined channels (NC), and reference streams (R). The red dot represents the 90th percentile of scores of concrete- and nonconcrete-lined channels and the 10th percentile of reference streams.

Options for setting thresholds in concrete-lined channels. A traditional approach is based on the distribution of scores at reference sites, whereas an alternative approach is based on the distribution of scores at concrete-lined channels. These numbers reflect preliminary analyses.

Index	Option 1: Threshold based on reference	Option 2: Threshold based on concrete-lined channels
CSCI	0.79	0.68
D18	62	84
S2	47	48
CRAM	72	53

Multiple indicators

Only 25% of streams-miles in the region were intact for all four indices, and these conditions were almost exclusively observed at streams with undeveloped watersheds (Table 1-3, Figures 1-3 and 1-4). Overall, 60% of open stream-miles were in this category. Streams with index scores above the multi thresholds were absent from the Calleguas watershed and scarce in Santa Monica Bay, Los Angeles, Middle Santa Ana, and Central San Diego watersheds. In contrast, a majority

of stream-miles were intact for multiple indicators in the Upper Santa Ana (62%), Southern San Diego (61%), San Jacinto (53%) and Ventura (50%) watersheds.

Most commonly, streams were limited (i.e., below the “multi” threshold) for multiple indicators, and all four indicators were identified as limiting for 15% of stream-miles region-wide (Table 1-3; Figures 1-3 and 1-4). More than a quarter of stream-miles were limited for all indicators in certain watersheds (specifically, Calleguas, Los Angeles, Lower Santa Ana, and San Jacinto watersheds) and in urban streams, but this situation was rare in other watersheds (specifically, Ventura, Upper Santa Ana, Northern San Diego, and Mission Bay and San Diego watersheds), and in open streams. Streams limited for single indicators were more extensive in these open streams, and algae indices (D18, S2, or both) were most commonly the only limiting indicator. For example, 41% of stream-miles in the Northern San Diego and 37% in the Ventura watersheds were limited for D18 or S2, but not CRAM or CSCI.

Discussion

The scarcity of streams with intact biology may prompt managers to evaluate ways to protect these streams, or improve the condition of streams where indicators suggest altered biological condition. The emphasis may vary from protection in one part of the region to rehabilitation in another, depending on local needs and interests. However, many watershed managers in southern California would benefit from a coordinated approach towards prioritizing local objectives, given the extent of streams with altered biology. Uncoordinated efforts to address pervasive challenges have historically met with little success (Bernstein and Schiff 2002).

Multiple indicators proved valuable for several reasons. 1) Redundancy improves precision and guards against incorrect conclusions from sampling error or natural variability. 2) The different life histories of each indicator provided a broader assessment of ecosystem function. 3) The unique properties of the indices increase overall sensitivity to different stressors. 4) The different responsiveness of the indices allows better discrimination among condition-classes along the biological condition gradient.

The identification of “limiting indicators” may provide initial steps towards diagnosing stressors or prioritizing sites for rehabilitation. The fact that so many streams were limited for multiple indicators (frequently all four indicators used in the survey) suggests that pressures on many streams are diverse, severe, or both, and fixing these streams may be major challenge. But 19% of the region was limited for a single indicator, and this may indicate that pressures are less severe or more similar in action; rehabilitating these streams may be a more surmountable challenge than streams with fewer indicators in intact condition.

Table 1-1. Thresholds for identifying non-reference condition for biological indicators. Ref mean: Mean of reference sites. Ref SD: Standard deviation of reference sites. Numbers in parentheses refer to the percentiles used to set boundaries between classes. “Multi” refers to the threshold used in multiple-indicator analyses (i.e., the 2.5th percentile); samples with scores above all “multi” thresholds are considered to be in reference condition, with a 10% error rate.

Index	Ref N	Ref mean	Ref SD	Class 1 (≥30 th Intact)	Class 2 (10 th to 30 th)	Class 3 (1 st to 10 th)	Class 4 (<1 st Altered)	Multi
Benthic Macroinvertebrates								
CSCI	479	1.00	0.16	≥0.92	0.79 to 0.92	0.63 to 0.79	<0.63	0.69
-pMMI	479	1.00	0.18	≥0.91	0.77 to 0.91	0.58 to 0.77	<0.58	--
-OE	479	1.00	0.19	≥0.90	0.76 to 0.90	0.56 to 0.76	<0.56	--
Benthic Algae								
D18	122	79	13	≥72	62 to 72	49 to 62	<49	54
S2	122	69	17	≥60	47 to 60	29 to 47	<29	69
CRAM								
Overall Score	86	84	9	≥79	72 to 79	63 to 72	<63	66
Buffer and Landscape	86	95	10	≥90	82 to 90	72 to 82	<72	--
Hydrologic Connectivity	86	81	13	≥74	64 to 74	51 to 64	<51	--
Physical Structure	86	81	16	≥73	60 to 73	44 to 60	<44	--
Biotic Structure	86	75	16	≥67	54 to 67	38 to 54	<38	--

Table 1-2a: Mean CSCI scores and extent estimates for each condition class. n: number of sites used in the analysis. SD: Standard deviation. Class 1: % of streams with scores above the 30th percentile of reference sites. Class 2: % of streams with scores between the 10th and 30th percentiles of reference sites. Class 3: % of streams with scores between the 1st and 10th percentiles of reference sites. Class 4: % of streams with scores below the 1st percentile of reference sites.

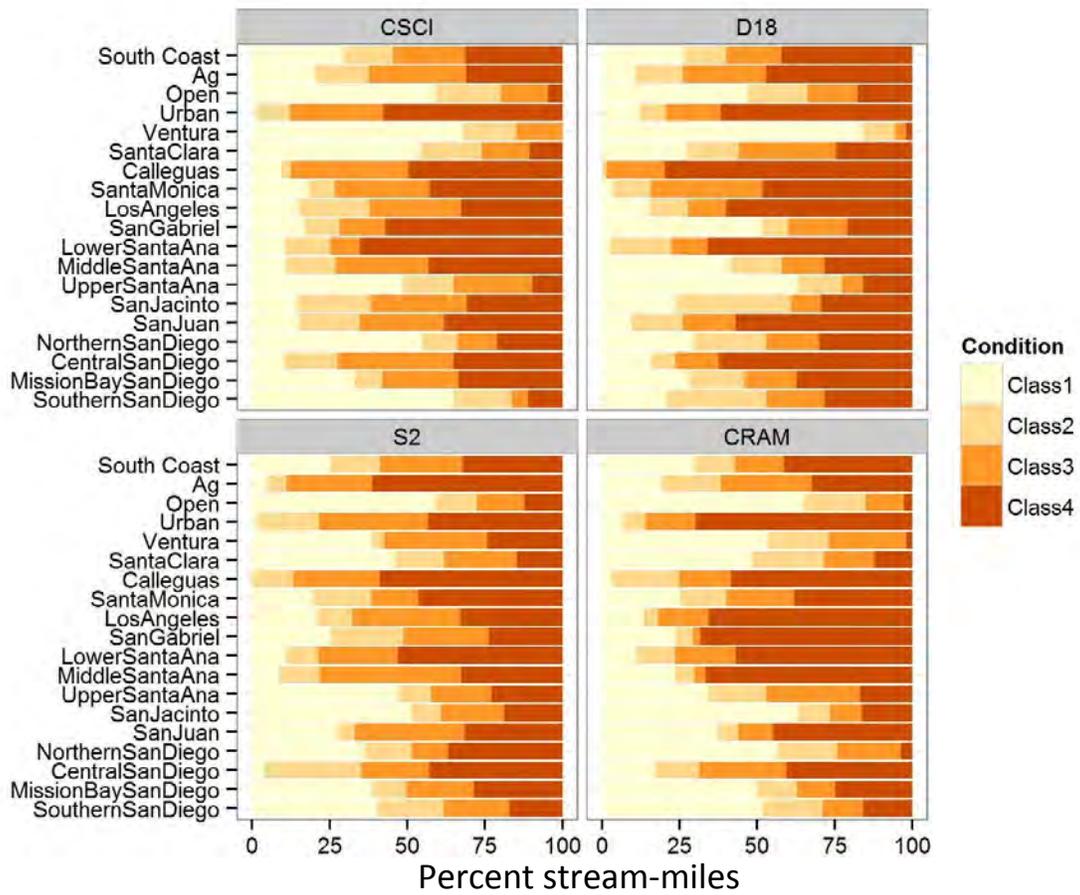

Figure 1-1. Percent of stream-miles in each condition class for each indicator by subpopulation.

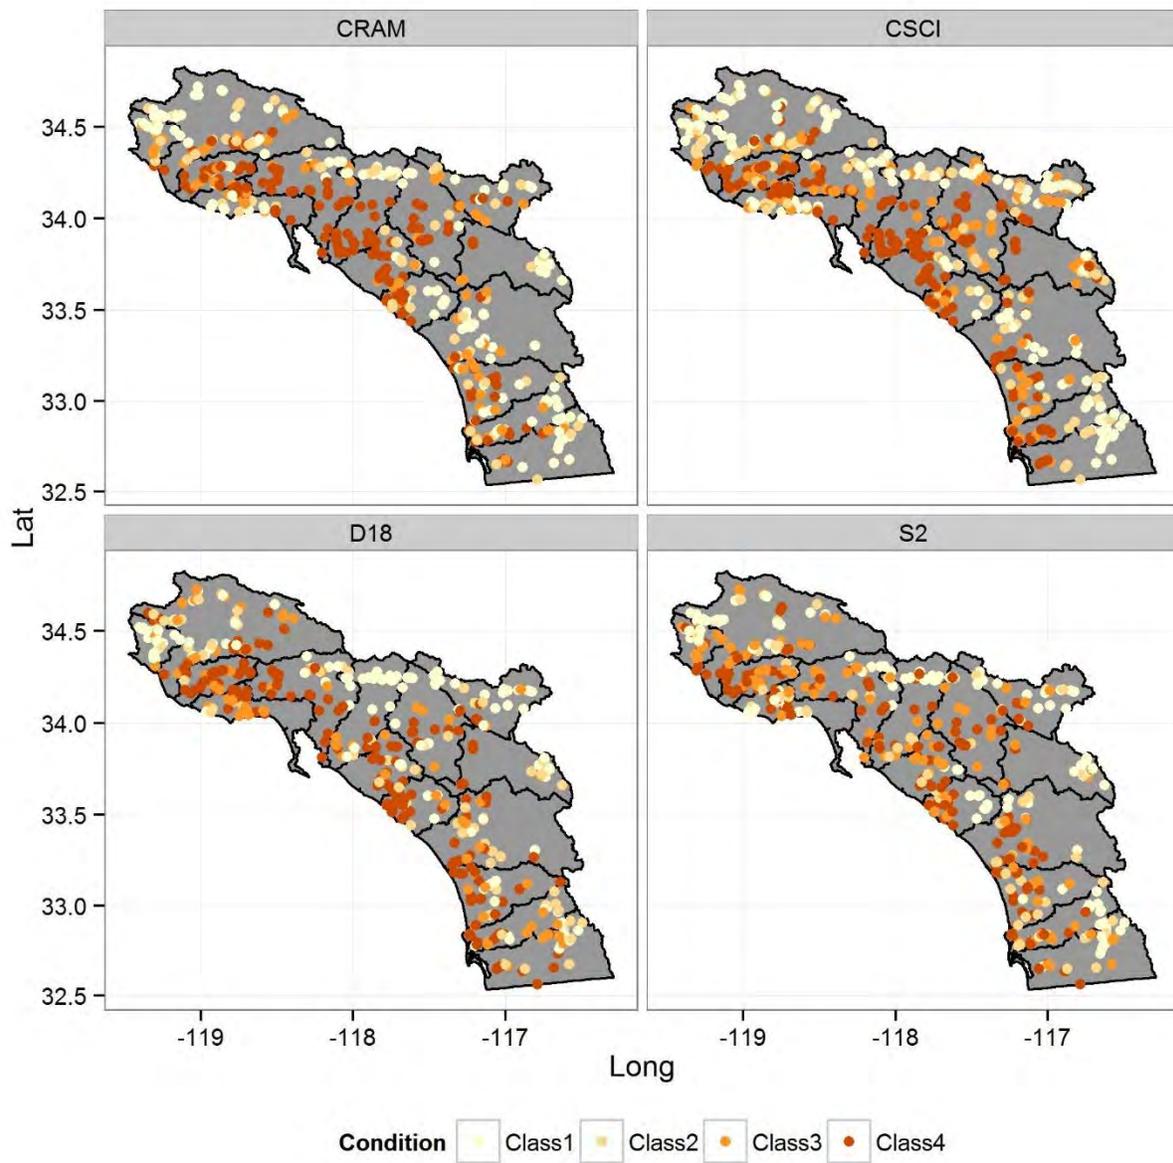

Figure 1-2. Map of scores for key indicators.

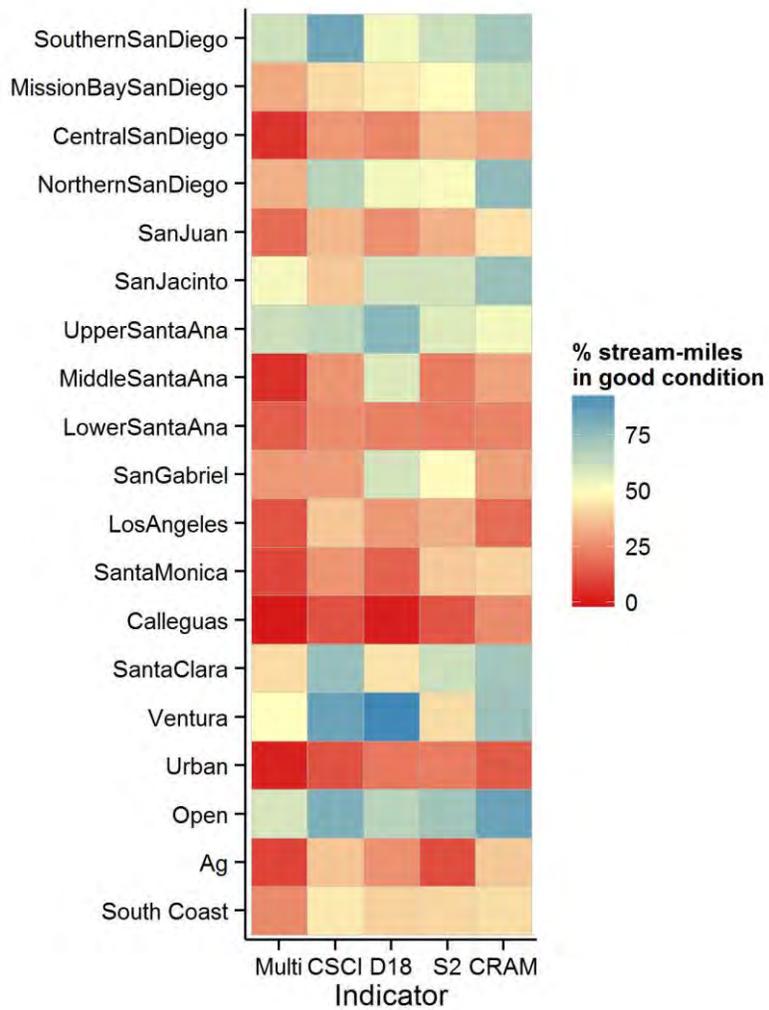

Figure 1-3. Percent of stream-miles in good condition by subpopulation. For the “multi” column, the number reflects the percent of stream-miles with scores for all indicators above the 2.5th percentile of reference sites; all other columns reflect the percent of stream-miles with scores above the 10th percentile of reference sites.

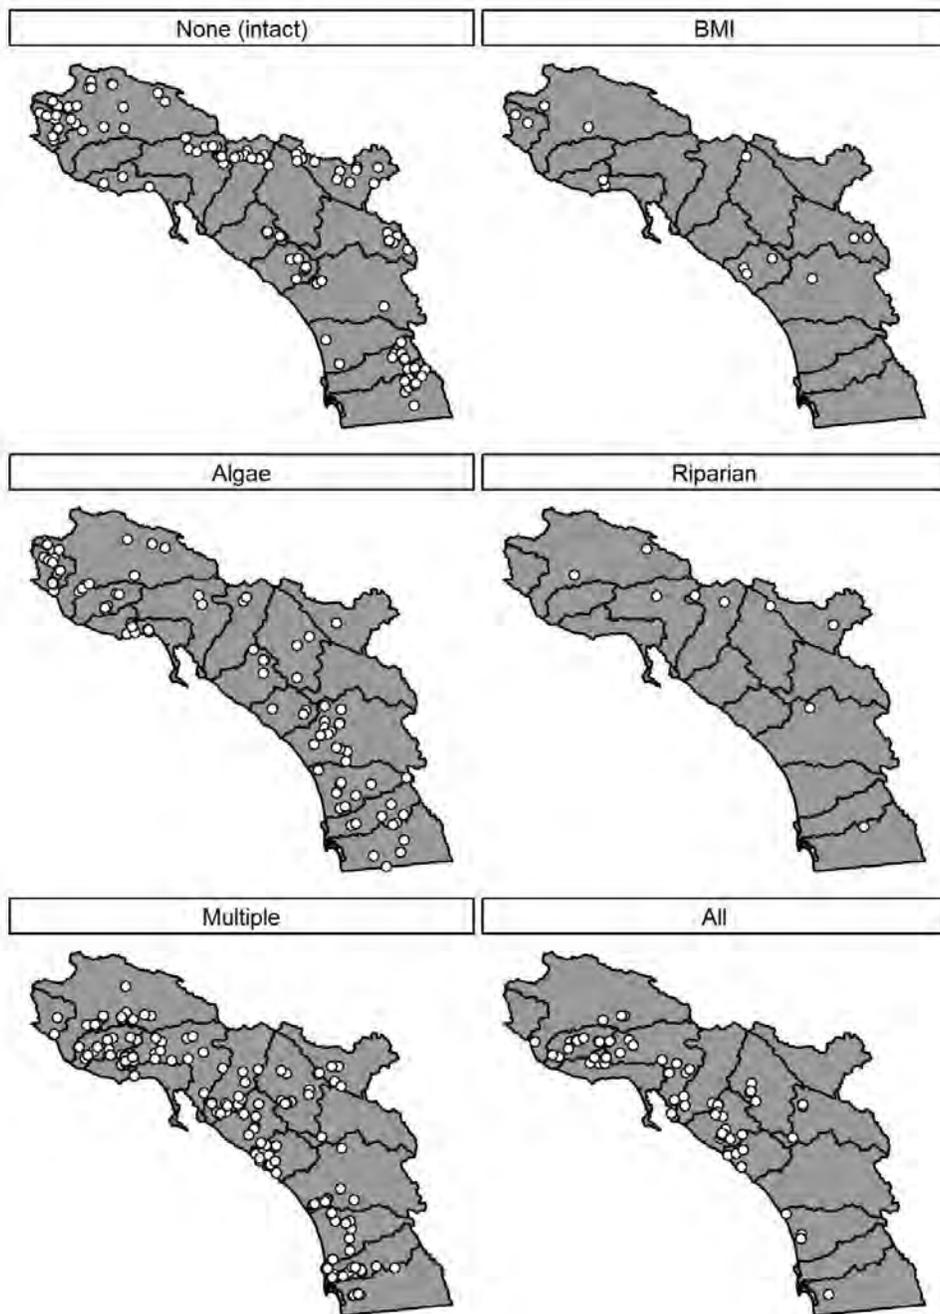

Figure 1-4. Map of limiting indicators. In the top left panel, points represent sites where scores for all four indicators above the 2.5th percentile of reference sites. For all other panels, points represent sites where scores for the specified indicator or indicators were below the 2.5th percentile of reference sites.

QUESTION 2: WHICH STRESSORS ARE ASSOCIATED WITH POOR BIOLOGICAL CONDITION?

Caballero Creek, in the Los Angeles watershed, exemplifies both the severe habitat alteration and nutrient enrichment that affects many streams in southern California.

Introduction

Although the direct measurement of stressors cannot determine the ecological health of a stream, it is essential in determining which factors may limit its health, and provides essential data to inform causal assessment at degraded sites. The SMC stream survey took a notably broad approach towards assessing stressors, measuring nutrients, total and dissolved metals, major ions, water column toxicity, and physical habitat. For some constituents, this survey represents the first unbiased estimate of the extent and magnitude of stressors in aquatic systems. By assessing the extent of these stressors and assessing their associations with biological condition, this survey allows the prioritization of stressors of regional interest, which can then inform local management decisions.

Methods

Data Collection

Data were collected as described in the Survey Overview.

Data Aggregation

Where multiple samples were collected at a single site within a year, data were aggregated as the maximum value within a site. Multi-year mean values for each site were then calculated from these aggregated values if sites were revisited in multiple years. Missing values were ignored for all relevant analyses, where appropriate.

Thresholds

Our goal in setting stressor thresholds was to prioritize stressors in terms of their associated risks to biological condition, as opposed to validating the adequacy of existing regulatory thresholds or assessing compliance with permit requirements. Therefore, the best threshold for this goal is one that is associated with the biggest change in biological condition. Stressor thresholds do not necessarily reflect the most appropriate water quality standards for a given site, which may vary based on site-specific conditions. Therefore, exceeding one of the stressor thresholds used in this analysis may not necessarily indicate impairment or noncompliance with permit requirements.

Stressor thresholds were derived from values published in relevant literature or regulations, where possible (Tables 2-1, 2-2). For chemical nutrients and for most habitat metrics (which are occur naturally and do not have regionally applicable regulatory thresholds), thresholds were established at the 90th or 10th percentile of the distribution among reference sites (as per Ode *et al.* In review). For pyrethroids without published thresholds, a threshold of zero was used.

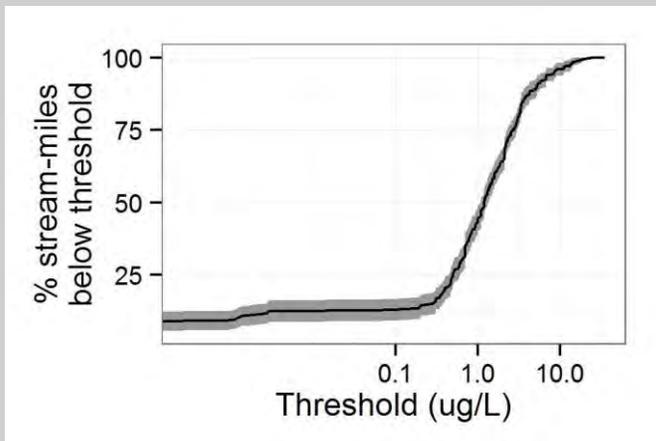

Toxicity tests were compared against controls. If endpoints were significantly different from controls and had values that were 80% of control values or lower, the samples were considered toxic. Toxic survival endpoints were given precedence over nonlethal endpoints (e.g., depressed reproduction).

Reference-Based Thresholds

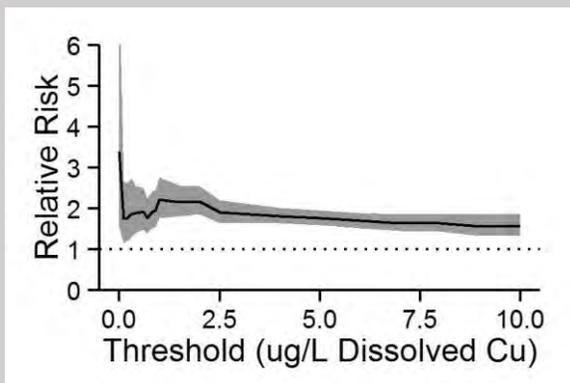

Reference-based thresholds, while appropriate for assessing whether biological indices reflect reference condition, may not be appropriate for water chemistry or physical habitat variables, as they may be excessively stringent. Because of uncertainty about the applicability of certain water chemistry thresholds, a number of alternative thresholds recommended by participating agencies were evaluated.

Copper

To evaluate the impacts of metals on stream condition, this survey used hardness-adjusted thresholds from the California Toxics Rule (EPA 2000). These thresholds are intended to prevent toxic effects on a variety of aquatic species based on the concentration of bio-available toxicants. However, because many of these metals have natural geological sources in the region (e.g., Yoon and Stein 2008), a reference-based threshold, such as those used for nutrients, would better identify sites that exceed natural concentrations. Therefore, a reference-based threshold for copper was calculated as the 90th percentile of concentrations at reference sites within the South Coast region (i.e., 3.4 ug/L), and the extent of stream-miles below this threshold was estimated. Whereas 96% of stream-miles across the region were below the hardness-adjusted threshold for total copper, only 67% were below the reference-based threshold. The difference was even greater for dissolved Copper: 99% of stream-miles were below the hardness-adjusted CTR threshold, whereas only 39% were below the reference threshold of 0.8. Relative risk estimates were only marginally affected (e.g., risk to CSCI scores went up from 1.7 to 1.9 for dissolved copper). However, attributable risks increased considerably (e.g., from 0.004 to 0.360), reflecting the larger number of stream-miles exceeding the reference-based threshold, which would have increased the priority given to this stressor.

Effects of varying thresholds on the percent of perennial stream-miles below threshold for dissolved copper. The gray band indicates the 95% confidence interval.

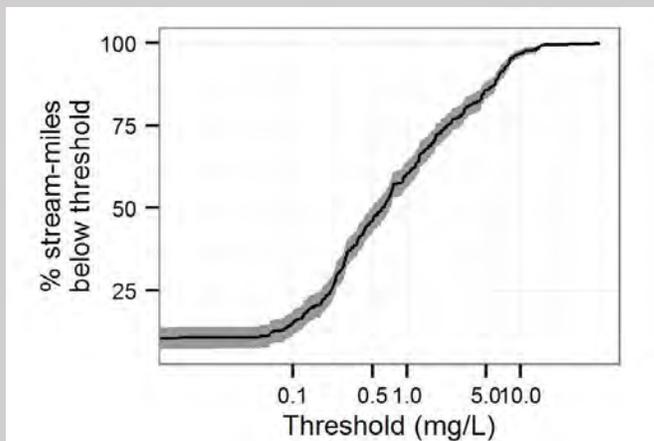

Risk to CSCI scores remain high at all levels of dissolved copper analyzed. The gray band represents the 95% confidence interval. Relative risks greater than 1 (represented by the dotted line) indicate that the stressor is associated with poor biological condition.

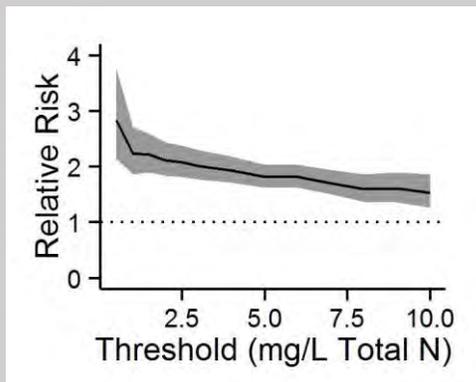

Reference-Based Thresholds (Continued)

Total Nitrogen

This study and others (see Herlihy and Sifneos 2008) have shown a strong association between nutrient concentrations and poor biological condition. However, the reference based thresholds used here are much lower than those used in basin plans or TMDLs throughout the region. For example, the reference-based threshold for total nitrogen (TN) was 0.37 mg/L, whereas the San Diego Basin Plan specifies a threshold of 1 mg/L. The Los Angeles Basin Plan sets a much higher threshold of 10 mg/L (although this threshold is explicitly linked to risks to human health and municipal water uses, not aquatic life). Although 39% of stream-miles across the region were below the reference threshold, this number increased to 60% if a threshold of 1 mg/L was used, and to 98% if a threshold of 10 mg/L was used.

Effect of varying thresholds on the percent of perennial stream-miles below threshold for total nitrogen. The gray band indicates the 95% confidence interval.

Risk to CSCI scores remain high at all levels of total N analyzed. The gray band represents the 95% confidence interval. Relative risks greater than 1 (represented by the dotted line) indicate that the stressor is associated with poor biological condition.

Stressor Extent Estimates

Extent estimates and related distribution points were calculated as described in the Survey Overview. These estimates were calculated for land use classes and for the region as a whole, but not for individual watersheds.

Stressor Associations and Prioritization

Relative risk analysis was used to estimate the likelihood of poor biological condition given the presence of a stressor, relative to the likelihood in the absence of a stressor (Van Sickle *et al.* 2006). Attributable risk analysis was then used to estimate the proportion of streams in the region where biological condition may improve if a stressor were removed. Biological condition was determined as described in the section on Question 1, except that Class 1 and 2 streams (Table 1-1) were both treated as “good”, and Class 3 and 4 streams were both treated as “poor”.

Stressors were then designated as very high priority (attributable risk > 25% of the region for any indicator), high priority (attributable risk between 10% and 25% for any indicator), moderate (attributable risk <10%, but relative risk > 1 for any indicator), and low (relative risk <1 for all indicators).

Relative and Attributable Risk

Relative risk assessment is statistical method of associating the increased risk associated with a stressor (Van Sickle *et al.* 2006). Originally developed for public health studies, relative risk analysis has become popular in environmental assessment because it facilitates prioritization of stressors by identifying which ones are most strongly associated with poor condition. Relative risk compares the odds of observing poor biological condition when a stressor is present to the odds of observing it when the stressor is absent:

$$\text{Relative risk} = \frac{\text{Proportion of stressed stream-miles in poor condition}}{\text{Proportion of unstressed stream-miles in poor condition}}$$

Stressors with relative risks greater than 1 are considered to be associated with poor condition; larger relative risks indicate stronger associations, although any stressor with a risk greater than 1 is a good candidate for further study (e.g., causal analysis).

Relative risk analysis can be extended through attributable risk analysis, which accounts for the fact that low-risk but extensive stressors may be higher regional priorities than high-risk stressors that affect few stream miles (Van Sickle and Paulsen 2008). Attributable risk is calculated as follows:

$$\text{Attributable risk} = \frac{(\text{Proportion of stressed stream-miles}) \times (\text{Relative risk} - 1)}{1 + (\text{Proportion of stressed stream-miles}) \times (\text{Relative risk} - 1)}$$

Thus, the attributable risk of a stressor is large if a stressor is extensive and has a relative risk greater than 1. If one assumes a perfect causal relationship between the stressor and poor condition, the attributable risk represents the proportion of the region that would be improved if the stressor were eliminated (Van Sickle and Paulsen 2008). But even when this assumption is violated, attributable risk is a useful metric for ranking stressors by regional importance because it accounts for both stressor extent and strength of association with biological condition.

Both relative risk and attributable risk require stressor thresholds for calculation, and modifying the threshold may alter estimates of risk. If stressor thresholds are set too high, relative risk estimates will go down as the proportion of unstressed stream-miles in poor condition increases. Similarly, if stressor thresholds are set too low, relative risk estimates will also go down as the proportion of stressed stream-miles in poor condition decreases. Ideally, stressor thresholds are set at the level where streams are most likely to switch from poor to good condition (or vice-versa), thereby allowing more direct comparisons of risk across stressors.

Results

All data used in this report can be downloaded from <ftp.sccwrp.org/pub/download/SMCReport/SMCDataFor5yearReport.zip>.

Stressor Extents

Regional results for all analytes are presented, but only subpopulations where at least 5% of the stream-miles exceeded the threshold are included.

Water Chemistry

In general, nutrients and sulfate exceeded the threshold in extensive portions of the region, while exceedances of pyrethroids and metals were rare (Table 2-3a, Figures 2-1 and 2-2). For example, total Nitrogen exceeded the reference benchmark of 0.37 mg/L in 61% of stream-miles

across the region, and sulfates exceeded the benchmark of 250 mg/L in 45% of stream-miles. In contrast, Bifenthrin, the most commonly detected pyrethroid, exceeded the benchmark of 0.0006 ug/L in only 16% of stream-miles, and Selenium exceeded the threshold of 5 ug/L in only 13% of stream-miles. Even within urban areas, pyrethroid and metal exceedances were observed in fewer than 24% of stream-miles (Table 2-3b). Several analytes (e.g., Alkalinity, Arsenic, Nickel, and Zinc) were within thresholds at all sites in the survey. Nonetheless, exceedances of certain constituents were extensive in individual watersheds (Table 2-3c). For example, Bifenthrin exceeded the benchmark in 35% of stream-miles in the Santa Monica Bay watershed, and 30% of the Lower Santa Ana, whereas Selenium exceeded its threshold in 40% of the Calleguas and 55% of the Santa Monica Bay watersheds. Geographic clustering of exceedances was evident for both Selenium and Chloride (Figure 2-2), suggesting a localized (perhaps geological) source for these constituents. Exceedances of the reference-based threshold for total dissolved solids (TDS; i.e., 498 mg/L) were also widespread, affecting 76% of stream-miles region-wide, and nearly all agricultural (97%) and urban (99%) stream-miles. However, a large extent (50%) of open stream-miles also exceeded this threshold, as did 100% of certain watersheds (i.e., Calleguas, Santa Monica, and Lower Santa Ana).

With the exception of Ammonia (whose threshold is based on its toxicity to aquatic invertebrates), nutrients frequently exceeded their benchmarks, based on concentrations observed at reference sites, and these extents were closely related to land use. For example, 71% of open streams were below the threshold for total nitrogen (TN), yet only 12% of urban and 13% of agricultural streams had similarly low concentrations of nitrogen. Exceedances for TN were relatively limited in the Ventura (26%) and Santa Clara (30%) watersheds, but pervasive within the Calleguas (94%) and Lower Santa Ana (90%) watersheds. Total phosphorous (TP) exceedances exhibited similar patterns. For example, 57% of stream-miles exceeded the reference-based benchmark of 0.03 mg/L. As with nitrogen, phosphorous exceedances were pervasive in urban (83% of stream-miles) and agricultural (72%) land uses, and were relatively common in open streams (29%).

Toxicity

Toxicity was detected in surprising geographic patterns. Sublethal toxicity (i.e., depressed reproduction) was somewhat common (evident in 25% of stream-length), and was more extensive in open (33%) than agricultural (30%) or urban (19%) streams (Table 2-4, Figure 2-3). Sublethal toxicity was particularly extensive in the Los Angeles (57%) and Santa Clara (49%) watersheds, but rare within neighboring watersheds, like the San Gabriel (6%) and Calleguas (8%) watersheds. In contrast, toxicity to survival endpoints was evident in only 6% of streams region-wide, and was less extensive in open streams (2%) than urban (8%) or agricultural (15%). Lethal toxicity was most extensive in the Central San Diego watershed (26%), but was fairly limited (extent <10%) in most other watersheds.

Physical habitat

Region-wide, the majority of stream-miles were within the reference distribution for all habitat variables examined, although the more aggregated measures of habitat condition tended to show the most extensive alteration (Table 2-5). For example, the three diversity metrics (i.e., Shannon_Flow, Shannon_Habitat, and Shannon_Substrate), as well as the fish cover metric (i.e., XFC_NAT_SWAMP) were depressed for more than 25% of stream-miles in the region (Figures 2-4 and 2-5).

With the exception of algal biomass variables, the extent of open streams exceeding a benchmark was typically close to the expected distribution at reference sites (i.e., 10%). For example, the Shannon flow metric was outside threshold in 32% of urban stream-miles, 20% of agricultural stream-miles, and only 7% of open stream-miles. This pattern, with the greatest extent of streams exceeding thresholds in urban, followed by agricultural streams, was typical of most habitat variables. A notable exception includes variables directly related to fine sediment (e.g., % sands and fines (PCT_SAFN) and % cobble embeddedness (XEMBED)) were more extensively above threshold in agricultural streams than in urban streams; these metrics may reflect channelization or other flood-control activities that reduce particulate substrates (such as cobbles and sand grains) in urban streams.

Biomass variables frequently exceeded reference-based thresholds across different land-use types, including undeveloped streams. For example, macroalgae cover (i.e., PCT_MAP) exceeded the threshold in 42% of urban streams, 31% of agricultural streams, and 17% of open streams. In contrast, variables related to habitat complexity or riparian vegetation showed a more familiar pattern across land use types.

The extent of altered habitat varied widely by watershed. For example, the extent of exceedances of biomass thresholds was about a third or less for most watersheds, with the notable exception of benthic Chlorophyll a and ash-free dry mass, where exceedances affected nearly two-thirds of the Santa Monica Bay watershed. The exceedances of the Shannon habitat metric affected 3% or less of the Ventura and Northern San Diego watersheds, but more than half of the Los Angeles, San Gabriel, and Middle Santa Ana watersheds. In fact, exceedances affected more than 50% of these three watersheds for many habitat variables.

Stressor prioritization

Nutrients, variables related to ionic concentration (e.g., TDS, sulfates), and several habitat variables were classified as very high priority stressors, having both high relative and attributable risks for several indicators (Tables 2-6 and 2-7, Figure 2-6). For example, TN had an attributable risk of 0.51 for the CSCI. Total dissolved solids and sulfate were also high priority because of their high attributable risk for the CSCI and S2. In contrast, metals and pyrethroids were typically classified as moderate priority. Some, like Bifenthrin or copper, had comparatively high relative risks (>1.5), but because of their limited extents, were estimated to

affect less than 10% of the region. Variables related to biomass were also classified as moderate, but for the opposite reason: low risk, but extensive exceedances of threshold contributed to elevated attributable risks.

While there was general agreement among indices, risks were overall greater for the CSCI, followed by S2, with D18 showing the lowest risks. The same five stressors (TDS, PCT_BIGR, W1_HALL, TP, and TN) had the highest attributable risk for all indices. Copper and XEMBED had relatively high attributable risk for the algae indices, compared to the CSCI, which in turn had higher risk for several habitat complexity measures (e.g., Shannon_Substrate, XPCMG).

Discussion

Nutrients, altered physical habitat, and major ions were both widespread and strongly associated with altered biology. Although metals and pyrethroids may be important stressors at specific sites, they should be considered a lower priority for regional programs (generally because they affected only a limited extent of streams).

Although physical habitat was repeatedly identified as a high-risk stressor, it was not possible to characterize these impacts in a precise, unbiased manner. Many physical habitat variables show large site-to-site variability within undisturbed areas, reflecting the influence of environmental gradients, like watershed size, climate, and geology. Establishing site-specific benchmarks based on environmental setting would probably yield a more accurate assessment of physical habitat. Data collected at reference sites could be used to develop models that can set these benchmarks for different stream types. Additionally, integrating multiple physical habitat variables into one or more indices would probably provide a more comprehensive characterization of habitat condition than the metric-by-metric approach used here.

Why were nutrients so strongly associated with poor biology if elevated biomass, the presumed mechanism of impact, had only a moderately high risk? This apparent conflict could result from several possible reasons: 1) timing of sampling, which may miss peak algae biomass; 2) co-occurrence with other stressors (such as habitat alteration; Bernal *et al.* 2013), or 3) other mechanisms of impact, such as cyanotoxins or microcystins (e.g., Aboal *et al.* 2002). Because nutrients are such a high priority for the region, further investigation of these explanations may be warranted.

Table 2-1. Analyte threshold by category. Asterisks indicate thresholds that were used when hardness data were unavailable.

Table 2-6. Relative (RR) and attributable (AR) risks for selected indicators. n: number of sites included in the analysis. 95% CI: 95% confidence interval around estimate. (t) indicates that the total fraction of metals were used in the analysis. (d) indicates that the dissolved fraction of metals were used in the analysis. VH: Very high priority (i.e., attributable risk ≥ 0.25 for at least 1 indicator). H: High priority (i.e., attributable risk ≥ 0.1 for at least 1 indicator). M: Moderate priority (i.e., relative risk > 1). L: Low priority (relative risk ≤ 1). Physical habitat variable abbreviations are provided in Table 2-2. *Some chemistry variables are excluded because they had too few exceedances of thresholds to permit relative risk analysis.

QUESTION 3: HOW ARE BIOLOGICAL CONDITIONS CHANGING OVER TIME?

Murrieta Creek, Fall 2003

Murrieta Creek, Spring 2004

Changes in land use, such as the installation of a sand mining operation, can profoundly alter the habitat and degrade biological condition.

Photos by Scott Johnson.

Introduction

Analysis of trends allows managers to assess the effects of policies that have been implemented during the study period, the influence of disturbances like wildfire, or other activities that might change the biological condition of streams in the region. Changes observed in the region provide context to understanding site specific changes. For example, if conditions deteriorate in less disturbed areas (such as open streams), then degradation observed at an urban site might be attributable to regional stressors, such as climate change or atmospheric deposition of nutrients, rather than to management activities.

Methods

Data Collection

Data were collected as described in the Survey Overview.

Data Aggregation

Where multiple samples were collected at a single site within a year, data were aggregated as the maximum value within a site. Missing values were ignored for all relevant analyses, where appropriate.

Thresholds

Thresholds were applied as described in the section on Question 1.

Weighted Magnitudes and Extent Estimates

Weighted estimates were calculated as described in the section on Question 1, using each year (or year within land use class) as a stratum. Extents of streams in each condition class were estimated for the CSCI, S2, D18, and CRAM. In addition, the extent of streams intact for all indicators was estimated as well.

Results

All data used in this report can be downloaded from <ftp.sccwrp.org/pub/download/SMCReport/SMCDataFor5yearReport.zip>.

Since 2009, no obvious trends were evident for any indicator, although all indicators showed a slight depression in scores in the year 2010 (Tables 3-1 and 3-2; Figure 3-1). The median score for the CSCI, S2, and CRAM fluctuated between Class 2 and 3, while D18 fluctuated between Class 3 and 4. The percent of streams that were intact for all four indicators was highest (at 36%) in 2012, but was only 14% in 2010 (Figure 3-2). Most of the fluctuations in score affected the open streams, while the extent of healthy agricultural and urban streams remained low throughout the survey (Table 3-1, 3-2). Extent estimates were particularly imprecise for agricultural streams, as in some years very few of these sites were sampled (e.g., 5 agricultural sites were sampled for all indicators in 2011 and 2012), leading to erratic confidence intervals

(Figure 3-1). Although CSCI scores were generally high in the earlier years of the survey, these estimates were based on very small sample sizes (<25 sites in any year), and should be interpreted with caution.

Discussion

We were unable to detect trends in condition. Our inability to detect trends stems from the relatively short time frame of the survey (i.e., 5 years), as well as a study design that did not include site revisits over multiple years. These two characteristics of the survey make it difficult to distinguish trends from natural variation driven by climate or other factors. Given that a different set of sites was examined each year, the regional focus of the program, and that only five years of data are presented, it is not surprising that no distinct trends were observed. For a trend at this regional scale to be evident, a longer time period would be required and/or site revisits. It is possible that site-specific management activities affecting stream health were within the sample frame, but may have been obscured by the overall regional focus. Revisiting sites sampled in early years of this survey would provide site-specific trend estimates, which could then provide a better estimate of trends across the region. Additionally, we would be able to explore potential drivers of any observed trends.

Multiple indicators	1	4	0	1	3

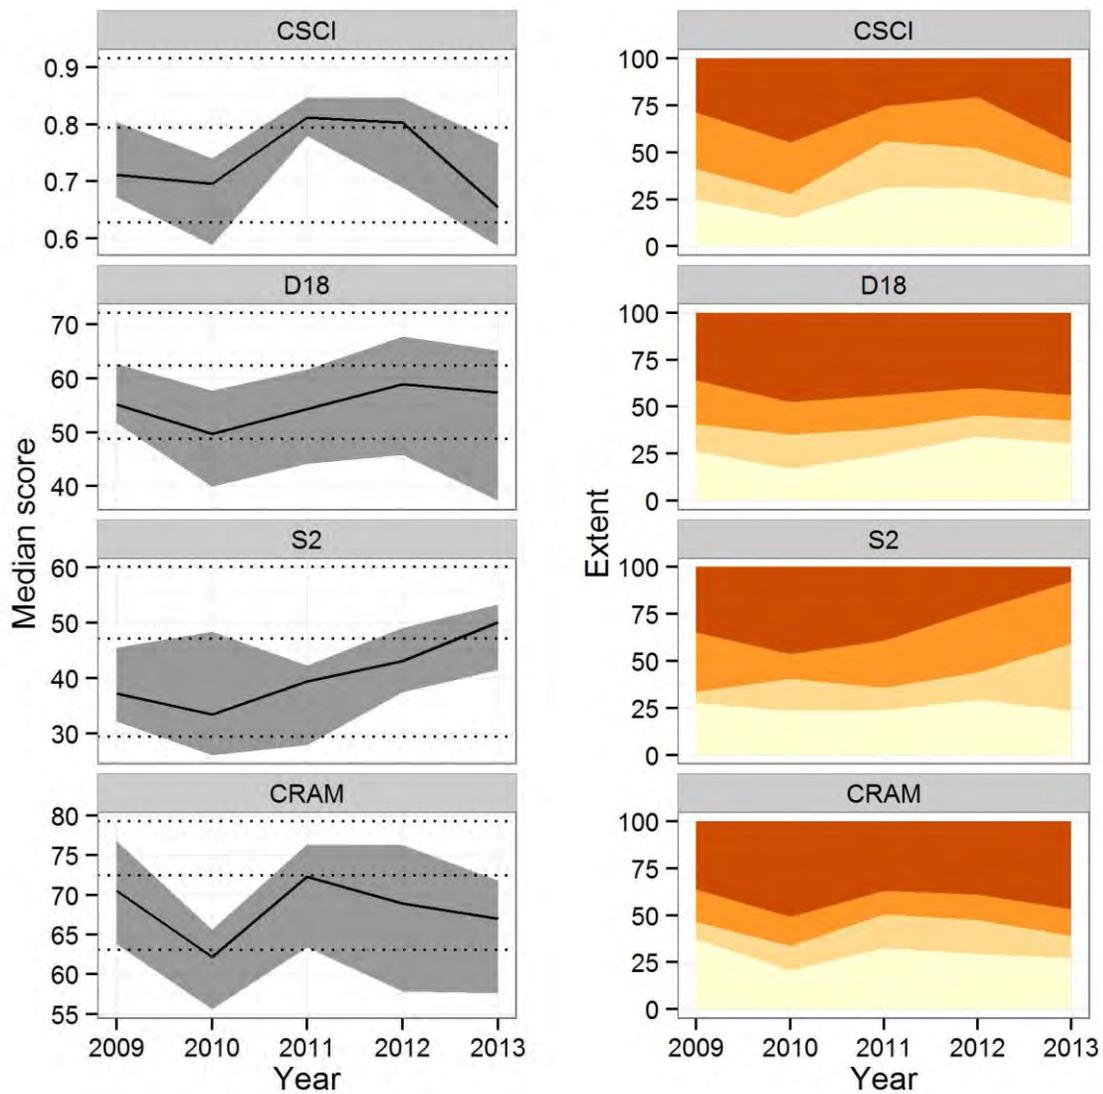

Figure 3-1. Median score and extent of condition classes by year for each indicator. The gray band in the left panel indicates the 95% confidence interval. Color in the right panel indicates condition class; lighter colors indicate better condition.

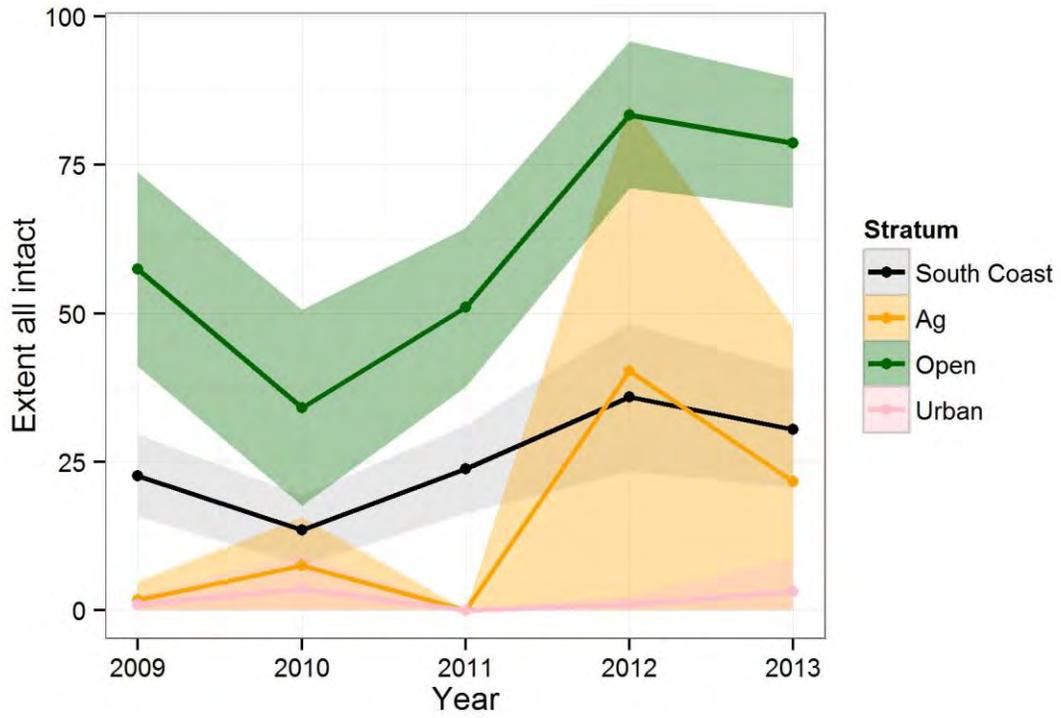

Figure 3-2. Percent of stream-miles that were intact for all four indicators

RECOMMENDATIONS

- Continue the survey for another five years, focusing on key biological indicators of stream condition, as well as high-priority stressors.
- Expand the survey to include nonperennial streams.
- Improve trend estimates by revisiting previously sampled probabilistic sites.
- Continue to investigate high priority stressors, such as habitat degradation and nutrient enrichment.
- Support studies that identify constraints on biological condition imposed by natural factors, channel engineering, water chemistry, and habitat degradation.

Total employment, percent change, 2014-2015	2.2%
Total nonemployer establishments, 2015	67,736
All firms, 2012	76,285
Men-owned firms, 2012	39,995
Women-owned firms, 2012	26,682
Minority-owned firms, 2012	25,161
Nonminority-owned firms, 2012	48,210
Veteran-owned firms, 2012	5,861
Nonveteran-owned firms, 2012	67,137
 GEOGRAPHY	
Geography	
Population per square mile, 2010	446.7
Land area in square miles, 2010	1,843.13
FIPS Code	06111

Value Notes

 This geographic level of poverty and health estimates is not comparable to other geographic levels of these estimates

Some estimates presented here come from sample data, and thus have sampling errors that may render some apparent differences between geographies statistically indistinguishable. Click the Quick Info  icon to the left of each row in TABLE view to learn about sampling error.

The vintage year (e.g., V2016) refers to the final year of the series (2010 thru 2016). Different vintage years of estimates are not comparable.

Fact Notes

- (a) Includes persons reporting only one race
- (b) Hispanics may be of any race, so also are included in applicable race categories
- (c) Economic Census - Puerto Rico data are not comparable to U.S. Economic Census data

Value Flags

- Either no or too few sample observations were available to compute an estimate, or a ratio of medians cannot be calculated because one or both of the median estimates falls in the lowest or upper interval of an open ended distribution.
- D Suppressed to avoid disclosure of confidential information
- F Fewer than 25 firms
- FN Footnote on this item in place of data
- NA Not available
- S Suppressed; does not meet publication standards
- X Not applicable
- Z Value greater than zero but less than half unit of measure shown

QuickFacts data are derived from: Population Estimates, American Community Survey, Census of Population and Housing, Current Population Survey, Small Area Health Insurance Estimates, Small Area Income and Poverty Estimates, State and County Housing Unit Estimates, County Business Patterns, Nonemployer Statistics, Economic Census, Survey of Business Owners, Building Permits.

ATTACHMENT 66

Mobile Detailers

Do you know where the water goes?

The "DON'T DUMP !" signs are placed next to storm drains to remind everyone that gutters and storm drains carry rain as well as any pollutants directly to arroyos, creeks and the ocean without any treatment.

Disposing of cleaning solutions or soapy water into gutters and storm drains can harm or kill wildlife, even if it's labeled nontoxic or biodegradable. Wastewater from vehicle and equipment cleaning needs to be treated. This can be accomplished by natural filtration or

- Only Wash in Specially Designated Areas. Washing vehicles and equipment outdoors or in areas where wash water flows onto paved surfaces or drainage areas can pollute the storm drain system.
- Vacuum up any Remaining Wastewater.
- Pay Close Attention to the Amount and Type of Chemicals You Use. Never use engine degreasers or toxic wheel cleaners. These products typically contain petroleum based solvents and may be highly corrosive.
- If You Must Use a Detergent, make sure it is Phosphate Free and Biodegradable. It is a common misconception that a phosphate free, biodegradable detergent is completely safe for the environment. Any detergent can impact the environment. Many professional auto detailers do not use detergents.
- Use as Little Water as Possible. Limiting the amount of wash and rinse water reduces the possibility of wastewater runoff. Unpermitted wastewater discharges are prohibited by local ordinance.
- Don't let the Wash or Rinse Water Run Off the Site!

Pollution Fact Sheet/Business - Vehicle / 1999

Washing Your Vehicle

Do you know where the water goes?

The "DON'T DUMP !" signs are placed next to storm drains to remind everyone that gutters and storm drains carry rain as well as any pollutants directly to arroyos, creeks and the ocean without any treatment.

Washing vehicles and equipment outdoors where wash water flows onto paved surfaces or disposing of cleaning solutions or soapy water into gutters and storm drains can pollute and harm or kill wildlife, *even if the cleaning solution is labeled nontoxic or biodegradable.*

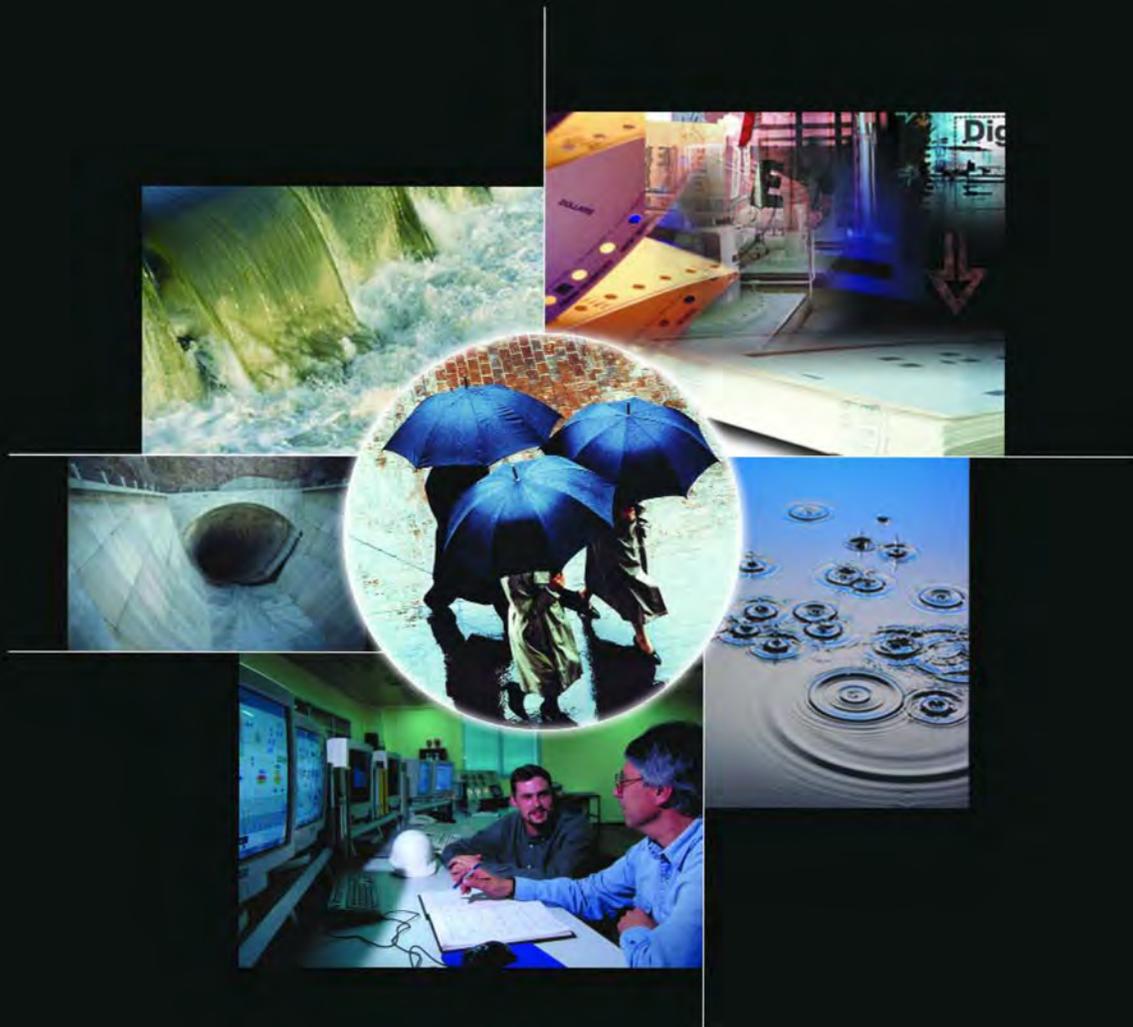

- Why not use a Commercial Car Wash? Commercial car washing facilities are designed to re-use water whenever possible and discharge any wastewater into the sanitary sewer, where it is treated before being discharged to the environment. Whenever possible, take your car to a self or full serve commercial car wash.
- Pay Close Attention to the Amount and Types of Chemicals You Use. Never use engine degreasers, tar removers, or toxic wheel cleaners. These products typically contain petroleum based solvents and may also be highly corrosive. They can create safety hazards for both the environment and for human health. Read the label when you purchase any cleaning product and buy the least hazardous product to protect you, your car, and your family.
- If you must use Detergent, make sure it is Phosphate Free and Biodegradable. It is a common misconception that a phosphate free, biodegradable detergent is completely safe for the environment. Any detergent can impact the environment.
- Use as Little Water as Possible. Don't let your garden hose run when you are not using it. Remember, the more clean water you use, the more wastewater you generate.
- Don't let Wash or Rinse Water Run Off the Site!

Pollution Fact Sheet/General Public - Vehicle / 1999

2005 STORMWATER UTILITY SURVEY

BLACK & VEATCH
building a **world** of difference™

ENERGY WATER INFORMATION GOVERNMENT

Black & Veatch is pleased to provide the results of its sixth national Stormwater Utility Survey, to help those involved in the stormwater industry stay well-informed across a range of issues. The survey results offer insight into the following topics:

- Organization/Administration
- Planning
- Operations
- Finance/Accounting
- Stormwater User Fees and Billing
- Quality Issues – Best Management Practices
- Public Information/Education
- Major Challenges Recently Faced
- Significant Events Affecting Utilities

These results can be used for numerous purposes, from performance management to financial planning to organization strengthening. At Black & Veatch, we understand the value of knowing what others are doing in the industry. For 90 years, meeting the needs of the utility industry has been at the core of our business. We are happy to discuss any questions you might have regarding this survey.

Profile of Respondents

- Responses were received from 99 utilities in 21 states and one Canadian province. All of these utilities are funded in whole or in part through user fees.
- Approximately 86 percent of the respondents serve a city, rather than a county or region.
- The population served by the respondents ranges from 1,400 (Atlantic Beach, FL) to 3.9 million people (Los Angeles, CA) and the area served varies from 3 to 1,500 square miles. Eighty-one percent indicate they are responsible for stormwater facilities only, while the balance report they are responsible for combined sanitary/stormwater facilities. Approximately 88 percent indicate that they use their own staff to provide a majority of operation and maintenance services.
- For those utilities that base charges on gross property area, equivalent residential units ranged from 1,600 square feet total area to 11,000 square feet, with a mean of 6,964 square feet. For those utilities that base charges on impervious area, impervious areas per equivalent residential unit ranged from 1,500 square feet to 10,000 square feet, with a mean of 2,647 square feet.

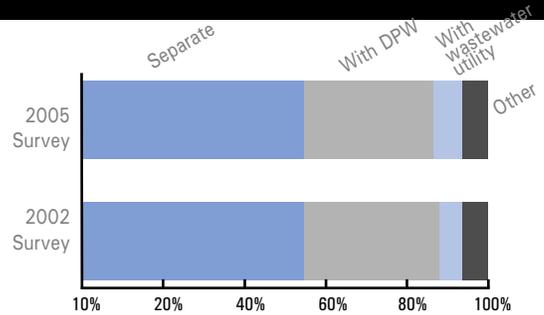

What's New

Feedback from participants prompted us to add a new question to the 2004-2005 version of the Stormwater Utility Survey. In recent years, a number of stormwater treatment systems have become commercially available. Fifty-six percent of respondents have installed at least one of these devices with the most popular being Stormceptor, StormFilter, and CDS Separator. Thirty-six percent have had a favorable experience with these devices in terms of treatment efficiency and ease of maintenance, while 41 percent are still in the evaluation process.

Organization / Administration

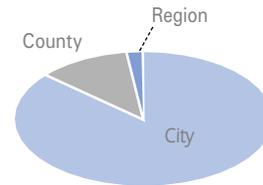

Q How is your operation organized?

- 55% Separate utility
- 32% Combined with Department of Public Works
- 7% Combined with wastewater utility
- 6% Other

Q What area does your utility serve?

- 86% Within city limits
- 12% County
- 2% Region

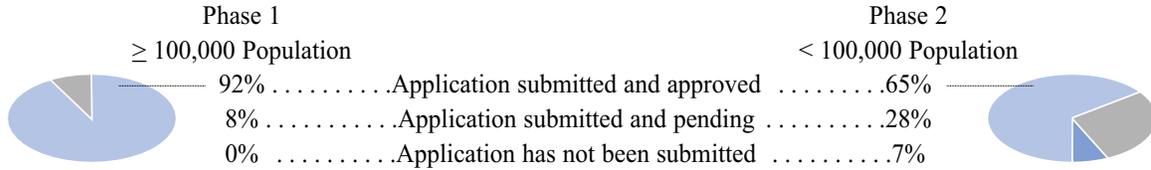

Q Does your state have specific statutes that govern the formation of stormwater utility and user fee financing?

- 71% Yes
- 29% No

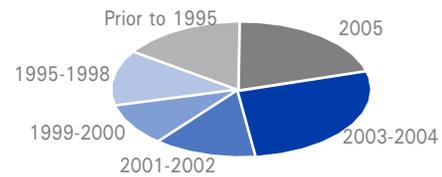

Planning

Q What is the status of your NPDES permit?

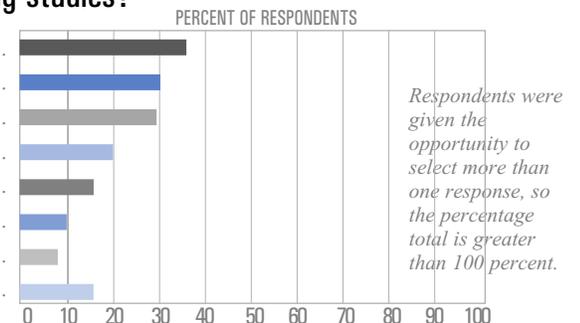

Q When was your most recent stormwater plan or stormwater facilities plan?

- 21% 2005
- 27% 2003–2004
- 13% 2001–2002
- 10% 1999–2000
- 13% 1995–1998
- 16% Prior to 1995

Q What stormwater computer models do you use for planning studies?

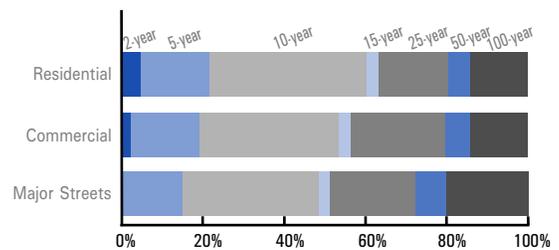

- 36% HEC-2
- 30% XP-SWMM
- 29% HEC-1
- 20% TR-55
- 16% EPA SWMM
- 10% HEC-RAS
- 7% HEC-HMS
- 15% Other

Planning (continued)

Q What return periods do you use to design your major stormwater structures?

	Residential	Commercial	Major Streets
2-year	3%	1%	0%
5-year	18%	17%	14%
10-year	39%	35%	34%
15-year	3%	3%	3%
25-year	17%	23%	21%
50-year	6%	7%	8%
100-year	14%	14%	20%

Several respondents provided a range of return period. The percentages above represent the smallest return period provided.

Q Which performance indicators do you consider most important in measuring improvement in stormwater management success?

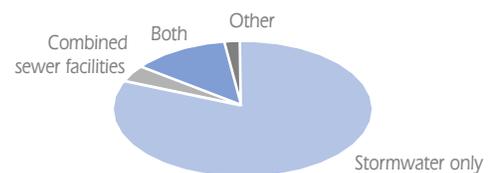

47%	Flood control
31%	Monitoring pollutants
17%	Customer complaints/satisfaction
11%	Cost control measures
6%	Erosion control
6%	Maintenance
5%	Habitat

Operations

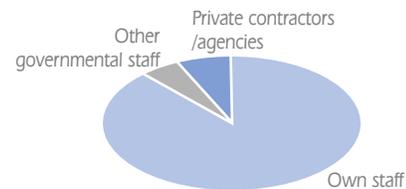

Q What is your utility responsible for?

81%	Stormwater facilities only
4%	Combined sewer (sanitary/stormwater) facilities
13%	Both
2%	Other

Q Who provides the majority of your O&M services?

88%	Own Staff
5%	Other Governmental Staff
7%	Private contractors/agencies

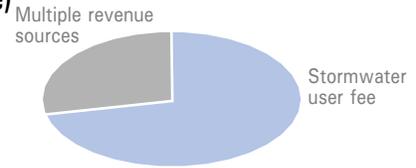

Finance/Accounting

Q What are your major (at least 90 percent of total income) revenue sources?

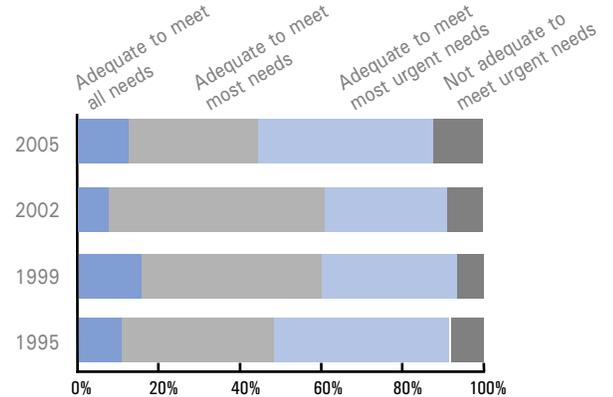

(Excludes 7 utilities that reported no single major source)

- 72% Stormwater user fee
- 28% Multiple revenue sources

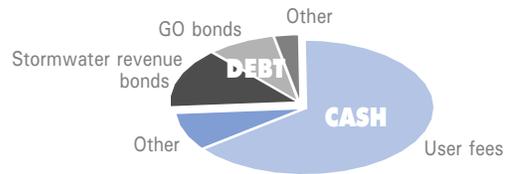

Q How adequate is available funding?

- 13% Adequate to meet all needs
2002 = 8% • 1999 = 16% • 1995 = 11%
- 32% Adequate to meet all needs
2002 = 53% • 1999 = 44% • 1995 = 38%
- 43% Adequate to meet most urgent needs
2002 = 30% • 1999 = 34% • 1995 = 44%
- 12% Not adequate to meet urgent needs
2002 = 9% • 1999 = 6% • 1995 = 7%

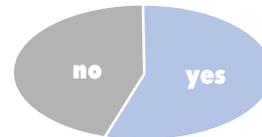

Q How is the majority of capital improvement needs financed?

- 74% Cash financed
 - 65% From user fees
 - 0% From ad valorem taxes
 - 9% Other
- 26% Debt financed
 - 14% Stormwater revenue bonds
 - 9% General obligation bonds
 - 0% Combined bonds
 - 3% Other

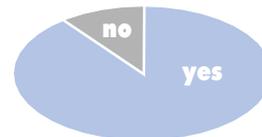

Q Does your accounting system permit cost tracking by operating activity (e.g., inlet cleaning)?

- 55% Yes
- 45% No

Q Does your accounting system identify user fee revenues by customer class (e.g., residential)?

- 89% Yes
- 11% No

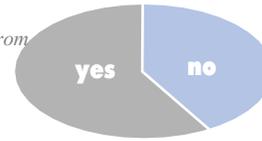

Stormwater User Fees and Billing

Q Were your rates revised in the last 12 months?

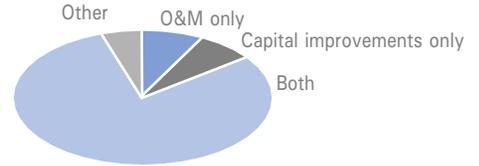

- 41% No
- 59% Yes

Increases ranged from 1% minimum to 117% maximum

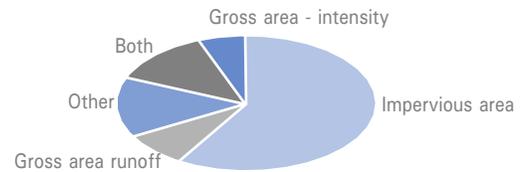

Q What are your user fees designed to pay for?

- 8% Operation and maintenance (O&M) expenses only
- 7% Capital improvements only
- 80% Both O&M expenses and capital improvements
- 5% Other

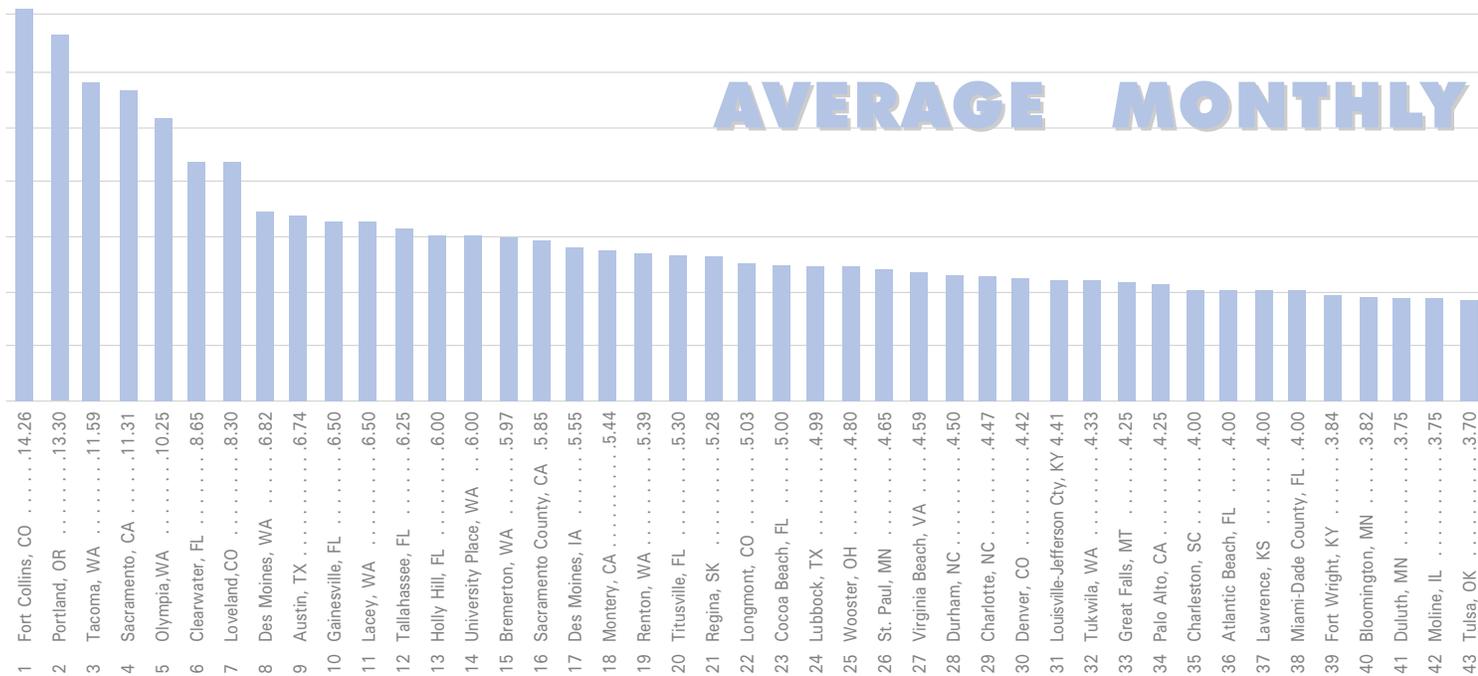

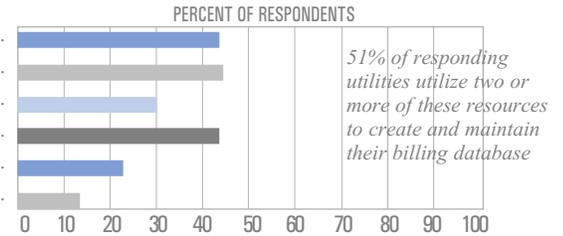

Q What is the basis for your user fees?

- 59% Impervious area
- 8% Gross area with intensity of development factor
- 14% Both impervious and gross areas
- 13% Other (e.g., number of rooms, water use, flat fee)
- 6% Gross area with runoff factor

Q If user fees are area-based, what principal resources were employed to create and maintain the customer database used to compute charges?

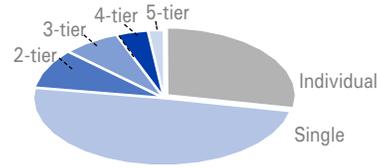

- 42% Property tax assessor records
- 43% Aerial photographs
- 29% On-site property measurement
- 42% Geographic Information System (GIS)
- 22% Planimetric map take-offs
- 13% Other (e.g., building permits, site plans)

Q Are your stormwater charges based on individual or class average characteristics?

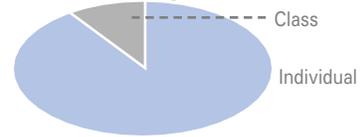

Residential

- 27% Individual parcel
- 73% Class average as:
 - 48% Single tier
 - 9% 2-Tier rate
 - 7% 3-Tier rate
 - 4% 4-Tier rate
 - 2% 5-Tier rate

Non-Residential

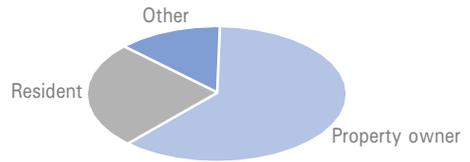

- 90% Individual parcel
- 10% Class average

3% of respondents who answered class average did not provide the number of rate tiers.

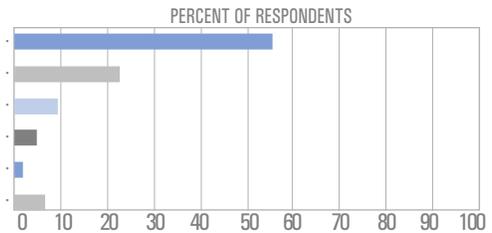

Q Who is responsible for the payment of user fees?

- 62% Property owner
- 25% Resident
- 13% Other (e.g., water or other utility bill recipient)

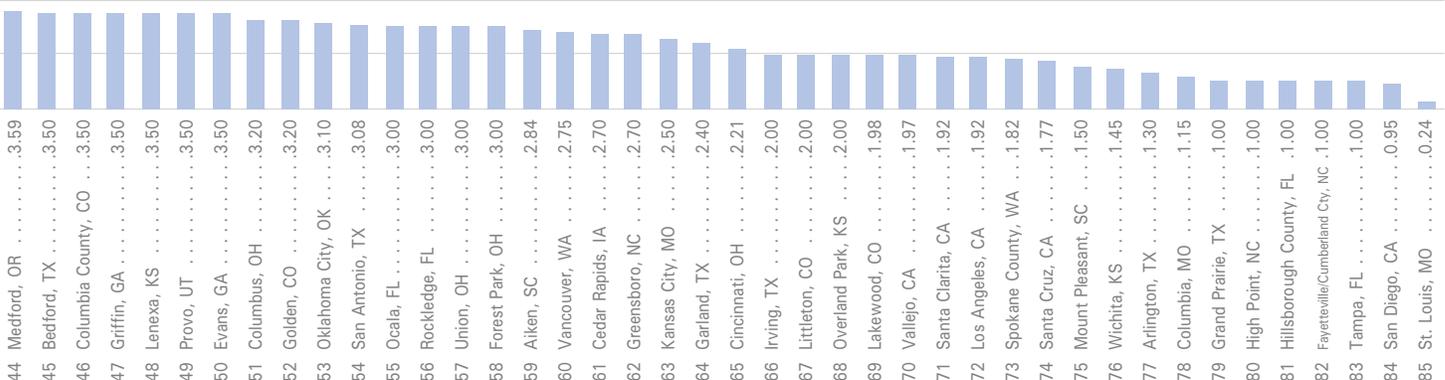

Q How frequently do you bill?

- 56% Monthly
- 22% Annually
- 9% Bi-monthly
- 5% Quarterly
- 2% Semi-annually
- 6% Other

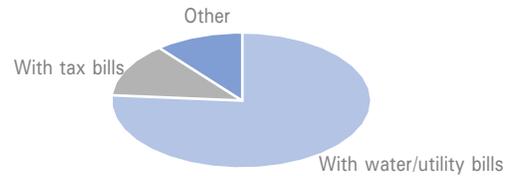

RESIDENTIAL CHARGE

Stormwater User Fees and Billing (continued)

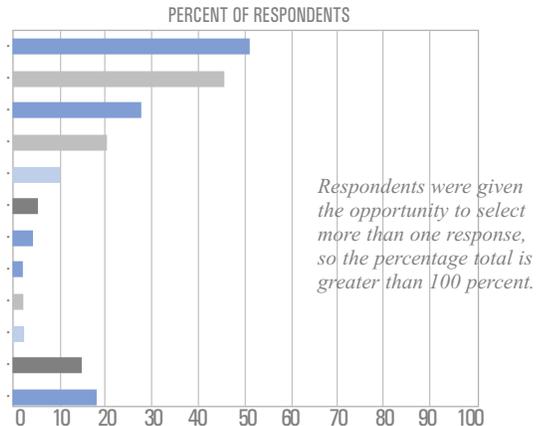

Q How are your user fees billed?

- 76% With water or other utility bills
- 13% With tax bills
- 11% Other

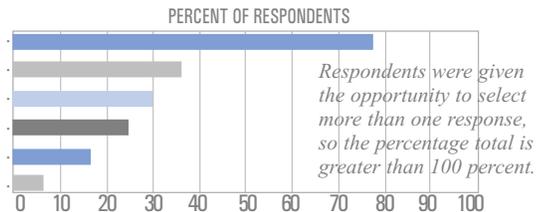

Q What types of properties are exempt from user fees?

- 51% Streets/highways
- 46% Undeveloped land
- 27% Rail rights-of-way
- 20% Public parks
- 10% Government
- 5% School districts
- 4% Churches
- 2% Airports
- 2% Colleges/universities
- 2% Water front
- 14% None
- 17% Other

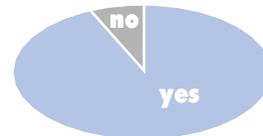

Q What customer classifications are recognized in your stormwater fee structure?

- 77% Residential
- 36% Commercial
- 30% Combined commercial/industrial
- 25% Other
- 17% Industrial
- 7% No designation

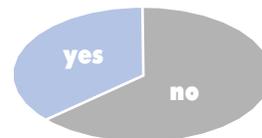

Q Are rates the same for all service areas or watersheds?

- 93% Yes
- 7% No

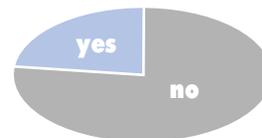

Q Are your user fees for single family dwellings the same as for individual multiple residential units, such as apartments and condominiums?

- 64% No
- 36% Yes

Q Are one-time impact/capital recovery fees applied to new stormwater utility customers or new development?

Major Challenges Recently Faced

Financial, rate, and billing related issues (e.g., financing growth, capital replacements, NPDES and other environmental mandates; rate increases, rate equitability, rate challenges; and billing database updating or conversion to GIS)	19 utilities
Weather and flooding issues (e.g., high amounts of rainfall, standing water, West Nile concerns, localized flooding)	10 utilities
Erosion control (e.g., run-off, erosion problems)	8 utilities
Regulatory and quality control compliance (e.g., illicit discharges, quality monitoring, and difficulties of complying with more stringent state and federal quality mandates related to Endangered Species Act, TMDLs, et al.)	8 utilities
Infrastructure planning issues (e.g., need for integrated flood, quality and environmental planning; remedy of specific infiltration/inflow or local flooding problems; and system-wide flood control master planning)	7 utilities
Jurisdictional issues (e.g., incorporation of added cities into service area and co-permittee coordination)	3 utilities
Public education (e.g., need for increased education regarding new programs or rate increases)	2 utilities

Significant Events Affecting Utilities in Past Two Years

NPDES compliance	21 utilities
CIP related (funding, projects started/completed)	14 utilities
User fee related (increases, lack of increases)	14 utilities
Weather related (heavy rains, storms, drought)	8 utilities
Organization/administration/staffing changes	7 utilities
Public education/awareness	4 utilities
Urban growth/decline in service area	4 utilities
Legal challenges	2 utilities

Some respondents listed the same events as positive, negative, or both (e.g., heavy rains or flooding brought both damage and increased public awareness of needs).

Stormwater Management

From run-off to potential revenue stream, stormwater management is uniquely challenging. It is often not source-specific, not metered or monitored closely within the community, and not tied to customers' daily decisions.

Black & Veatch's Enterprise Management Solutions team assists utilities nationwide in stormwater management issues to help provide stable funding for operations as well as capital projects.

ABOUT ENTERPRISE MANAGEMENT SOLUTIONS

Black & Veatch is pleased to provide this survey as an industry service. For 90 years, meeting the needs of utilities nationwide has been at the core of our business. We understand the value of knowing how others are addressing the industry's complex issues. From organization effectiveness to financial structuring to risk management, it helps to know the industry's trusted business partner. Black & Veatch brings it all together.

2010/2011**

FOREWORD

the Benefit Assessment Program to finance their respective activities related to reducing the discharge of storm water pollutants, which will result in a substantial impact to fiscal resources levied through the Benefit Assessment Program.

In addition, a portion of the benefit assessment monies collected each year are held in reserve in case of future disaster. Floods, wildfires, erosion, and mud/debris flows all have the potential to cause extensive damage to District facilities. While a Presidential disaster declaration makes federal and State relief monies available for the repair and restoration of existing facilities and for mitigation measures to avoid future damage, significant District resources are required as local match. Funds held in reserve ensure that the District has the resources necessary to quickly recover from a disaster.

This report describes the District's Benefit Assessment program for FY 2010-11. It contains a description of the mechanics of calculating fees and defines the manner in which fee revenue may be spent and, by reference, includes the official benefit assessment roll as approved by the District's Board of Supervisors. A serious disparity continues to exist between revenues and the cost of operations and maintenance of flood mitigation facilities. Continued shortfalls in revenue required the Ventura County Watershed Protection District's Benefit Assessment Program be continued for fiscal year 2011.

I. EXECUTIVE SUMMARY

I. EXECUTIVE SUMMARY

The Ventura County Watershed Protection District Benefit Assessment (BA) Program is authorized by the Ventura County Watershed Protection District Act, as amended by Chapter 438, Statutes of 1987 and Chapter 365, Statutes of 1988. The FY2011 Benefit Assessment for Watershed Protection is based on the rates established for Fiscal Year 1997. Those same rates were approved for Fiscal Years 1998-1999 through 2009-2010. They were approved again in compliance with Proposition 218 on June 08, 2010 for fiscal year 2010-2011.

This Report presents the continuation of the BA Program to supplement insufficient existing revenues for financing routine operation and maintenance of District facilities and the Countywide Stormwater Quality Management Program. Additionally, this report outlines the benefit assessment component that sets aside reserve funds in Zones 1, 2, and 3 for flood damage repair.

The population of Ventura County has increased from approximately 200,000 people in 1960 to about 792,313 in 2010², a figure that may climb to over 874,000 by 2015³. The growth associated with this projected population increase will result in additional impervious surfaces and increased runoff. There will likely be pressures to locate new developments in flood hazard areas. New watershed protection facilities constructed by developers and the District will be required, and the subsequent increases in maintenance costs will tax already limited revenues.

Due to the unpredictable nature of the winter weather in Ventura County and frequently experienced flood damage, periodic increases in assessments have been necessary to cover the cost of damage repair. Between 1988 and 1995, three temporary assessment increases were levied to cover shortfalls in O&M funding and State and Federal reimbursements.

In June 1995, a Flood Damage Repair Reserve was established as a precautionary measure to fund future emergency repairs. The intent was to offset future flood damage repair costs while minimizing the fluctuations in BA rates. Due to the magnitude of the 2005 federally declared disaster, all Flood Damage Repair funds were exhausted before June 30, 2005 for necessary repairs. Replenishment of this Reserve component will ensure that the District has funds available to repair damaged facilities and to implement mitigation measures in a timely manner.

In addition, water quality plays an important role in Ventura County, with its 42 miles of coastline and three major watersheds (Calleguas Creek, Santa Clara River, and Ventura River). Each river system within the county represents an important resource for recreation, water supply and natural habitat. The State of California has required, through an NPDES Permit, the programs to protect the water quality in these watersheds and provide for water quality monitoring. That responsibility lies with the Ventura Countywide Stormwater Quality Management Program. The program represents a joint effort between the District, the County of Ventura, and the Cities of Camarillo, Fillmore,

2. http://www.dof.ca.gov/research/demographic/documents/ACS2009_05_STCOPL_Extract.xls

3. <http://www.ventura.org/rma/planning/pdf/demographics/VCOG/pop.pdf>

Moorpark, Ojai, Oxnard, Port Hueneme, San Buenaventura, Santa Paula, Simi Valley, and Thousand Oaks.

The ultimate goal of the program, which is funded in part with BA monies, is to reduce pollutants in the waters of Ventura County to the maximum extent practicable.

With the issuance of a third term NPDES Permit on May 7, 2009, there have been substantial increases to permit requirements. Some of the more significant additional requirements include inspection of industrial facilities, inspection of construction sites and far more expansive water quality monitoring. Even with these additional requirements there has been no increase to the Benefit Assessment rate.

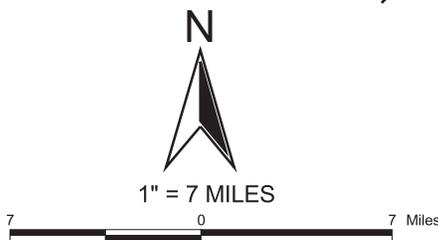

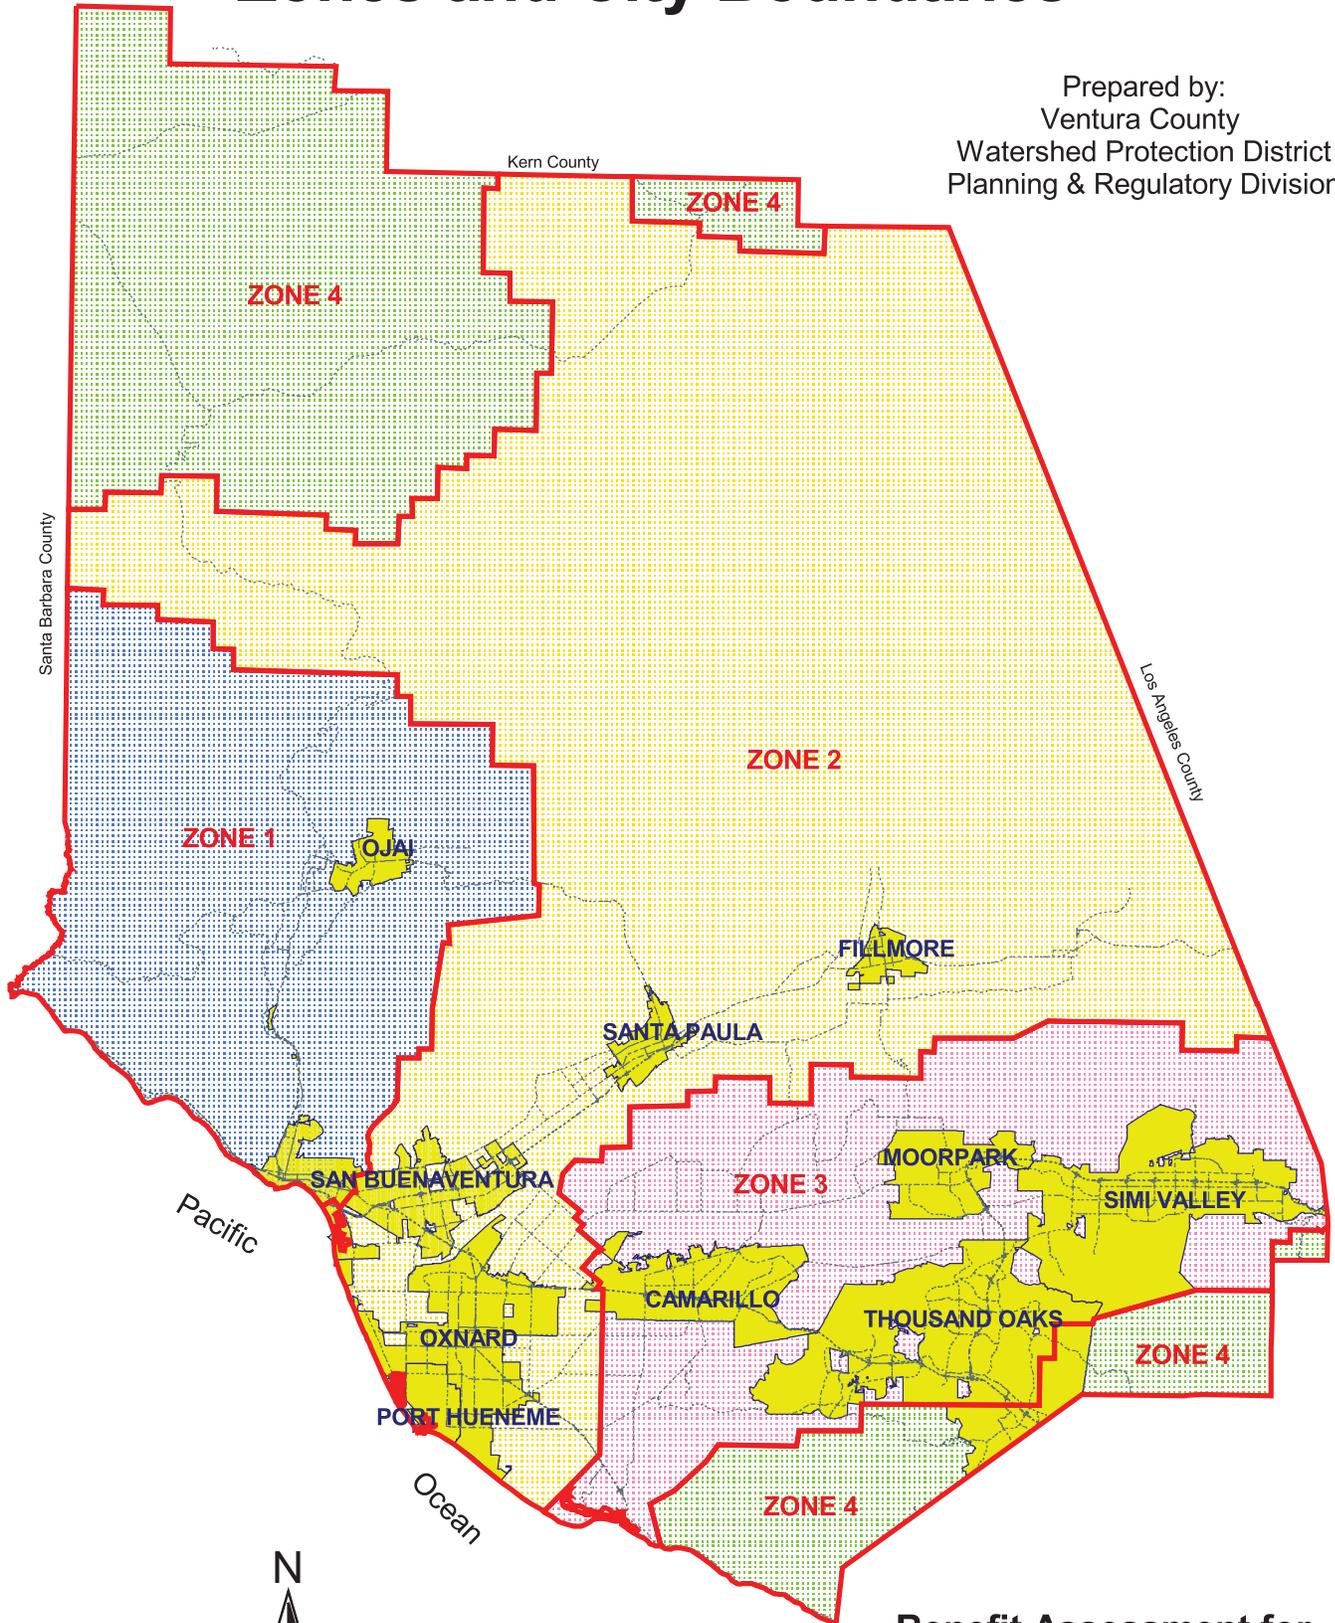

This Report on BA Program for Watershed Protection contains the following:

A "needs assessment" which provides a cost/revenue analysis outlining the financial need for a benefit assessment program and describes existing and potential District facilities and services to be financed with BA revenues

- An extensive discussion of the existing BA Program methodology and formulas used in determining assessments.
- Assessment formula and impervious factors relating to assessor site use codes (Appendix A)
- Assessment Roll for FY 2011, as approved by the County of Ventura Board of Supervisors, including the parcel number and amount of assessment for each parcel (Appendix B available in digital format under separate cover)
- Resolutions approved for FY 2011 by various City Councils (Appendix C - available under separate cover)

**Benefit Assessment for
Flood Control
Fiscal Year 2010-2011
Figure 1**

II. BACKGROUND

II. BACKGROUND

The Ventura County Flood Control District was created September 12, 1944, when the California Legislature approved the Ventura County Flood Control Act. The District was formed, in part, to control and conserve flood and storm waters and to protect watercourses, watersheds, public highways, life and property from damage because of those waters. Over the years, the Flood Control Act has been amended to reflect the paradigm of the times, adding provisions for recreational use, scenic beauty, the enhancement, protection and preservation of the natural environment, and benefit assessment.

Once dominated by agriculture, Ventura County is now the 11th most populous county in California and home to more than 792,313 people. As land has been transformed into cities, it has become increasingly important to control floodwaters. Communities look to the District to protect their homes, businesses, and farmlands from devastating floods, while preserving water quality, safeguarding habitat and improving creek aesthetics.

On September 14, 2002, then Governor Gray Davis signed AB2320 (Strickland), changing the name of the District to the Ventura County Watershed Protection District, and the name of existing law to the Ventura County Watershed Protection District Act. The name change, effective January 1, 2003, represents the culmination of an evolution in the District's mission, community values, regulatory requirements and funding opportunities.

Authority to implement a BA Program is established by the Ventura County Watershed Protection District Act (Chapter 46 of the Water Code Appendix, as amended) and by California Government Code Section 54710. Other pertinent legal requirements are defined in California Government Code Sections 54711, 54715 and 54716.

On July 15, 1980, the District Board of Supervisors approved the Flood Control Benefit Assessment Ordinance (FC-26), that allows for the establishment and levy of benefit assessments to pay for the costs of providing flood control services in Zones 1, 2, 3 and 4. The Ventura County Watershed Protection District BA Program was subsequently established by the District Board of Supervisors on June 14, 1988, establishing the first assessment rates in each of the District's four zones for Fiscal Year 1988-89. In each subsequent year, the District Board of Supervisors has resolved to continue the District BA Program.

Originally established to finance the rising costs of operations and maintenance of District facilities in each zone, the BA Program has been expanded over the years to provide needed revenues for emergency flood damage repair costs from the flood disasters of 1995, 1998, and 2005, for instance, and also to establish a flood damage repair reserve, and to implement the National Pollutant Discharge Elimination System stormwater program.

As a primary component of the 1972 Federal Clean Water Act, Congress established the National Pollutant Discharge Elimination System (NPDES) permit program to control water pollution by regulating the discharge of pollutants to the surface waters of the

United States. The NPDES permit program initially regulated wastewater discharges of industrial process water and wastewater from sewage treatment plants. However, in 1987, the Clean Water Act was amended to include NPDES permit requirements for the discharge of stormwater from publicly owned municipal storm drains.

In response to those requirements, on August 22, 1994, the Los Angeles Regional Water Quality Control Board issued the Ventura County Watershed Protection District (as Principal Permittee), the County of Ventura, and the Cities of Camarillo, Fillmore, Moorpark, Ojai, Oxnard, Port Hueneme, San Buenaventura, Santa Paula, Simi Valley and Thousand Oaks (as Permittees) a five-year term countywide NPDES permit for discharges from publicly owned municipal storm drains in Ventura County. The first-term permit was educational in nature and emphasized agency staff training and outreach efforts to inform the public about storm water quality concerns. On July 27, 2000, a second five-year term countywide permit was issued to the Permittees. The second-term permit was more enforcement oriented and emphasized inspection related activities, compliance documentation, and monitoring.

On May 7, 2009 the Los Angeles Regional Water Quality Control Board adopted a new NPDES permit (Order Number 09-0057) (Permit) for the discharge of stormwater from Ventura County's municipal separate storm drain systems. The third-term Permit was effective on August 5, 2009. The LA Water Board Permit voluntarily remanded and reissued the Permit on July 8, 2010 as NPDES Permit No. CAS004002/Order No. 10-108 (Permit). This Permit became immediately effective upon adoption and is also considered the third term Permit.

The Permit designated the Watershed Protection District (District) as the Principal Permittee and as such the District has specific responsibilities including countywide program coordination, water quality monitoring, preparation and submittal of reports and public outreach.

The District, as Principal Permittee, has taken the lead in the development of an integrated Countywide Stormwater Quality Management Program. Since its inception, the Stormwater Quality Management Program has been financed through the District's BA Program. Implementation Agreements (dated June 30, 1992) between the District and the other Permittees (Cities and County of Ventura) provide for the structure that allows for the County and the Cities to utilize BA funds to finance NPDES related activities.

The additional program cost for the Principal Permittee as well as the Permittees associated with the 2010 NPDES Permit has prompted further effort among the Permittees to equitably share the increased costs. The result of that effort was the drafting of a new Implementation Agreement in 2010.

The Agreement defines the fiscal responsibilities (expenditures and contributions) of all collective parties with respect to the current Permit. It formalizes the Permittees' commitment to cooperate and to mutually fund an integrated Program of protecting and improving water quality in Ventura County. This Agreement allows for a sharing of Principal Permittee costs among all the Permittees, and replaces the original 1992 NPDES

Implementation Agreement for five years. At that time a new agreement will be adopted or the original 1992 NPDES Implementation Agreement will become effective again.

Assessments are levied based on the proportion of stormwater a parcel of land contributes to the overall stormwater runoff. This funding mechanism has allowed the Permittees to utilize a stable, flexible, and equitable program to pursue stormwater management goals and improve water quality countywide. Prior to the passing of Proposition 218 in 1998, NPDES BA rates were adjusted according to fund reserves and projects required by the permit. However, Proposition 218 prohibited rate increases without majority approval from property owners.

With the issuance of a third term NPDES Permit on July 7, 2010, there have been substantial increases to permit requirements. Some of the more significant additional requirements include inspection of industrial facilities, inspection of construction sites and far more expansive water quality monitoring. Other significantly affected programs include land development, illicit discharge and illicit connection investigation, storm drain mapping and water quality monitoring and reporting. Additionally, Total Maximum Daily Loads (TMDLs), strict levels of pollutants that can enter a waterbody without impairing that water's beneficial uses, will become enforceable under the Permit.

In addition to responding to reports of illicit discharges and connections, the Permit also requires field screening of storm drains for evidence of polluting activities. Analytical monitoring of urban areas is also increased with a major outfall in each Permittees' jurisdiction to be sampled. The result of that monitoring will be used to determine if the discharge is causing or contributing to water quality exceedances in the receiving water.

Significant new development and redevelopment projects are required to implement Low Impact Development (LID) concepts. The main tenet of LID is for developments to disconnect impervious surfaces (e.g., parking lots and rooftops) from the storm drain systems by providing for onsite infiltration and/or retention. The Permit sets a strict limit of allowing only 5% of a project area to drain off a site unless technical infeasibility can be demonstrated. Projects with technical infeasibility are allowed to use biofiltration, and certain types of projects with technical infeasibility are allowed offsite alternative compliance mitigation. All stormwater draining from new development and significant redevelopment will still need to be treated to remove pollutants, and new performance standards will be used to select the appropriate treatment.

The following are planned in 2011:

- Implementation of the revised Technical Guidance Manual for Stormwater Quality Control Measures. The Technical Guidance Manual is guide for future new development and redevelopment to comply with the low impact development Permit requirements. To facilitate the implementation special training for Permittee staff and the public is planned.
- Development of an offsite alternative compliance mitigation program with an integrated water resource management approach that also considers flood

protection surface water impairments, seawater intrusion, groundwater recharge, and potential water reuse through water banking.

- Implementation of the Youth Outreach Plan and a general public outreach campaign to change behaviors that contribute to stormwater pollution.
- Development of new monitoring procedures and the sampling of river sediment for pyrethroid pesticides, which is an emerging pollutant introduced to replace recently banned pesticides.
- Continuation of the Regional Bioassessment Program to assess the overall health of Southern California streams.
- Development of a new Electronic Annual Report format to show compliance with the Permit and Improve program effectiveness.

This report presents continuation of the BA Program to supplement insufficient existing revenues for financing the routine operation and maintenance of District facilities and the Ventura Countywide Stormwater Quality Management Program as required by federal NPDES regulations. Additionally, this report outlines the continuation of a benefit assessment component for flood damage repair reserve in Zones 1, 2, and 3 (see Figure 1).

**III. WATERSHED PROTECTION
NEEDS ASSESSMENT AND
AVAILABLE FUNDING**

III. WATERSHED PROTECTION NEEDS ASSESSMENT AND AVAILABLE FUNDING

A. DEVELOPMENT AND FLOOD HAZARD MITIGATION

Over the years, the District has developed and maintained an integrated system of flood mitigation facilities and floodplain management regulations designed to reduce flood damages. Policy makers, in planning community development, have relied upon the existence and effectiveness of this system. Residential, commercial, and industrial developments have been approved on the basis that the dams, detention basins, debris basins, channels, and stabilizing structures be constructed to District standards and maintained in a safe and effective condition. Federal flood insurance requirements are also based upon the effective performance of the system. Construction of the District facilities began in 1944 and has continued up to the present time.

The extreme and unpredictable seasonal range in rainfall that is characteristic of the south coastal region of California, combined with the geographic and geologic conditions, makes Ventura County extremely vulnerable to flooding, water erosion, and mud flow hazards during the winter storm season. Repeated flood disasters in 1969, 1978, 1980, 1983, 1992, 1995, 1998, and 2005 have demonstrated this potential. Sustained economic growth in the region increases the potential for catastrophic economic loss and even loss of life from these hazards. Purposeful measures are necessary to ensure that the chance for catastrophic loss in the local communities and rural areas is minimized.

Ventura County grew at a considerable rate from 1950 to 1980.⁴ During that time as county land use transitioned from farmland to urbanized areas, the District invested considerable funds to create a viable infrastructure of watershed protection facilities such as channels and basins to provide protection from stormwaters for the growing population. According to the Southern California Association of Governments (SCAG), Ventura County's population grew by 12.58% between the 1990 and the 2000 census, making it the fifth fastest growing county in California in terms of population growth--behind only Riverside, Imperial, San Bernardino and Orange counties for that time period.⁵

Figures now show that the growth trend for Ventura County is slowing. Agricultural preservation laws limited some development in the county and citizens have enacted a number of growth controls to preserve farmland and open space. Some growth is still expected in Ventura County, but growth will be the second slowest, higher only than Orange County, as the region looks toward 2025.⁵ Because growth is slowing in the Ventura County region, it is to be expected that historically increasing amounts collected for Benefit Assessment will also level off somewhat. Nevertheless, costs to maintain the older components of the watershed infrastructure, in particular, will increase. Overall costs to maintain the countywide system in general will also increase, taxing already limited revenues.

4. <http://www.scag.ca.gov/resources/pdfs/Counties/VenturaCounty.pdf>

5. <http://www.scag.ca.gov/census/>

B. ROUTINE OPERATIONS AND MAINTENANCE

The District owns and operates significant physical watershed protection infrastructure (channels, dams, levees, basins, etc.). These facilities are generally summarized by zone in Table 1 (watershed zone boundaries are shown in Figure 1).

For several years the cost of routine operations and maintenance in each zone has exceeded the benefit assessment collected for that purpose. Additional needed funding has come from property tax revenue, normally used for capital projects and advance planning.

C. FLOOD DAMAGE REPAIR RESERVE

Due to the unpredictable nature of the winter weather in Ventura County and frequently experienced flood damage, periodic increases in assessments have been necessary to cover the cost of damage repair. Between 1988 and 1995, three temporary assessment increases were levied to cover shortfalls in O&M funding and State and Federal reimbursements.

In June 1995, a Flood Damage Repair Reserve was established through the BA as a precautionary measure to fund future emergency repairs. The intent was to offset future flood damage repair costs while minimizing the fluctuations in BA rates. The establishment of this fund later proved to be extremely prudent because Article XIII C and XIII D of the State Constitution (formerly Proposition 218) contained no provision for dealing with emergency circumstances. The amount collected for Flood Damage Repair Reserve typically amounts to about \$1 million annually via the BA. This amount varies slightly depending on the values of land use parameters existing at the time the BA is calculated.

When disaster strikes, the District mobilizes in response to ensure continued operation of facilities and to mitigate potential future damage because of the disaster. Continued augmentation of this Reserve component ensures that the District has funds available to repair damaged facilities and to implement mitigation measures in a timely manner. A Presidential disaster declaration authorizes federal funds to provide disaster and mitigation assistance under several State and Federal programs. While these programs often reimburse a considerable amount of costs associated with the disaster, the District remains responsible for the required local match share and for any ineligible project costs. Flood Damage Repair Reserve funds have been used since Fiscal Year 1999 to cover any costs for the restoration of facilities damaged in the 1998 and 2005 storms not covered by State or Federal funding or by the Emergency Flood Damage Repair component of the BA Program.

The Flood Damage Repair Reserves were depleted completely after the 2005 flood disaster and it may be several more years before the difference between the District's expenditures and FEMA/OES reimbursements will be recovered through the Benefit Assessment.

D. NATIONAL POLLUTANT DISCHARGE ELIMINATION SYSTEM (NPDES) STORMWATER REGULATION

This portion of the District BA Program provides needed revenues for the implementation of the Countywide NPDES Stormwater program. Assessments are levied based on the proportion of stormwater a parcel of land contributes to the overall stormwater runoff. Urbanization and other man-made alterations to the natural environment can significantly increase stormwater runoff, thereby increasing downstream flows into storm drains operated by the County, the District, and the Cities in the County. Summaries of these BA rates and an estimate of the needed revenue are presented in Tables 3 through 6.

NPDES is a federally mandated program established by the United States Congress with 1972 amendments to the Federal Water Pollution Control Act (known as the Clean Water Act or CWA). The CWA provides a statutory basis for the control of pollutants to the waters of the United States by requiring dischargers, including municipalities to obtain a NPDES permit which identifies and implements structural and non-structural Best Management Practices (BMPs).

The powers granted to the District include carrying on technical and other investigations, examinations and tests of all kinds, making measurements, collecting data and performing analyses, studies and inspections pertaining to water supply, control of floods, source identification, regulation and prevention of contamination and pollutants of surface waters within the District. The District owns, operates, and has regulatory jurisdiction over improved and natural channels to which the ten cities' and the County's storm drains are tributary. On March 31, 1992, the District's Board approved the concept of a cooperative agreement for a Municipal Stormwater Discharge Permit for the Calleguas Creek Watershed. Similar approvals soon followed for the remaining watersheds within the County.

On April 14, 1992, it was decided by Board resolution that the District's BA program would be the primary mechanism to finance a countywide stormwater program to meet federal NPDES requirements for the various municipalities within the District. The District would act as the Principal Co-permittee. City-by-city all ten incorporated jurisdictions joined into the program, although at present not all are financing their programs through the District's BA.

On May 7, 2009, the District, County of Ventura, and the ten Cities of Ventura County (Co-permittees) were issued their third NPDES permit for publicly owned municipal storm drain systems in Ventura County and within their jurisdiction. This permit established a series of requirements to be completed over the next five years. Although the Co-permittees' cooperative approach to countywide implementation of permit requirements continues to result in substantial savings to the residents of Ventura County, the NPDES program's costs continue to exceed Co-permittees' funding.

The County of Ventura and the Cities in the County (Co-permittees) also own and operate stormwater facilities subject to the countywide NPDES program. As in previous years most of the cities have requested that the District collect an assessment through the

BA Program to finance portions of their NPDES programs. The County of Ventura collects an assessment for these purposes in the Ventura River/Ojai Valley (District Zone 1) and the Santa Clara River Valley/Oxnard (District Zone 2) areas for FY2011. Due to voter approval of “Proposition 218”, any new or increased benefit assessments of the Calleguas Creek watershed (District Zone 3) and Hidden Valley/Lake Sherwood/Oak Park (District Zone 4) areas is prohibited. Therefore, the County as a Co-permittee representing the unincorporated area will not receive assessments to fund its NPDES programs for the unincorporated area within the District’s Zones 3 and 4 for the current fiscal year. Also, despite increasing program costs, the County, as Co-permittee, is prohibited from increasing assessment rates established in 1997 in Zones 1 and 2 due to Proposition 218’s restriction to rate increases.

Tables 3 through 6, show revenue slated to offset a major portion of the countywide NPDES program for FY2011. These funds are collected to perform permit compliance activities, including the District-wide share of approximately \$1.44 million. In addition, the Co-permittees (with the exception of the City of Moorpark and the County of Ventura) collectively receive \$1.66 million to help fund the costs of implementing various permit-required activities within their jurisdictions.

The countywide program for FY2011 includes the following elements:

1. Countywide NPDES Program Administration

The Ventura Countywide Stormwater Quality Management Program works cooperatively to ensure compliance with the countywide Stormwater Permit through the development and implementation of an integrated, effective and fiscally responsible stormwater quality management program with the objective of protecting and improving water quality in Ventura County.

The District manages the administration, financial accounting and preparation of all annual reports, internal audits and other documents for submittal to the Regional Water Quality Control Board, Los Angeles (RWQCB) as required by the Permit.

2. General Public Outreach and Education

The District administrates a Public Outreach Program on behalf of the Countywide Stormwater Program. Through the “Communities for a Clean Watershed” campaign, the Program, assisted by a consultant, prepares materials such as TV, radio print and web advertisements, and educational brochures to educate the public on water quality issues and the role of stormwater runoff to the health of receiving water bodies.

The Public Outreach Program is designed to implement and evaluate a comprehensive short- and long-term public education campaign that will inform the community about how our actions may adversely impact urban stormwater discharges and, subsequently, the local water bodies. Public Education is an essential and required part of a municipal stormwater program because changing public behavior can create a real reduction in pollutants. When a community has a clear understanding of where the pollution comes

from, how it can affect them and what they can do to stop it, they will be more likely to change their own practices and help educate others.

3. Municipal Staff Training

Training is important for the implementation of the Stormwater Program. An effective training program is one of the best pollution prevention BMPs that can be implemented because it prompts behavioral changes that are fundamentally necessary to protect water quality. Each Permittee targets staff based on the type of stormwater quality and pollution issues they typically encounter during the performance of their regular activities. This includes staff directly involved preventing pollution, such as inspectors and field crews, and those indirectly involved such as planners and development engineers.

4. Illicit Discharge Program

Illicit connections and illicit discharges (IC/ID) can be concentrated sources of pollutants to municipal storm drain systems. To reduce this source of pollutants the Permittees have developed and implemented programs for the identification and elimination of ID/IC. Key components of these programs are public reporting, field screening, incidence response, education, and enforcement actions.

5. Clean Business Program

The daily activities of many businesses create a potential for pollutants to enter a storm drain system. The Permittees are addressing this source of pollutants through inspections of targeted businesses through educational outreach and enforcement if needed. These efforts include providing information on the potential for illicit discharges and illegal connections from businesses, aid in the selection and use of proper BMPs, and formal enforcement action and fines if environmental rules are ignored.

Permittees target restaurants, automotive repair facilities, industries subject to the state Industrial General Stormwater permit and mobile service businesses (surface cleaning, car washing, carpet cleaning, pool maintenance, etc.) for educational outreach on stormwater and illicit discharges.

6. Stormwater Ordinances

Permittees are reviewing their local ordinances to be in compliance with the third term Permit and are enforcing the current ordinances to protect water quality.

7. Public Agency Activities Program

The Permittees own and operate public facilities, and build and maintain much of the infrastructure of the urban and suburban environment throughout their jurisdictions. Some programs help remove pollutants before they reach receiving waters and others focus on source control ensuring activities performed do not contribute to stormwater pollution to the maximum extent practicable. Therefore public agencies have a dual role in removing pollutants before they are transported by the storm drain system and

preventing pollution from being generated in the operation and maintenance of these facilities.

8. Planning and Land Development Program

The addition of impervious areas for homes, industrial and commercial businesses, parking lots, and streets and roads increases the amount of stormwater runoff, as well as the potential for pollution. The Planning and Land Development Program ensures that the impacts on stormwater quality from new development and redevelopment are limited through implementation of general site design measures, site-specific source control measures, low impact development strategies and treatment control measures. The general strategy for development is to avoid, minimize, and mitigate (in that order) the potential adverse impacts to stormwater. The potential for long-term stormwater impacts from development is also reduced by requiring ongoing operation and maintenance of post-construction treatment controls.

9. Construction Site Program

During construction projects a number of activities may generate or mobilize pollutants. Using inspection, education and enforcement the Development Construction Program coordinates resources to effectively reduce pollutants in runoff from private construction sites during all construction phases

10. Stormwater Quality Monitoring

The District, on behalf of all the Permittees, conducts monitoring of water chemistry, toxicity and biologic function of creeks, rivers and channels throughout Ventura County. Three Mass Emission stations and eleven Major Outfall stations are monitored in both wet and dry weather. Mass Emission stations are located in the lower reaches of the three major watersheds in Ventura County (Ventura River, Santa Clara River, and Calleguas Creek). Major Outfall stations, a new component of the Stormwater Monitoring Program, are located in catchments representative of each Permittee's contribution to downstream waters. Results of the sampling are analyzed to produce pollutant load estimates, identify pollutants of concern, evaluate receiving water quality impacts, and to produce an annual water quality summary report.

The District also participates in several special studies as required by the Permit including a Southern California Regional Bioassessment Study to determine the overall health of local streams, and a Pyrethroid Pesticide study to identify impacts of new products.

E. SUPPORT SERVICES

The construction, operation, and maintenance of Watershed Protection facilities require a variety of related support services, discussed below:

1. Project Design and Inspection - Most District capital projects are designed and inspected by District personnel, with construction performed under private contracts.
2. Watershed Protection Planning and Hydrology - District engineers, as well as numerous outside engineers and agencies, use hydrologic calculations of peak flood flows in the design of Watershed Protection facilities. The District also maintains sophisticated flood warning systems in critical flood hazard areas such as Sespe Creek, Calleguas Creek, and Ventura River that are utilized extensively during flood operations in the winter months and fire condition in the summertime.
3. Geographic Information System (GIS) - Ventura County Watershed Protection District staff are defining and creating GIS coverage for District rights-of-way, permits, facilities, flood plain maps, etc. with the goal of providing engineers and the general public useful information in a timely manner.
4. Benefit Assessment Implementation - The law permits the use of BA revenues to fund the cost of calculating assessments and preparing the roll.
5. General Administration - This includes the normal management, clerical, and accounting functions associated with District operations and maintenance and construction.

F. REVENUE SOURCES

Present major sources of revenue are discussed below:

1. **Property Taxes** - It is assumed that the District will continue to receive a portion of the property taxes collected on the basis of 1% of the assessed value as prescribed in Article XIII A of the State Constitution. State's Budget crisis impact (if any) is unknown at this time.
2. **Land Development Fees for Watershed Protection** - The District has collected land development fees for the design and construction of Watershed Protection projects since 1967 in Zone 3, and 1979 in all other zones. Fees are presently \$2400/acre or \$600/single family dwelling. Under the Flood Control (Watershed Protection) Act, as amended, these figures may fluctuate slightly based on current costs of construction; however the District does not have authority to collect more than \$2,400/acre or \$600/single family dwelling for Land Development Fees. The capital improvement program, including design and inspection, is financed by District property tax revenues and by land development fees.

Fiscal Year 2009-2010, spanning July 1, 2009 through June 30, 2010, resulted in \$181,870 for District-wide land development fees. The District has so far collected \$71,331 for the first seven months of FY 2010 - 2011 as property is being developed. As a comparison, the District-wide land development revenue for FY2010 - 2011 has so far averaged \$10,190 per month over a seven month period and revenue for FY2007-2008, averaged \$72,539 per month. It is clear that the

downward trend seen in recent years will continue, leaving the District with less funding from this source now and into the future.

G. REVENUE DEFICIT

The economic squeeze generated by cost inflation and the tax reduction of Proposition 13, together with the property tax shift from special districts to schools in previous years, require that the District drastically cut back on capital project construction. The District-wide capital project budget in FY1978, for instance, was approximately \$8.6 million, and in FY1988 (before the first BA Program) the budget for District capital projects was less than \$5.4 million. The financial reality concerning District funding is that a shortfall exists between costs and revenues- a shortfall that will likely expand in the future.

**IV. DISCUSSION OF
EXISTING BENEFIT
ASSESSMENT PROGRAM**

IV. DISCUSSION OF EXISTING BENEFIT ASSESSMENT PROGRAM

A. PROPORTIONATE STORM WATER RUNOFF

The purpose of the existing BA program is to provide needed revenues for the District to manage stormwater. The concept of levying assessment based on storm water runoff was particularly pertinent where District services are involved. Most all manmade uses increase storm runoff over that which would otherwise occur naturally and, consequently, increases downstream flood hazards.

Some human uses of the land increase stormwater runoff at a greater rate than others. Stormwater runoff from a shopping center with a high percentage of roofs and parking lots will be greater than runoff from a golf course of equal size with large amounts of grassy areas and landscaping. This proportional difference in runoff was the basis for computing existing BA fees.

B. THE BASIC ASSESSMENT UNIT

In order to establish the "proportionate" storm water runoff on any one parcel of land in relation to total runoff, it was necessary to establish a benchmark to relate that one parcel to all others. This benchmark is called the Basic Assessment Unit (BAU).

The existing BA program for Watershed Protection uses a single family dwelling (sfd) on 0.2 acres of land with an imperviousness factor of 0.40 (40%) as the Basic Assessment Unit (see Figure 2). A single-family dwelling represents a reasonable middle-ground of all potential land uses, as well as the most numerous type of use. The basic assessment unit may be expressed numerically as follows:

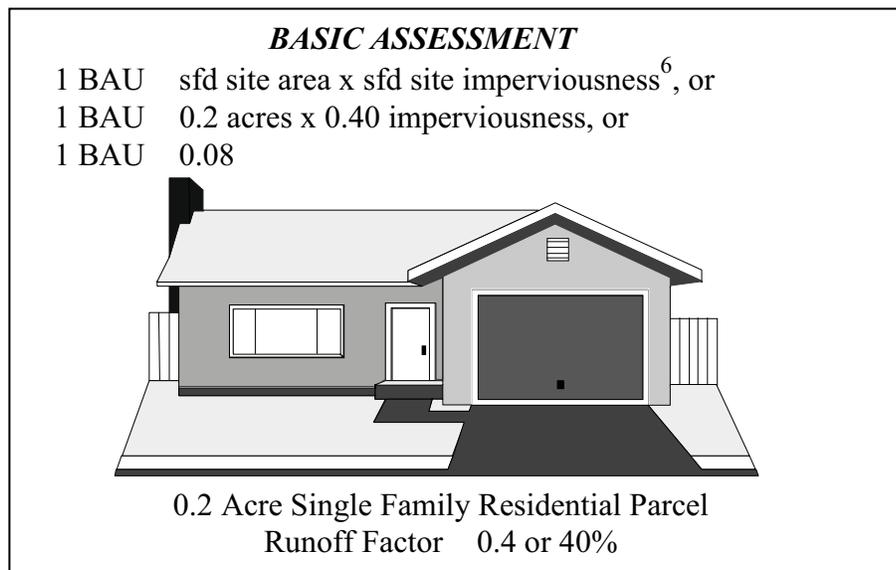

FIGURE 2: All parcels may be equated to the number of BAUs they contain.

6. This is determined by multiplying one acre by the site imperviousness and dividing by one basic assessment unit.

Example:

1 acre of commercial	$\frac{1 \text{ acre} \times 0.88 \text{ imperviousness}}{1 \text{ BAU (0.08)}}$	$\frac{0.88}{0.08}$	11 BAU per acre
----------------------	--	---------------------	-----------------

C. LAND USE AND AREA

The basic factors needed to relate any one parcel of land to the BAU are site use and area. The best available source of this information is the County Assessor's Office. The County Assessor's master property file is a computerized source of both the use and the area of each parcel of land in the County. The file gives each parcel a four-digit site use code. Each of the site use codes used in the program have been analyzed and assigned an imperviousness factor as well as an assessment formula as discussed below (also see Appendix "A"). The District has made minor modifications to the site use codes on the Assessor's Master property file in order to more accurately reflect the level of imperviousness of each use.

D. ASSESSMENT FORMULAS

Where the assessor site use code describes the entire use to be expected on a parcel, the number of BAUs for that parcel is calculated as follows:

$$\begin{array}{l} \text{Number of Basic} \\ \text{Assessment Units} \\ \text{or } (AA \times SI) / 0.08 \end{array} \quad \frac{\text{Parcel area (AA) x site imperviousness (SI)}}{1 \text{ Basic Assessment Unit (0.08)}}$$

A more convenient expression of the basic formula is shown here⁵:

$$(\text{BAUs per acre}) \times (\text{Parcel Area})$$

Actual assessments are calculated by multiplying BAUs by the rate per BAU established for each zone:

$$\begin{array}{l} \text{Assessment} \\ \text{for parcel} \end{array} \quad \begin{array}{l} \text{Total BAUs} \\ \text{for applicable zone} \end{array} \quad \times \quad \begin{array}{l} \text{Existing Assessment rate per BAU} \end{array}$$

1. Single-Use Formulas:

Seven of the formulas used in the program were created using the above format⁶. Each is shown below with the general land use categories to which they apply and the imperviousness factor for each.

A - Condominiums

$$\begin{array}{l} \text{BAUs} \\ (0.72 \text{ impervious}) \end{array} \quad 9 \text{ BAUs / Acre} \times \text{AA (Parcel area in acres)}$$

B - Rest Homes, Churches, Schools

$$\begin{array}{l} \text{BAUs} \\ (0.6 \text{ impervious}) \end{array} \quad 7.5 \text{ BAUs / Acre} \times \text{AA}$$

C - Residential

BAUs 5 BAUs / Acre x AA
(0.4 impervious)

D - Commercial/Industrial

BAUs 11 BAUs / Acre x AA
(0.88 imperviousness)

E - Golf Courses, Greenbelts

BAUs 2.5 BAUs / Acre x AA
(0.2 imperviousness)

F - Vacant Land, Mining, Oil Wells

BAUs 0.125 BAU / Acre x AA
(0.01 imperviousness)

G - Agriculture

a. BAUs 0.2375 BAU / Acre x AA
(0.019 imperviousness)

b. Examples of Calculating Basic Assessment Units using
Single Use Formula

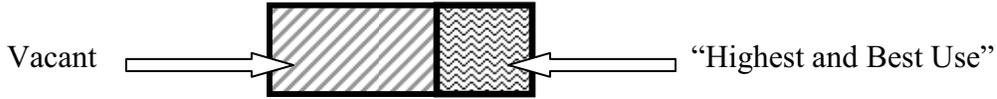

- A 5.0 acre multi-tenant neighborhood shopping center
(site use code 5030)
From Appendix A: 0.88 imperviousness, Formula D.

BAUs 11 BAUs /Acre x 5.0 acres
55 BAUs

- An 80 acre orchard (site use code 8030)
From Appendix A - 0.019 imperviousness - Formula G.

BAUs 0.2375 BAU / Acre x 80 acres
19.0 BAUs

2. Mixed-Use Formulas:

a. Formulas Involving Residential Mixed Uses

Where a site use code was found to describe only a portion of the actual parcel it was necessary to develop a "mixed" assessment formula. The "other" use not described by the site use code is considered to be vacant land⁷. The mixed-use formulas are as follows:

$$\text{Number of Units} \quad \text{BAUs representing Highest and Best Use} \quad + \quad \left(\left[\text{Parcel Area} - \text{Area of Highest \& Best Use} \right] \times \text{BAUs per acre of remaining vacant portion of parcel} \right)$$

In the case of mixed-use parcels with site use codes describing single family dwellings (up to 4 dwellings on one lot) it is appropriate to assign one basic assessment unit to each dwelling and assume any remaining portion is vacant land. Four formulas were developed to accommodate these types of site use codes:

H - 1 Dwelling Unit

$$\text{BAUs} \quad 1 \text{ BAU} + [(\text{AA}-0.2 \text{ acres}) \times 0.125 \text{ BAU/acre}]$$

I - 2 Dwelling Units

$$\text{BAUs} \quad 2 \text{ BAU} + [(\text{AA}-0.4 \text{ acres}) \times 0.125 \text{ BAU/acre}]$$

J - 3 Dwelling Units

$$\text{BAUs} \quad 3 \text{ BAU} + [(\text{AA}-0.6 \text{ acres}) \times 0.125 \text{ BAU/acre}]$$

K - 4 Dwelling Units

$$\text{BAUs} \quad 4 \text{ BAU} + [(\text{AA}-0.8 \text{ acres}) \times 0.125 \text{ BAU/acre}]$$

7. "Mixed-use" formulas may apply depending on a particular parcel's size. See D-2, Mixed Use Formulas on following page and Appendix "A".

Where the actual parcel size is less than that of the assumed number of basic assessment units then the Group "C" formula is used

b. Examples of Calculating Basic Assessment Units using Residential Mixed Use Formulas

- Two single family dwellings on a 10 acre lot (site use code 1222)
From Appendix A: 0.40 imperviousness, Formulas C&I

Formula "I"

$$\begin{aligned} \text{BAUs} &= 2 \text{ BAUs} + [(10 \text{ acres} - 0.4 \text{ acre}) \times 0.125 \text{ BAU} / \text{Acre}] \\ &= 2 \text{ BAUs} + 1.2 \text{ BAU} \\ &= 3.2 \text{ BAUs} \end{aligned}$$

- A four family dwelling (quadplex) on a 0.6 acre lot
(site use code 1410)
From Appendix A: 0.40 imperviousness, Formulas C&K

Formula "C"

$$\begin{aligned} \text{BAUs} &= 5 \text{ BAUs} / \text{Acres} \times 0.6 \text{ acres} \\ &= 3 \text{ BAUs} \end{aligned}$$

c. Formulas Involving Urban Mixed Uses

In researching site use codes and actual land uses, it was found that "mixed" uses also existed in types of land use other than residential. These additional "mixed" formulas were created to accommodate the unique circumstances of certain types of use:

L - Churches, Private Schools, Colleges, Rest Homes and Camps with areas over 2 acres
(0.6 imperviousness)
$$\text{BAUs} = 15 \text{ BAUs} + [(AA - 2.0 \text{ acres}) \times 0.125 \text{ BAU} / \text{Acre}]$$

M - Golf Courses, Green Belts
(0.2 imperviousness)
$$\text{BAUs} = 30 \text{ BAUs} + [(AA - 12.0 \text{ acres}) \times 0.125 \text{ BAU} / \text{Acre}]$$

N - Mobile Home Park
(0.72 imperviousness)
$$\text{BAUs} = 90 \text{ BAUs} + [(AA - 10.0 \text{ acres}) \times 0.125 \text{ BAU} / \text{Acre}]$$

O - Industrial, Resource Production, Greenhouses, Egg Production
(0.88 imperviousness)
$$\text{BAUs} = 110 \text{ BAUs} + [(AA - 10.0 \text{ acres}) \times 0.125 \text{ BAU} / \text{Acre}]$$

d. Examples of Calculating Basic Assessment Units using Urban Mixed Uses

- A church on a 3.5 acre parcel
(site use code 6900)
From Appendix A: 0.6 imperviousness, Formulas B&L

Formula "L"

$$\begin{aligned} \text{BAUs} &= 15 \text{ BAUs} + [(3.5-2.0) \times 0.125 \text{ BAU / Acre}] \\ &= 15 \text{ BAUs} + 0.19 \text{ BAUs} \\ &= 15.19 \text{ BAUs} \end{aligned}$$

- A manufacturing plant on a 20 acre parcel
(site use code 2020)
From Appendix A: 0.88 imperviousness, Formulas D&O

Formula "O"

$$\begin{aligned} \text{BAUs} &= 110 \text{ BAUs} + [(20-10.0) \times 0.125 \text{ BAU / Acre}] \\ &= 110 \text{ BAUs} + 1.25 \text{ BAU} \\ &= 111.25 \text{ BAUs} \end{aligned}$$

E. ASSESSMENT FEES FOR FY2010

The assessment formulas above were intended to provide the most equitable distribution of assessments possible. Assessment rates for routine maintenance and damage repair are shown in Table 2 and for NPDES in Tables 3 through 6. The total assessment for any property is the summation of the rate for the applicable zone in Table 2 and for the applicable rate in Tables 3 through 6. For example, the overall recommended assessment rate of \$36.99 for the City of Ventura in Zone 2 is a combination of the following:

(Roll 14-05)	District Operations and Maintenance -	\$27.13
(Roll 14-30)	District NPDES Compliance in the City of Ventura -	\$3.96
(Roll 14-46)	City of Ventura NPDES Compliance -	\$5.90
	Total:	\$36.99

Table 9 provides a comparison of the total assessment rates assessed for FY2011 with those for FY2010. Table 8 defines assessments for typical land uses in each zone.

F. CALIFORNIA ENVIRONMENTAL QUALITY ACT

The provisions of the California Environmental Quality Act (CEQA), requiring the determination of environmental impacts of projects, do not apply to the establishment of a benefit assessment program according to Section 21080(b) (8) of the Public Resources Code. The purpose of the FY2011 District BA is to meet capital costs and operation and maintenance expenses required to maintain service within existing service areas.

G. APPEAL PROCESS

Assessments may be appealed according to provisions defined by the Board of Supervisors of the Ventura County Watershed Protection District. Generally, these

provisions provide that an assessment may be revised by the Director of the Ventura County Public Works Agency where it can be found that errors have been made in the assessment computation based only on one or more of the following:

1. Changes or corrections in ownership of a parcel
2. Subdivision of an existing parcel into 2, 3, or 4 parcels
3. Use of a parcel
4. Area of a parcel
5. Mathematical computations

Any person who does not agree with the determination of the Director regarding adjustments in assessment calculations may, within 30 days after the date of such refusal, appeal that determination to the Board of Supervisors. The appeal shall be in the form of a written notice and shall be signed by the party aggrieved. The notice shall contain the assessor parcel number(s), the amount of assessment, and the reason for the appeal. At the hearing, the appellant shall have the burden of establishing, to the satisfaction of the Board, that he or she is entitled to a revised assessment; otherwise, the decision of the Director shall stand. The decision of the Board is final.

H. AVAILABILITY OF REPORT AND ASSESSMENT ROLL

This report is available for review at the following location:

Ventura County Watershed Protection District
County of Ventura Government Center
Hall of Administration
800 South Victoria Avenue
Ventura, CA 93009
Telephone: (805) 650-4060 / (805) 650-4073

Appendices B and C are separate volumes included in this final report and are available for review at the offices of Ventura County Watershed Protection District. Inquiries concerning the BA Program, fee calculations, or the appeal process for assessment should be directed to the Benefit Assessment office of the District at the address listed above.

I. DISCUSSION OF NOTICE AND MEETING/HEARING PROCESS

On January 1, 1994, SB 376 became effective establishing new noticing and hearing requirements for local taxes and assessments. This legislation requires that public notice be given for any new or increased taxes or assessments. SB 1977, effective January 1, 1993, requires that an additional public hearing to be held on a date different from the enactment hearing to allow public testimony if there are to be increased amounts. Although rates were held to the same rate as previous years two meetings were held for FY 2011. The first meeting was held on May 11, 2010 as “receive and file” item to The Board of Supervisors to allow for public review of the proposed rates for FY2011. The second meeting was held on June 8, 2010 to allow for public testimony and to put proposed rates up to vote of the Board. The Board of Supervisors of the Watershed Protection District published notice for the public hearing / enactment meeting as an agenda item, time certain. The rates were approved by resolution at the public hearing on June 8, 2010.

City of San Clemente Clean Ocean Program & Fee **Frequently Asked Questions**

What is the Clean Ocean Program?

It is the City's effort to prevent stormwater and urban runoff pollution from entering the storm drain system and being discharged at the beach.

Why does the City need a Clean Ocean Program?

- To protect the environment (water quality in local channels and coastal waters);
- To protect public health and safety (from bacteria and other pollution that could reach the beach);
- To protect local quality of life (local business/tourism, "beach town" reputation, etc.); and
- To meet State Water Code and Federal Clean Water Act permit requirements issued to South Orange County cities by the State.

Who developed the Clean Ocean Program?

The City prepared an Urban Runoff Management Plan (URMP), which included participation and feedback from the community as well as the City's Coastal Advisory Committee (local citizens appointed by the City Council to consider and provide advice on coastal and water quality issues). The URMP guides the Clean Ocean Program, and outlines activities and projects to meet the State and Federal water quality requirements and protect local water quality.

What does the Clean Ocean Program include?

- *Runoff treatment projects*
 - Poche Beach: A treatment system was constructed and is maintained to filter and kill bacteria in the runoff before it reaches the beach. Construction was completed in March of 2009. The system treats up to 1.1 million gallons per day. Weekly water quality tests indicate that the UV treatment removes between 95% - 99% of the bacteria in the storm drain runoff before it discharges to the beach. The current water quality grade at Poche Beach is an A+.
 - North Beach: A system was constructed to divert dry weather runoff away from North Beach and send it to the City's Water Reclamation Plant for treatment. The system started operating on June 1, 2009. It diverts and filters about 350,000 gallons per day. The current water quality grade at North Beach is an A+.
 - Underground storm drain units were installed to remove trash, oil & grease and sediment from runoff before it gets to the beach. Six units have been installed. They are located near Calafia Beach, in the Pier Bowl area, at the west ends of El Portal, at the end of Linda Lane and at Mariposa. In 2013, 35 cubic yards of material was captured and removed by these units. This is material that would have otherwise have ended up in the ocean.
- *Pollution prevention activities*
 - Street Sweeping: the City sweeps public residential streets twice per month and major streets and business areas about 3 times per week. Over 22,000 tons of material has been collected over the last ten several years, enough to fill 550 large (40 cubic yard) trash bins.
 - Catch Basin Inspection and Cleaning: the City inspects at least 2,205 catch basins annually, cleaning them as needed. In 2013, 2,432 catch basins were cleaned and a total of 914 cubic feet of material was removed.
 - Water Quality Testing: water samples from over 20 locations throughout town are sampled each year to help identify potential problem areas and monitor quality progress over time. Flow measurements are also taken to help measure progress in reducing urban runoff flows.
 - Special Studies: the City consulted with scientists to conduct an in depth investigation to find sources of bacteria in the Poche Beach watershed. A year long study which included molecular

City of San Clemente Clean Ocean Program & Fee **Frequently Asked Questions**

marker testing culminated in focused recommendations and a strategic plan for reducing bacteria at Poche Beach. The final report of the study is located on the Clean Ocean Program website at www.sccleanocean.org.

- **Commercial, Industrial and Construction Site Inspections:** Inspections of businesses, industrial facilities and construction sites are conducted to make sure these sites are using proper Best Management Practices (BMPs) to prevent pollution from entering the storm drain system and reaching the beach. Over 9,000 inspections have been completed in the last 10 years.
- **Spill Cleanups and Storm Drain Maintenance:** A 24/7 hotline number (**366-1553**) is in place to respond to and cleanup spills or investigate reported illegal discharges. In addition, the City performs ongoing maintenance to ensure proper function of the storm drain system and inspects all public catch basins annually and removes materials that might be discharge into the system.
- **Enforcement of Anti-pollution Ordinances:** Dedicated officials enforce water quality laws to identify and correct violations. Depending on the severity of the violation, enforcement may include verbal warnings, written correction orders, and/or fines of \$100, \$200, or \$500 per violation.
- **Public Outreach and Education:** Efforts promote awareness of stormwater and urban runoff pollution impacts, and ways the public can help prevent this pollution from happening in the first place.

What is the cost of implementing the Clean Ocean Program?

The cost to implement the program is about \$2.2 million per year.

What is the cost of not implementing the Clean Ocean Program?

The City could be liable for large fines if the State finds that the City is not meeting the requirements of the stormwater permit regulations. Also, there are potential economic impacts (tourism, real estate values, etc.) if the City does not work to protect its healthy beach town reputation.

How is the Clean Ocean Program funded?

By a Clean Ocean utility fee charged to property owners. The fee is collected as a line item on the monthly utility bill for owners that get water service from the City. The fee is charged monthly but collected via a separate twice-yearly bill to San Clemente property owners that get water service from other providers (e.g. South Coast Water District or Santa Margarita Water District).

Why do property owners get charged the Clean Ocean Fee?

Developed and graded properties contribute runoff to the storm drain system (which includes pipes, channels, drain inlets and street gutters). This runoff contains or picks up pollution before it enters the storm drain, which the City must then address. Since providing storm drain and water quality services is like other utility services provided by the City (e.g. drinking water and sewer service), it is appropriate that property owners pay for the cost of this service.

How long will the continued fee be in effect? When will it end?

If approved by San Clemente property owners, the existing Clean Ocean Fee would be continued for an additional six and one-half (6.5) years, and would expire on June 30, 2020.

How much will the fee increase over the next 6.5 years?

The continued Clean Ocean Fee would be fixed and would not increase over the entire period.

Why are property owners voting on this fee?

**City of San Clemente Clean Ocean Program & Fee
Frequently Asked Questions**

Under the provisions of California Proposition 218, property owners must approve new property fees adopted by cities.

What is the change from the existing to the proposed Clean Ocean Fee?

Single Family Residential Monthly Fee		
	Current Fee	Proposed New Fee
Private street	\$ 4.39	\$ 5.10
Public street	\$ 5.02	\$ 6.23

Multi-Family Residential Monthly Fee		
	Current Fee (per residential unit)	Proposed New Fee (per residential unit)
Private street	\$3.51	\$4.08
Public street	\$4.01	\$4.98

Non-Residential (Commercial, Industrial, Business Park) Monthly Fee		
	Current Fee (per acre or fraction thereof)	Proposed New Fee (per acre or fraction thereof)
Private street	\$43.90	\$51.00
Public street	\$50.20	\$62.30
Note: Almost all non-residential streets within the City are public streets.		

Undeveloped, Graded Property Monthly Fee				
	Current Fee		Proposed New Fee	
	<i>2 acres or less</i>	<i>Each acre over 2 add:</i>	<i>2 acres or less</i>	<i>Each acre over 2 add:</i>
Private street	\$2.20	\$0.44	\$2.55	\$0.51
Public street	\$2.51	\$0.50	\$3.12	\$0.62
Note: There is no clean ocean fee charge for undeveloped, ungraded parcels.				

Note: Properties on private streets are charged a lower rate since the City doesn't provide street sweeping service on private streets.

How is the fee calculated?

The fee is based on a parcel's expected contribution of runoff, which is determined by an estimate of the impervious area on that parcel. Impervious areas include such things as buildings and pavement, which prevent or restrict storm water from getting into the soil and increase runoff from a parcel.

Why is the existing Clean Ocean Fee being proposed to be continued?

The fee funds a stormwater quality program that the State requires the City to implement. Since the fee was last approved, the State revised and adopted a new stormwater permit for the south Orange County area that contains more rigorous requirements. Also, the State recently adopted new requirements for bacteria pollution for which the City must comply.

What happens if continuation of the existing Clean Ocean Fee is not approved?

If the Clean Ocean Fee is not continued, the City will need to support the Clean Ocean Program with some other funding source. The most likely source would be the General Fund, which would result in about \$2 million each year that would not be available for other needed projects and programs within the City.

City of San Clemente Clean Ocean Program & Fee **Frequently Asked Questions**

How and when will the vote occur?

All record owners of property within the City that are directly subject to the proposed fee will receive an official mail-in ballot with a postage paid addressed return envelope. The ballots will be mailed to property owners on October 25, 2013. Return ballots are due on December 10, 2013.

How do I cast my vote?

Simply fill out the ballot and mail or deliver it to the San Clemente City Clerk by the due date noted on the ballot.

How do I get more information?

More information about the proposed fee continuation is available on the City's website at www.sccleanocean.org. You may also call the Environmental Programs Section at (949) 361-8204 or send an email to cleanwater@san-clemente.org.

What's the difference between storm drains and sewers – doesn't it all get treated?

Like most other cities, the City of San Clemente owns and operates a storm drain system, which is the network of channels and pipes that collect stormwater and urban runoff and discharges it into the ocean. Unlike sewer systems that send sewage to a treatment plant before being discharged, most storm drain systems, including the City's, were built to collect and convey runoff to prevent flooding but not to treat urban water runoff. Therefore, any pollutants that runoff carries into the storm drain system are discharged untreated along the City's shoreline.

Do other cities have a Clean Ocean Program?

They may call it something else, but all cities in the urbanized areas of Southern California are required by the State to implement stormwater and urban runoff programs to prevent discharges of pollution to creeks, rivers and the ocean.

How do we know that the Clean Ocean Program is working?

- The City records amounts of trash picked up by street sweepers and removed from underground treatment devices.
- Larger treatment projects include monitoring to compare water quality before and after treatment.
- The City tracks the number of enforcement actions and inspections to document these efforts.

Why should San Clemente property owners pay to clean up pollution from upstream cities?

Unlike most cities in Southern California, San Clemente's city boundary is very similar to the local watershed boundary. This means that San Clemente is a self-contained watershed, and that there are no upstream cities that contribute pollution through our local watershed. So the pollution in our storm drains comes from San Clemente properties, and not from out-of-town areas.

How can I help?

To learn about simple tips to help prevent urban runoff pollution, please visit www.sccleanocean.org or www.ocwatersheds.com.

To learn about potential volunteer opportunities (e.g. beach cleanups), please visit www.scwatersheds.com.

City Storm Water Program and Measure E: Clean River, Beaches and Ocean Fund

FY 2015 Highlights

Dedicated funding for programs
to prevent pollution from reaching our waterways
and beaches

Urban Runoff

Rain and urban runoff flows untreated directly into local streams, the San Lorenzo River and Monterey Bay

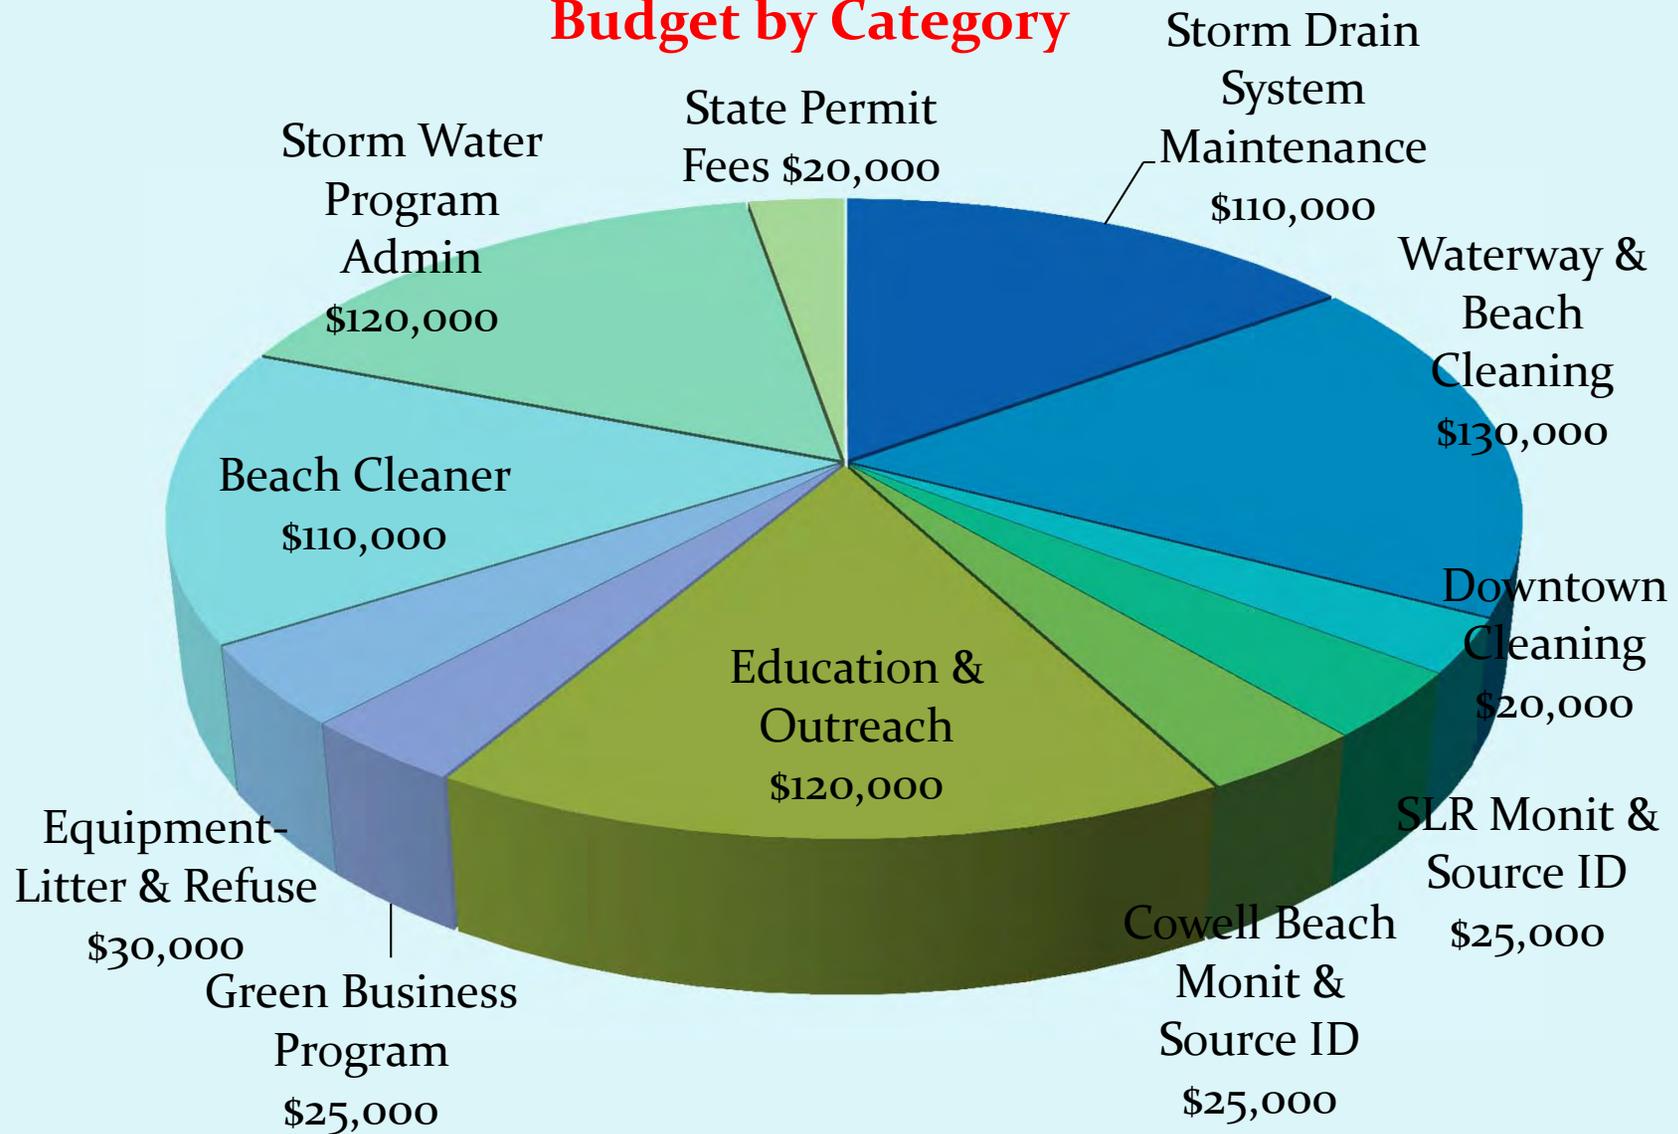

FY 2015 Expenses

- Storm Drain System Maintenance: \$110,000
- Waterway & Beach Cleaning: \$130,000
- Downtown Cleaning: \$20,000
- San Lorenzo River Monitoring & Source ID: \$25,000
- Cowell Beach Monitoring & Source ID: \$25,000
- Education & Outreach: \$120,000
- Green Business Program: \$25,000
- Equipment: Litter & Refuse: \$30,000
- Beach Cleaner: \$110,000*
- Storm Water Program Staff: \$120,000
- State Permit Fees=\$20,000

Revenue: \$630,000 Expenses: \$740,000

FY 2015 Expenses

Budget by Category

Municipal Operations

Focus on cleaning:

To keep debris & pollutants from flowing into the San Lorenzo River and Monterey Bay

- Storm drain pipelines
- Pump Stations
- River Toe Ditches
- Street Catch basins

Municipal Operations

City Crews clean:

- Storm drain pipelines-9 miles
- River pump stations-5 vaults

Municipal Operations

Storm Drain System Inspection & Cleaning:

- Extensive catch basin inspection & cleaning program. All downtown catch basins plus outlying areas inspected & cleaned.
 - Labor costs
 - Vactor Operation
 - Debris Disposal
 - Televising storm drain lines

Cost: \$110,000

Waterway, River Levee & Beach Cleaning

Ongoing Maintenance Efforts:

- San Lorenzo River
 - Parks Temp Staff-\$70,000
 - Contracted cleanups-\$25,000
 - Subtotal: \$95,000
- Cowell & Main Beaches
 - Wharf Temp Staff \$35,000

Cost: \$130,000

Beach Cleaning

Beach Cleaning Machine for Cowell & Main Beaches

Cherrington Beach Cleaner
Cost: \$110,000

Waterway, River Levee & Beach Cleaning

Parks Rangers Temp Staff-cleanups & restoration efforts

Cost=\$70,000

Municipal Operations

Downtown Cleaning: Hand Sweeping-Hope Services

Cost=\$20,000

Municipal Operations

Downtown Cleaning: Alleyways

Cleaned by contractors

River Levee & Beach Volunteer Cleanups

Save Our Shores:

- San Lorenzo River-Adopt a Levee cleanups
- San Lorenzo River-4 seasonal cleanups
- Annual Coastal Cleanup Day-beach & river cleanups
- July 4th & 5-beach outreach & cleanups
- Disposal of debris

Cost=\$25,000

Education & Outreach Program

School Programs:

- O'Neil Sea Odyssey-Field trip & class 4-5th grades
- Save The Whales-K-12th Grade class presentations
- Save Our Shores-Middle & High School assemblies and classes
- ZunZun-Musical Assemblies K-6th grades

Cost=\$35,000

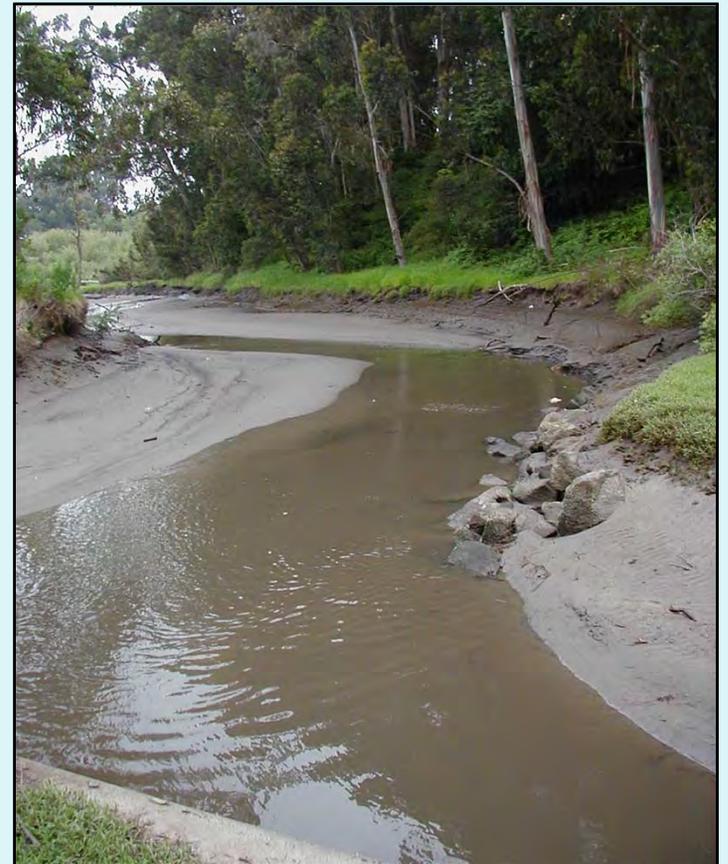

Education & Outreach Program

Volunteer Monitoring & Stewardship:

- CWC Snapshot Day
- CWC San Lorenzo River Alliance

Cost=\$15,000

Education & Outreach Program

Residential Outreach:

- Arana Gulch Watershed Coordinator
- EA-Our Water Our World: pesticides & herbicides
- EA-Green Gardner Program
- RCD-Low Impact Development
- SW agencies-Region-wide TV ads

Cost=\$15,000

Education & Outreach Program

Business Outreach & Recognition:

- City Clean Ocean Business Program
- Monterey Bay Green Business Program
- Green Gardner/
Landscaping Program

Cost=\$30,000

Education & Outreach Program

Litter & Illegal Dumping:

Catch Basin Labeling (SOS)

Cost=\$10,000

Cigarette Butt
“Bait Tank”
containers

San Lorenzo River Pollution Prevention

Litter & Illegal Dumping

- Trash/Recycling and Cigarette Butt containers on SLR levee & other areas

Cost=\$15,000

SLR Watershed Monitoring

State Total Maximum Daily Load Limits: San Lorenzo River

- **TMDL: Bacteria and Sediment**
- State requires monitoring, remedial measures & reports
- Monitoring of SLR, Branciforte & Carbonera Creeks by City Lab & Env Compliance Program
- Results indicate birds and sediment are primary sources of elevated bacteria levels in SLR
- City is an active partner in the SLRA led by Coastal Watershed Council (staff time, funding, specialized lab work, data sharing)

Cost= \$25,000 (Lab)

Cowell Beach

- **City participates in Cowell Beach Working Group**
- **City & County both monitor Cowell Beach**
- **Results show low bacteria levels during winter months**
- **Sewer source unlikely since levels not high year round**

In 2014, City added caffeine test as indicator of sewage (none found so far)
In 2015, City conducted a preliminary bacteria gradient study

New State Requirements

Outfall Inventory and Sampling

- Staff checked 236 storm drain outfalls
- 26 outfalls had flows during summer and were sampled
- Results showed 1 suspect outfall which led staff to identify a cracked storm drain

New State Requirements

Construction: Erosion Control

- Grading ordinance revised June 2014: Projects need to submit erosion & sediment control plans
- Increased PW and Building staff oversight of construction projects

New State Requirements

Development: Low-Impact Design

- New (2014) requirements to collect & infiltrate (sink) storm runoff on property
- Applies to private developments, retrofits, and City projects
- *Examples of LID techniques:*

Pervious Pavement

Bio-retention

Drainage Swale

Rain Barrel

Low-Impact Development on Recent Private Projects

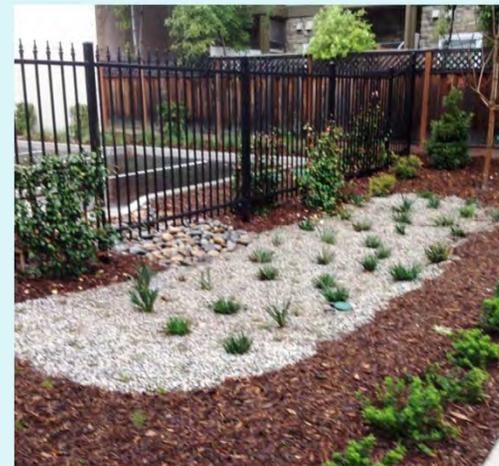

Madrone Street (Sports Authority)

Frederick Street (Multi-family)

West Cliff Drive (Multi-family)

Low-Impact Development on Recent City Projects

Kaiser Permanente Arena

Wharf Roundabout (not vegetated yet)

Arana Gulch Multi-Use Trail

Tannery Arts New Parking Lot

Grants & Projects

State Prop 84 Grant: Low Impact Development Design & Build Parking Lot #9

- Goal to reduce runoff & pollutant loads to River
- LID to sink rain runoff and divert pollutants into soil

Construction completed August 2015

Grants & Projects

State Prop 84 Grant: Low Impact Development Parking Lot #9

- Sloping & curb cuts to bio-swales redirect 75% of lot runoff

Grants & Projects

Bio-swales installed to sink rain runoff & filter pollutants

Vegetated bio-swale with curb cuts

Grants & Projects

Bio-swales installed to sink rain runoff & filter pollutants

Vegetated bio-swale with curb cuts

Grants & Projects

State Prop 84 Grant: Low Impact Development Design & Build Parking Lot #9

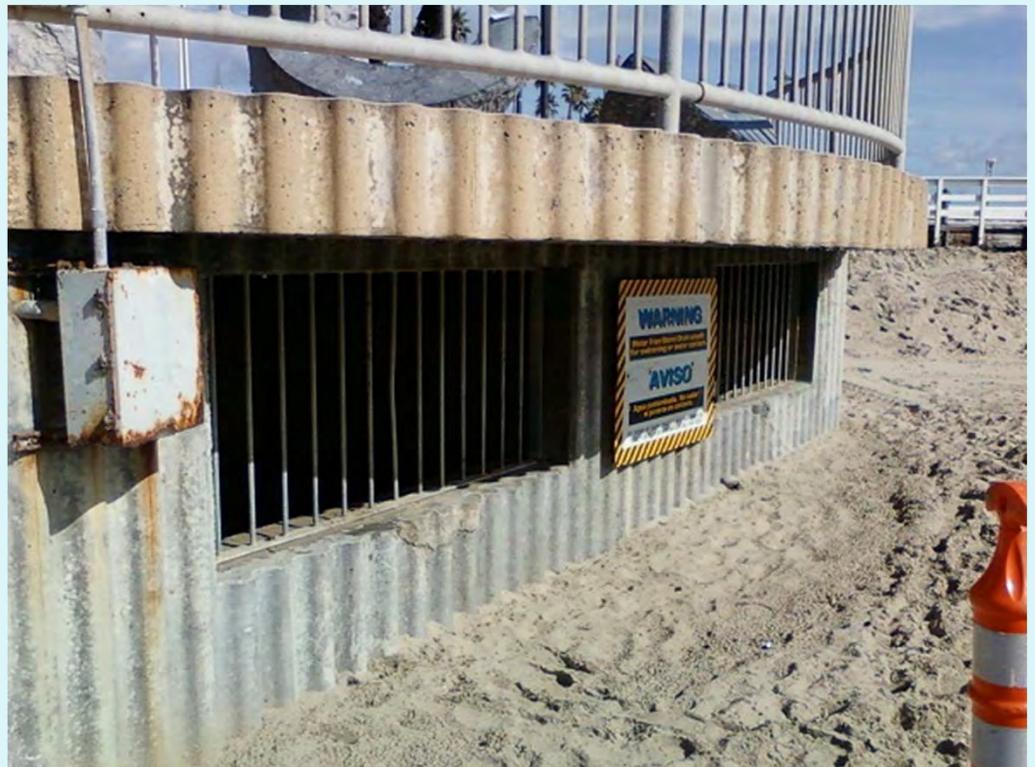

- Lot repaved as part of project
- Match \$40,000 from FY14 budget

Grants & Projects

State Clean Beaches Initiative Grant & CIP Project

- Neary Lagoon Storm Drain Improvement Project
- Goal: Reduce bacteria levels at Cowell Beach
- Storm drain pipes exit at Cowell Beach-buried under sand in summer

Neary Lagoon Beach Outlet Vault

Grants & Projects

Neary Lagoon

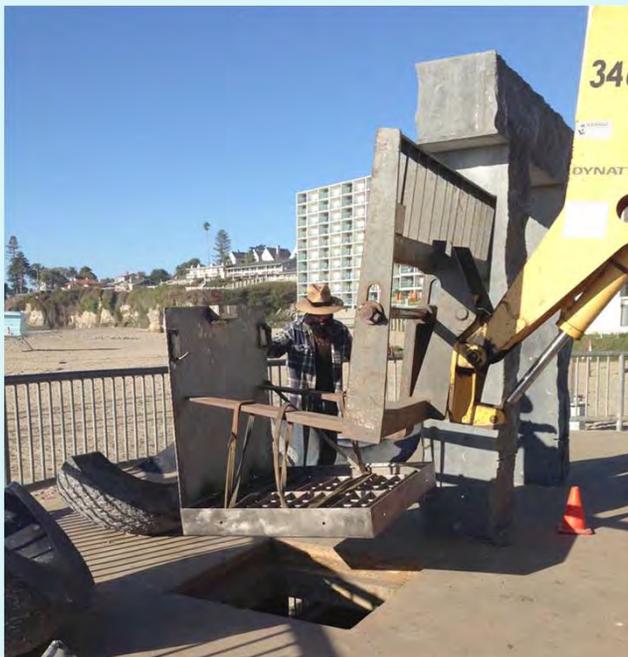

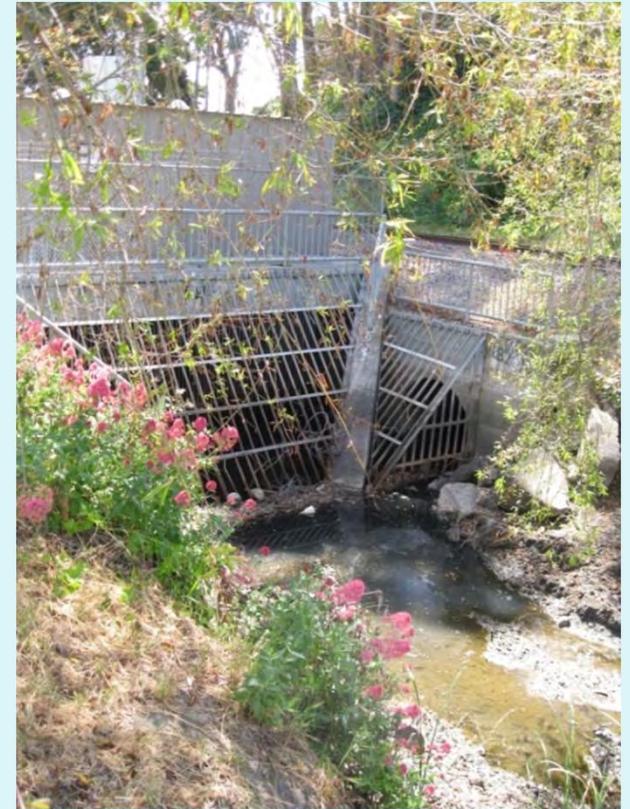

**Gates closed in Summer &
opened in Winter**

Installed Spring 2014

Grants & Projects

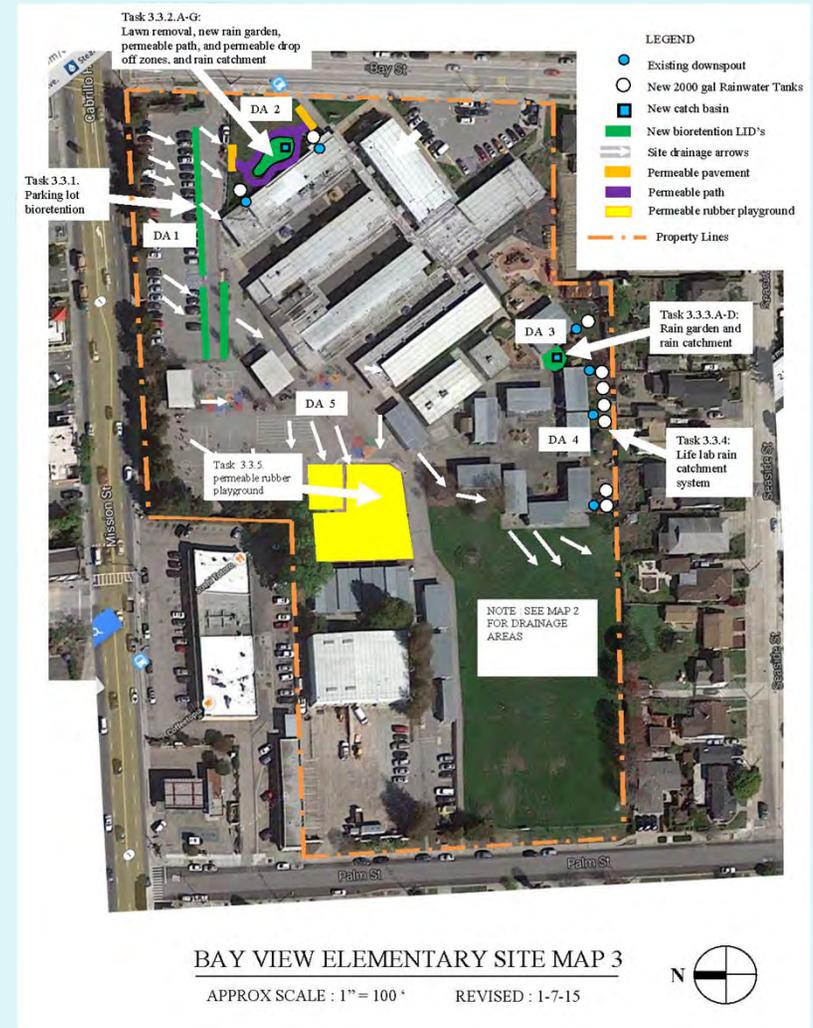

- New hatch at beach outlet vault
- Temp steel plate on gravity pipe opening at beach during summer
- Neary pump station & storm drain lines now cleaned late Spring & Fall

Grants & Projects

State DROPS Grant: Low Impact Design for Schools

- City partnered w/Santa Cruz City Schools and UCSC IDEASS
- \$486,000 Grant Awarded to SC City Schools for Bay View Elementary
- Retrofit LID project: Bio-swales, pervious playground, and rain water catchment/cisterns
- City cost \$15,000 (FY16) towards large rain garden and educational signage

The End

News

Palo Alto proceeds with storm water management fee increase

By **JACQUELINE LEE** | jlee1@bayareanewsgroup.com |

PUBLISHED: August 30, 2016 at 2:48 pm | UPDATED: August 31, 2016 at 7:56 am

PALO ALTO — Money from a proposed increase in storm water management fees would be spent more on operating costs than capital improvements, Palo Alto City Council decided on Monday, reversing a decision made earlier this year.

The council previously approved a resolution calling for a monthly fee of \$13.65, up from \$13.03.

The breakdown of the increased bill was going to be \$6.62 as the base amount and \$7.03 for capital improvements. Now, the allocation is reversed so that \$7.48 is the base and \$6.17 is for improvements.

City staff told council members that initial calculations were off because they were based on fiscal year 2016, rather than 2017, and more money is needed for operating costs.

A public protest hearing on the rate hike is set for Oct. 24. Property owners can file written opposition to the fee increase until then. If a majority does so, then the council has to terminate the fee increase process.

If there is no majority opposition, then the city will conduct a mail ballot election on the fee increase between Jan. 11 and Feb. 28.

If approved, the new fees would go into effect June 1 and generate about \$6.9 million in revenue annually for the next 15 years.

In early 2015, the city identified about \$37 million worth of capital improvements that are needed.

Property owners currently pay about \$12.63 per month in storm drain bills.

Current fees will expire in June. If no action is taken to approve updated fees, then the rates will revert to \$4.25, an amount property owners approved in 2005, which city leaders say is not enough to maintain operations.

Storm Sewer Service Charge

Storm Sewer Service Charge Rate

The Storm Sewer Service Charge rate structure charges users of the storm sewerage system in San José based on the relative quality and quantity of stormwater runoff contributed by residential, commercial, institutional, and industrial properties. The rate structure apportions the costs of storm sewer service to properties in proportion to their relative contribution of flow and pollution to the storm sewer system.

Rates are computed to recover projected costs of the following:

- Stormwater pollution control and permit compliance
- Management, operation, maintenance, and rehabilitation of the storm sewer system
- Improvements to the storm sewer system
- Street sweeping
- Administrative services

Storm Sewer Service Charge rates are reviewed and adjusted annually, as cost and service demand levels change. The current rate structure for storm sewerage services described below became effective July 1, 2011, with San José City Council adoption of Resolution No. 75857 on June 14, 2011. The rates are structured for the estimated cost recovery requirements and the service demand levels of Fiscal Year 2011-12. View the current [residential rates](#) and [commercial rates](#).

For Fiscal Years 2013-14, 2014-15, and 2015-16, no rate increases were adopted. Rates maintain at the same level as Fiscal Year 2011-12.

If you have questions regarding rates for storm sewerage service, please call us at (408) 535-7055.

ATTACHMENT 73

Sewer and Storm Water Fees

The charts below provide information on Sewer Fees and Storm Water Fees in the City of Alameda.

SEWER SERVICE FEE, CITY OF ALAMEDA

	FY2016	FY2017	FY2018	FY2019	FY2020
		% Increase 3.0%	% Increase 3.0%	% Increase 3.0%	% Increase 3.0%
Single Family (\$/month)	\$23.93	\$24.65	\$25.39	\$26.15	\$26.93
Multi-Family (\$/month)	\$21.54	\$22.19	\$22.86	\$23.55	\$24.26
Commercial Fixed Charge (\$/month) (includes first 730 cubic feet)	\$21.54	\$22.19	\$22.86	\$23.55	\$24.26
Flow-Based Rate (\$ per Hundred cubic feet)	\$2.96	\$3.05	\$3.14	\$3.23	\$3.33

STORM WATER FEE, CITY OF ALAMEDA

The Fee is based on the amount of pollution that the City estimates enters the municipal storm water system as a result of the installation or maintenance of impervious surfaces.

2,000 square feet of impervious surface = 1 Impervious Surface Unit (ISU)

The Fee is calculated according to the following formula:

Number of Impervious Surface Units (ISU)

multiplied by

Fee per Equivalent Residential Unit (ERU)

	Storm Water Fee
<p>Typical Single Family Residential Parcel</p> <p>A typical residential parcel has 5,000 square feet of surface area. 40 percent, or 2,000 square feet, is comprised of impervious surface (1 ISU).</p>	<p>\$56.15</p> <p>(1 Equivalent Residential Unit fee)</p>
<p>Condominium (per unit)</p> <p>A typical condo unit has 600 square feet of impervious surface area (0.3 ISU).</p>	<p>\$16.85</p> <p>(0.3 x 1 ERU)</p>

Other parcels with Impervious Surfaces are subject to the Fee based upon stated formula Fee: Number of ISUs multiplied by Fee per ERU.

DECLARATION OF SERVICE BY EMAIL

I, the undersigned, declare as follows:

I am a resident of the County of Sacramento and I am over the age of 18 years, and not a party to the within action. My place of employment is 980 Ninth Street, Suite 300, Sacramento, California 95814.

On September 27, 2017, I served the:

ATTACHMENT 74

MEASURE CW

The Clean Water, Clean Beach Parcel Tax

During the November 8, 2016 Special Municipal Election, Culver City residents voted on Measure CW, the Clean Water, Clean Beach Parcel Tax. The results are as follows: YES - 73.82%; NO - 26.18%.

Funds raised by Measure CW will be used for improvements in water quality in Ballona Creek, Marina del Rey, Santa Monica Bay, and the Pacific Ocean. Measure CW required approval by 2/3 of those voting on the measure to pass.

Need for Measure CW

Dangerous bacteria, pesticides, toxic chemicals, oil and grease, trash and other pollutants are deposited on our roadways and flow into Ballona Creek, Marina del Rey, and the ocean through our storm drains, by rain, and other runoff water. These pollutants harm fish and wildlife, cause illness and infections for swimmers and surfers, and make beaches unsafe and unsightly for families and visitors. The State and Regional Water Quality Control Boards have implemented very strict pollution reduction regulations for storm water runoff. These regulations require the City of Culver City to develop and implement programs to reduce and prevent water pollution.

Purpose of Measure CW

Measure CW establishes an annual Clean Water, Clean Beaches Parcel Tax in the City of Culver City.

Measure CW was placed on the ballot by the City Council of the City of Culver City to create a dedicated source of funding to pay for water quality programs that will prevent pollution from reaching our waterways, beaches and the Ballona Creek Estuary. Measure CW required approval by 2/3 of those voting on the measure.

Cost of Measure CW

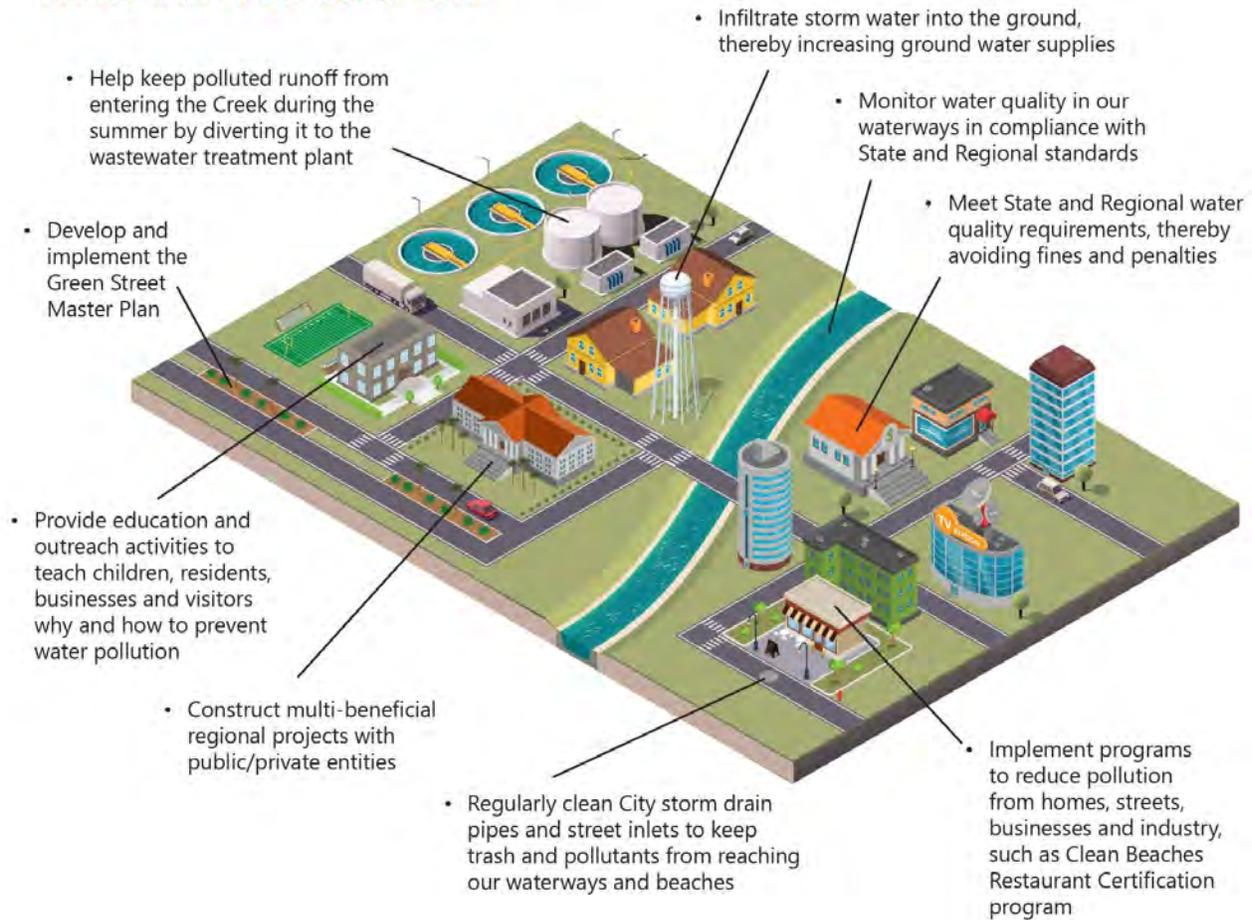

- \$99 annually per single family residential parcel
- \$69 annually per multi-family residential dwelling unit
- \$1,096 annually per acre of land or portion thereof for non-residential

Each parcel owner of a non-residential property will be taxed \$1,096 per acre of land (or portion thereof) annually. The \$1,096 will be pro-rated for non-residential parcels less than one acre. For example, a non-residential parcel of one-half acre will be taxed \$548. Land owners are taxed, not individual businesses located on the non-residential property. For larger parcels with multiple tenants, the land owner will receive one bill based on the size of the parcel, not the tenants.

Tax-exempt parcels will not be charged. Charges will first appear on the tax statements in fall 2017.

Measure CW is expected to generate about \$2 million per year. All Measure CW money will be used here in Culver City to reduce water pollution.

What will it be used for?

Use of Measure CW Funds

Measure CW funds will be placed in a special Clean Water, Clean Beaches Fund, and funds must be used exclusively for reducing and preventing water pollution and managing storm water and urban runoff. The Financial Advisory Committee will oversee how the funds are spent.
